- Unaccompanied personnel housing and related support functions (e.g., school, child development center, youth center).
- Training functions (i.e., classroom instruction and non-live fire training).
- Community support functions.

The areas proposed for the cantonment and housing at AAFB are situated outside of the APZs. Specific and documented procedures would be in place to ensure the public is not endangered by operations and training activities. Therefore, Alternative C would result in no direct or indirect impacts on public health and safety (resulting from operations and training activities).

Explosive Safety

Construction and infrastructure improvements related to the proposed military relocation to AAFB would be consistent with established ESQD arcs on AAFB. However, munitions are transported several times per week from the munitions operations and storage area on NWF to the AAFB airfield along a route to the north and east of the proposed cantonment area. The secondary munitions route traverses the middle of the proposed cantonment area. The long-term risk associated with the transport of munitions adjacent to and through the proposed cantonment area has the potential to cause the evacuation of up to 100% of the cantonment area in the event that a munitions transport incident occurs.

In addition to munitions transportation, another concern is the blast zone associated with the Vehicle Inspection Facility near the North Gate. This gate alignment was developed prior to the consideration of the Marine Corps cantonment area being considered in the same area.

Despite SOPs being in place to ensure the safe transportation of munitions, and incident response procedures in place in the event of a munitions transport incident or explosives incident at the North Gate, a significant direct impact related to explosive safety could occur. Without re-siting the proposed development, this potential significant direct impact cannot be mitigated. By comparison, Alternatives A, B, D, and E would have no impacts associated with explosive safety.

Electromagnetic Safety

Use of AAFB to support cantonment area and housing requirements for relocated Marines would be conducted so that new developments are consistent with established EMR hazard zones. Because electromagnetic emission sources would be operated in accordance with applicable safety standards and the public would be excluded from entering areas where emission sources are located, potential long-term impacts from electromagnetic emissions on public health and safety would not result in any greater safety
risk. Therefore, no direct or indirect impact on public health and safety related to electromagnetic emissions is anticipated.

Construction Safety

Because a health and safety program would be implemented for construction activities and the public would be excluded from entering construction areas, potential short-term construction impacts on public health and safety would not result in any greater safety risk. Therefore, no direct or indirect impact on public health and safety related to construction activities is anticipated.

Environmental Health Effects

Noise

Potential short-term construction and long-term operational noise emissions associated with Alternative C would be similar to those discussed under Alternative A. Enforcement of OSHA guidelines for hearing protection for workers would be the responsibility of the construction contractor. The public would be excluded from entering construction areas. Therefore, short-term construction noise impacts on public health and safety would be less than significant. Long-term operational noise from activities occurring on AAFB would be similar to current noise levels. The area proposed for the cantonment and housing that are south of the airfield are situated within the 60 to 70 dB noise range and are compatible with residential development. Areas north and west of the airfield are within the 65 to 80 dB noise range. These areas would mostly be incompatible for residential development but would allow for operations activities. Construction of buildings in these areas should implement noise level reduction measures to reduce interior noise levels to allow normal conversation. Existing aircraft noise is not at a level that would result in the loss of hearing of cantonment or housing area occupants. Therefore, the overall direct or indirect impacts associated with noise to human health and safety would be less than significant.

Water Quality

Potential water quality impacts associated with Alternative C would be similar to those discussed under Alternative A. Groundwater withdrawal would likely increase. However, sustainability practices would be implemented to reduce the amount of groundwater needed. The resulting total annual groundwater production would be less than the sustainable yield, and monitoring of groundwater chemistry would identify any emerging issues to ensure no harm to the water supply. Water wells on AAFB have a mandated 1,000-foot (305-m) buffer identified as a wellhead protection zone. Proposed development and operational activities would be conducted in accordance with GEPA guidance and BMPs to minimize the potential for contaminants to be introduced in these areas. Therefore, direct and indirect public health and safety impacts from long-term increased demand on potable water and potential water-related illnesses would be less than significant.

Hazardous Substances

Potential direct impacts from hazardous substances for Alternative C would be similar to those discussed under Alternative A. The use, handling, storage, transportation, and disposition of hazardous substances would be conducted in accordance with applicable hazardous material and waste regulations, and established BMPs and SOPs to ensure that the health and safety of workers and the general public is maintained.

IRP investigations and/or remediation activities, as necessary, would continue in an effort to clean up past releases of hazardous substances and receive regulator concurrence that necessary actions have been completed to ensure the safety of the public. No off-site population is near the IRP sites. Building
construction is not proposed within the footprint of IRP sites. Based on investigations of the contaminants associated with sites on AAFB (within proposed cantonment and housing development areas), no health hazards have been identified. Because hazardous substance management and IRP investigative/cleanup activities would be conducted in accordance with applicable regulations and established BMPs and SOPs, no direct or indirect impacts on public health and safety are anticipated.

Unexploded Ordnance

Potential direct impacts from UXO under Alternative C would be similar to those discussed under Alternative A. With the exception of public access provisions outlined through the 2011 PA process (see Section 4.4.10, Cultural Resources), the general public would be excluded from entering construction zones and training areas. To reduce the potential hazards related to exposure to MEC, ESS documentation would be prepared that outlines specific measures that would be implemented to ensure the safety of workers and the public. BMPs would be implemented to identify and remove potential MEC items prior to the initiation of ground-disturbing activities. UXO personnel supervision would occur during earth-moving activities and MEC awareness training would be provided to construction personnel involved in grading and excavations prior to and during ground-disturbing activities. In addition, the DON provides MEC awareness training to GovGuam and other public representatives allowing access to project sites to facilitate surveys or collection of natural resources or items of cultural significance prior to conducting vegetation clearance. Because UXO would be identified and removed prior to initiating construction activities and construction personnel would be trained as to the hazards associated with UXO, potential direct impacts from encounters with UXO would be minimized and less than significant.

Traffic Incidents

Because no high crash frequency intersections are located near AAFB and the overall long-term potential increase in the number of traffic accidents as a result of the increase in personnel would be minimal, there would be a less than significant impact on the health and safety of the citizens of Guam (from traffic incidents).

4.3.18 Environmental Justice and the Protection of Children

4.3.18.1 Affected Environment

As described in Section 4.1.18, the affected environment for environmental justice and protection of children analysis is the entire island of Guam. Therefore, the affected environment for Alternative C is the same as for Alternative A. In addition, the Alternative C is located in the northern area of the island, the same region as Alternative A. The villages of Dededo and Yigo are within this region.

4.3.18.2 Environmental Consequences

Potential impacts to environmental justice populations under Alternative C would be to noise, recreation, socioeconomic and general services (including health services), and public health and safety.

Noise

The potential impacts would be the same as Alternative A.

Recreation

Impacts are generally island-wide and would be the same as described for Alternative A.
Socioeconomics and General Services

Impacts are generally island-wide and would be the same as described for Alternative A, as would the identified measures to mitigate impacts.

Public Health and Safety

Impacts are generally island-wide and would be the same as described for Alternative A, as would the identified measures to mitigate impacts.
4.4 BARRIGADA CANTONMENT/HOUSING - ALTERNATIVE D

Under Alternative D, the proposed development of a cantonment area and family housing would occur at Barrigada. Details about this alternative are provided in Section 2.4.4.4 and the proposed site is illustrated in Figures 2.4-10 and 2.4-11.

4.4.1 Geological and Soil Resources

4.4.1.1 Affected Environment

The affected environment for geological and soil resources under Alternative D is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 3: Geological and Soil Resources, Section 3.1.3.2: Barrigada, page 3-21) which is summarized below for reference. The affected environment for the BEQ/BOQ component of Alternative D located at AAFB is the same as described for Alternative C. In addition, the geological and soils affected environment for projects common to all alternatives (i.e., school expansions and off-site utilities) would be similar to that described under Alternative A. The proposed reduction in the number of relocating Marines and dependents under the 2012 Roadmap Adjustments does not alter the description of the affected environment for geological and soil resources, but it would reduce some potential impacts to geological and soil resources, that were determined to be less than significant or mitigated to less than significant in the 2010 Final EIS, as described in the analysis of environmental consequences for Alternative D below.

The proposed Barrigada cantonment/family housing area is located in the east-central portion of Guam’s limestone structural province (Figure 4.4.1-1). In the northern part of the footprint, the lower slopes of Mount Barrigada rise above the limestone plateau to an elevation of 440 feet (134 m) above MSL (Figure 4.4.1-2). Within the rest of the Alternative D footprint, land slopes gently downward toward the southwest. Barrigada bedrock consists primarily of young (Mariana) limestone with some older (Barrigada) limestone underlying the northwestern corner of the footprint (Figure 4.4.1-1). Similar to Finegayan, the limestone bedrock underlying is the geologic setting for sinkhole formation (see Section 3.1.1.1). Based on available topographic and field data, there are 15 features that have been preliminarily identified as sinkholes/depressions that may contain sinkholes in the Alternative D footprint.

The majority of the Barrigada footprint is covered by three soil types, Guam Cobbly Clay Loam, Pulantat-Chacha Clay, and Cha-Cha clay (Figure 4.4.1-2; Young 1988). Guam Cobbly Clay loam is shallow (less than 9 inches [25 cm] deep) well-drained soil. This soil has a “low” erodibility factor and is not prime farmland (Young 1988). Pulantat-Chacha Clay contains two subgroups that often occur near one another, but have different properties. The Pulantat soils are shallow, well-drained clays that have a slight water erosion hazard, while the Cha-Cha clays are deeper, poorly drained, and have a moderate erosion hazard. Ritidian-Rock Outcrop Complex soils cover a small area on the slopes of Mount Barrigada. These soils are shallow, well-drained and stony, with limestone bedrock outcrops. Shallow slopes of the limestone plateau protect the Guam Cobbly Clay Loam, Pulantat-Chacha Clay, and Cha-Cha clay from erosion. On the steeper slopes of Mount Barrigada, runoff is very slow and the water erosion hazard of the Ritidian-Rock Outcrop Complex is slight (Young 1988).
Figure 4.4.1-1
Geologic Features in the Vicinity of
Barrigada Cantonment/Housing Alternative D

NAVFAC Pacific 2013; Taborosi 2004; WERI 2001
Figure 4.4.1-2
Soils in the Vicinity of Barrigada Cantonment/Housing Alternative D

Sources: NAVFAC Pacific 2013; NRCS 2006
Prime farmland soils, as defined by the USDA, are soils best suited to producing food, seed, forage, fiber and oilseed crops, favorable for economic production and sustained high yield, with minimal inputs of energy and resulting in least damage to the environment (Young 1988). None of the soils in the proposed project area are identified as prime farmland by the USDA. However, the Pulantat-ChaCha clays are capable of supporting agriculture (see Figure 4.4.1-2; Young 1988).

With respect to geologic hazards (see Section 3.1.1.1) there are no known bedrock faults mapped within the Alternative D footprint (see Figure 4.4.1-1). The overall likelihood for landslides at Barrigada is low due to the general lack of steep slopes. The consolidated limestone bedrock at Barrigada is not subject to liquefaction because it does not lose cohesiveness in response to ground shaking during an earthquake. The lowest elevations (approximately 235 feet [71 m]) at Barrigada in the Alternative D footprint are higher than the maximum observed wave vertical run-up for tsunamis recorded for Guam. Thus, the Alternative D site is not subject to tsunami inundation. The limestone bedrock in the area of Alternative D presents a potential hazard of surface instability and collapse due to sinkholes.

4.4.1.2 Environmental Consequences

Potential geology and soil impacts addressed in this section are limited to elements of the proposed action that could affect onshore landforms or that could be affected by geologic hazards. Potential soil contamination issues are addressed in Section 4.4.16.2 of this SEIS (Hazardous Materials and Waste).

Construction

Construction of the new cantonment/family housing, associated support facilities, and roads associated with Alternative D would include the same activities as described for Alternative A.

Grading for construction of the cantonment/family housing areas and associated infrastructure would include 3,510,000 yd³ (2,683,589 m³) of cut (excavation) and 2,618,000 yd³ (2,001,606 m³) of fill, resulting in a net of 892,000 yd³ (681,983 m³) of cut material available for use as needed. Similar to Alternative A, the volume of excavation and fill would be used to level minor irregularities in the limestone surface to create a buildable surface for the construction of buildings, parking lots, and roadways, and is not anticipated to create major elevation changes. Alternative D would involve the second largest excavation volume of the five action alternatives for the cantonment and family housing (Alternative E would be the largest). The only development proposed in the northern, steeper portion of the Barrigada footprint would be construction of a water tank (see Figure 2.4-10 in Section 2.4.4.4 of this SEIS). Construction of this tank would involve minimal excavation and so would not result in a significant impact to topography. Therefore, with construction of Alternative D there would be a less than significant direct long-term impact to topography and slope stability, similar to that described for Alternative A.

Under Alternative D, the same construction activities would take place as under Alternative A, in similar geologic, soil and seismic conditions. Although some soil types are different at Alternative D (Pulantat-Cha-Cha clay) the overall topography and soil characteristics are similar: low to moderate erodibility and no prime farmland. The same BMPs described for Alternative A would be implemented for Alternative D. Therefore, under Alternative D, the construction impacts would be similar to those for Alternative A: less than significant direct short-term impacts to soils from erosion, and no direct or indirect impact to agricultural soils. Given compliance with 22 GAR Chapter 10 § 10106F, there would be no adverse impacts to sinkholes, so direct short-term impacts to sinkholes would be less than significant. Direct and indirect impacts associated with geologic hazards would be less than significant.
Construction impacts for the BEQ/BOQ located at AAFB would be similar to those described for Alternative C.

Under Alternative D, construction of the utility and school expansions that are common to all alternatives would comprise the same activities, and would occur in similar geologic, soil, and seismic conditions as for Alternative A. The same BMPs described for Alternative A would be implemented for Alternative D. Therefore, under Alternative D, the construction impacts of these components would be similar to those for Alternative A.

Operation

Under Alternative D, the same residential, recreational, commercial, and administrative uses would take place at Barrigada as under Alternative A, where geologic, soil and seismic conditions are similar to those of Alternative A. Ground disturbance would be minimal and would take place on land that was previously disturbed during the construction phase. No prime farmland is identified within the Alternative D project footprint, so there would be no direct or indirect impacts to agricultural soils as a result of Alternative D operations. The same erosion minimization measures, sinkhole BMPs and seismic design requirements, described for Alternative A would apply to Alternative D. Therefore, with the operation phase of Alternative D there would be no direct or indirect impacts to topography and slope stability, and less than significant direct long-term impacts to soils from erosion. Given compliance with 22 GAR Chapter 10 § 10106F, there would be no adverse impacts to sinkholes. This would minimize potential geologic hazards associated with sinkholes and reduce potential direct long-term impacts to sinkholes to less than significant. Direct and indirect impacts associated with geologic hazards would be less than significant.

Operation impacts for the BEQ/BOQ located at AAFB would be similar to those described for Alternative C.

Under Alternative D, operation of the utility and school expansions that are common to all alternatives would comprise the same activities, and would occur in similar geologic, soil, and seismic conditions as for Alternative A. The same BMPs described for Alternative A would be implemented for Alternative D. Therefore, under Alternative D, the operational impacts of these components would be similar to those for Alternative A.

4.4.2 Water Resources

4.4.2.1 Affected Environment

The affected environment for water resources in the Alternative D cantonment/family housing project area is described in the 2010 Final EIS Volume 2, Chapter 4: Water Resources, Section 4.1.2.1: Andersen AFB, pages 4-25 to 4-26 and Section 4.1.3.3: Barrigada, pages 4-35 to 4-38). The affected environment for the proposed approximately 11 new wells, school expansions, and off-site utilities common to all cantonment/family housing alternatives would be the same as described under Alternative A in Section 4.1.2.1 of this SEIS.

Surface Water

As indicated in the 2010 Final EIS, surface water resources in the Barrigada cantonment/family housing project area are limited to small man-made ponds within the Nimitz Golf Course and wetlands (see discussion in Wetlands section below). The man-made ponds are not jurisdictional waters of the US. There are no surface water resources in the BEQ/BOQ project area at AAFB, or the utility corridor to AAFB. The Barrigada site averages 95 inches (241 cm) of rainfall annually. With the higher clay content, steep grades, and sizable off-site contributing stormwater basins, this area has the potential to experience
substantial stormwater runoff flows. The general stormwater overland flow direction is from northeast to southwest and ultimately enters the subsurface karst limestone structure through sinkholes and depressions along the western side of the site (Figure 4.4.2-1). Existing impervious areas on the Barrigada project area amount to 13 acres (5 ha), or 1.1% of the proposed Barrigada impacted area of 1,194 acres (483 ha). There are no 100-year flood zones identified within the proposed construction area. 500-year flood zones identified within the proposed construction area are shown in Figure 4.4.2-1.

Groundwater

As indicated in the 2010 Final EIS, the Barrigada project area is underlain primarily by very permeable limestone in the Mangilao and Agaña basins of the NGLA. The utility corridor to AAFB would overlie the Finegayan, Yigo, and Agaña basins of the NGLA and the BEQ/BOQ project area at AAFB would overlie the Andersen Basin of the NGLA. The circumstances concerning the groundwater model developed by the USGS (USGS 2013c) and the current well production are the same as described under Alternative A in Section 4.1.2.1 of this SEIS.

Nearshore Waters

As indicated in the 2010 Final EIS, the Barrigada project area is located inland and does not contain any nearshore waters. The BEQ/BOQ project area on AAFB is located near Tarague Beach and the Pati Point Marine Preserve, which are classified as having M-1 water quality and the use is primarily recreational.

The Barrigada project area would be served by the Agaña WWTP, which discharges into Agaña Bay. As discussed in the 2010 Final EIS (Volume 6, Chapter 6: Water Resources, Section 6.2.4.1: Basic Alternative 1a (Preferred Alternative), pages 6-17 to 6-20), beaches in Agaña Bay are included in GEPA’s impaired water bodies 303(d) list for bacteria and USEPA Region 9 approved a TMDL for beaches in Agaña Bay in March 2010. The TMDL includes a load allocation for bacteria (Enterococci) for the Agaña WWTP that would be imposed under an NPDES permit (USEPA and GEPA 2009). An upgrade to the Agaña WWTP treatment systems is required by the USEPA to support the achievement of the TMDL for bacteria at Tanguisson Beach (Enterococci) and attainment of water quality goals (USEPA and GEPA 2009).

A 2011 Court Order required primary treatment upgrades at the Agaña WWTP. In April 2013, the USEPA issued a new NPDES permit for the Agaña WWTP requiring treatment upgrades at the facility for up to 12 MGd (45 MLd) (USEPA 2013b). The primary treatment upgrades were substantially completed in March 2014. See Section 4.4.14, Utilities in this SEIS for additional details on the Agaña WWTP.

Wetlands

As indicated in the 2010 Final EIS, nine wetlands were identified in surveys conducted in 2010 on or adjacent to the Navy Barrigada and Air Force Barrigada properties. There are no wetlands at the BEQ/BOQ project area on AAFB or along the utility corridor to AAFB. Recent on-site confirmation surveys were conducted on November 7 and December 4-11, 2012 for this SEIS. The on-site confirmation (as well as the 2010 survey) was a non-jurisdictional wetland delineation (delineation being the establishment of wetland boundaries). A jurisdictional delineation establishes the boundaries of wetlands that are subject to requirements in the CWA and its implementing regulations and requires the approval of the USACE.
Figure 4.4.2-1
Water Resources and Wetlands in the Vicinity of Barrigada Cantonment/Housing Alternative D

Sources: WERI 2001; FEMA 2007; USFWS 2010; NAVFAC Pacific 2010, 2013
The 2012 field delineation confirmed the seven wetlands on Air Force Barrigada that were identified in the 2010 surveys. There are a total of 3.2 acres (1.3 ha) for the eight wetlands on Navy Barrigada and Air Force Barrigada (see Figure 4.4.2-1 and Table 4.4.2-1) (NAVFAC Pacific 2010b, 2013a). In addition, there is a 1.1-acre (0.4-ha) wetland on non-federally owned lands between Navy Barrigada and Air Force Barrigada. All of the wetlands are associated with topographic depressions. The wetlands are palustrine emergent wetlands with persistent vegetation (PEM1) that are either seasonally flooded/saturated (PEM1E) or seasonally flooded (PEM1C). The acreage for each wetland is provided in Table 4.4.2-1 and the locations are shown in Figure 4.4.2-1. WetBar-6 contained shallow, seasonally ponded water (water was present in December 2012) (NAVFAC Pacific 2013a). These wetlands are all considered potentially jurisdictional pending a Jurisdictional Determination by the USACE.

### 4.4.2.2 Environmental Consequences

#### Construction

General construction impacts to water resources would be similar to those described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.1: North, pages 4-84 to 4-88) and under Alternative A in Section 4.1.2.2 of this SEIS. Short-term construction impacts associated with the proposed approximately 11 new wells at AAFB, school expansions, and off-site utilities common to all cantonment/family housing alternatives would be the same as described under Alternative A in Section 4.1.2.2 of this SEIS. There would be no impacts to surface water, nearshore waters, and wetlands and less than significant short-term, direct impacts to groundwater for these common elements.

In addition, under Alternative D there would be construction activities associated with the proposed cantonment/family housing at Barrigada, the BEQ/BOQ on AAFB, and the utility corridor to AAFB. Alternative D would occur in an area that contains potentially jurisdictional wetlands, and therefore would be required to comply with the Construction General Permit as described under Alternative A.

Construction under Alternative D would result in the potential for short-term increases in stormwater runoff and erosion. However, through compliance with the Construction General Permit and Program SWPPP and implementation of a site-specific SWPPP and associated erosion control, runoff reduction, and sediment removal BMPs (see Table 4.1.2-2), these short-term effects would be minimized and off-site transport of stormwater runoff would be unlikely unless during extreme weather events (i.e., typhoons). Specifically, the site-specific SWPPP would identify appropriate BMPs for the site that would
serve to contain runoff and sediment on-site by reducing the flow rate of runoff and thereby minimize transport of suspended sediment through settling and promote infiltration of runoff.

**Surface Water**

No buildings/structures would be constructed in the 100-year flood zone. However, some stormwater detention basins could be constructed in the 500-year flood zone and all construction in the 500-year flood zone would be in compliance with EO 11988 as it would not be categorized as a “critical action.” Surface waters within the proposed construction areas under Alternative D are limited to man-made ponds and wetlands (see Wetlands section below for discussion of potential direct impacts to wetlands). Construction would impact the man-made ponds within the Nimitz Golf Course, but these features are not considered jurisdictional waters of the US. Potential indirect effects to wetland areas from stormwater runoff would be minimized by adhering to the provisions of the Construction General Permit and implementing of a Program SWPPP and site-specific SWPPP and associated BMPs that would address site- and activity-specific surface water protection requirements. Therefore, construction activities associated with Alternative D would result in less than significant short-term impacts to surface waters.

**Groundwater**

Construction activities under Alternative D would include stormwater runoff protection measures that would also serve to protect groundwater quality. By adhering to the provisions of the Construction General Permit and implementing BMPs associated with addressing site- and activity-specific water resource protection requirements, there would be a reduction in stormwater pollutant loading potential and thus a reduction in pollution loading potential to the underlying groundwater basins of the NGLA. As described under Alternative A, an environmental and hydrogeologic assessment for the selected alternative would be performed for sinkholes within the project development footprint to ensure adverse effects to groundwater resources would not occur. Direct impacts associated with the induced civilian growth and construction/DoD workforce demand on potable water and the construction of the proposed approximately 11 new wells at AAFB would be the same as described under Alternative A in Section 4.1.2.2 of this SEIS.

Potential increases in the rate of sewage spills associated with the induced civilian growth and construction/DoD workforce would result in significant indirect impacts to groundwater quality as described under Alternative A in Section 4.1.2.2 of this SEIS. Mitigation for these impacts would be the same as described in Section 4.1.2.2 for Alternative A.

Given stormwater runoff protection measures (i.e., compliance with Construction General Permit requirements and implementation of BMPs), the environmental and hydrogeologic assessment for sinkhole protection (if encroachment is unavoidable), siting and construction of wells in accordance with GEPA regulations, minimal increase in water demand or withdrawal from the NGLA during the construction phase, and DoD assistance in identifying funding to upgrade sewer lines, construction activities associated with Alternative D would result in less than significant direct impacts to groundwater.

**Nearshore Waters**

Short-term impacts to nearshore waters from general construction would be similar to those described under Alternative A in Section 4.1.2.2 of this SEIS. The Barrigada cantonment/family housing project area would be located at an elevation ranging from approximately 200 to 400 feet (60 to 120 m) and more than 0.5 mile (0.8 km) from nearshore waters and the BEQ/BOQ project area on AAFB would be located at an approximate elevation of 500 feet (150 m) and 0.7 mile (1.2 km) from nearshore waters. Given
compliance with the Construction General Permit and implementation of a Program SWPPP and site-specific SWPPP and the distance from nearshore waters (i.e., 0.5 mile [0.8 km]), off-site transport of stormwater runoff, sediment, or other pollutants would be unlikely (see discussion of BMPs under Construction) and discharge to nearshore waters would not occur. Therefore, construction activities associated with Alternative D would result in no direct or indirect impacts to nearshore waters from stormwater runoff associated with increased impervious areas.

Induced civilian and construction/DoD workforce growth during construction of the cantonment/family housing facilities under Alternative D would increase demand for wastewater treatment (at the Agaña WWTP for facilities located at Navy Barrigada and at the Northern District WWTP for facilities located at AAFB), and increase requirements for disposal of treated wastewater. As discussed in Section 4.4.14, Utilities in this SEIS, direct and indirect long-term impacts to wastewater from DoD and organic civilian population growth are estimated to increase the maximum monthly wastewater flows to the Northern District WWTP by 2028. Due to the reduced population projection and related smaller increase in demand under the 2012 Roadmap Adjustments, these increases in wastewater discharge from the Agaña WWTP and the Northern District WWTP would be less than under the No-Action Alternative. However, as discussed in Section 4.4.14, Utilities in this SEIS, upgrades to the Agaña WWTP and Northern District WWTP are already needed in order for the plants to achieve compliance with the current NPDES permits. Increasing the wastewater discharge from a non-compliant treatment plant could result in significant indirect impacts to nearshore waters during the period of non-compliance. Potential mitigation to address this significant impact would be similar to that described in the nearshore waters impact discussion for construction of Alternative A in Section 4.1.2.2, but would also include upgrades to Agaña WWTP. Therefore, with the mitigation to upgrade the WWTPs treatment systems, the impact to nearshore waters could be beneficial in the long-term because the total volume of wastewater discharge from the WWTPs would receive a higher level of treatment. However, until the WWTP upgrades are completed there would be an indirect and unmitigable significant impact to nearshore waters during construction.

Wetlands

Implementation of Alternative D could result in direct impacts (fill) to potentially jurisdictional wetland areas in the Barrigada cantonment/family housing project area (see Figure 4.4.2-1). By comparison, there would be no impacts to wetlands under the other proposed cantonment/family housing alternatives. No wetlands are located in or near the construction areas associated with the BEQ/BOQ on AAFB or the utility corridor to AAFB.

Through design and avoidance measures, it is anticipated that most of the wetlands identified in the Barrigada cantonment/family housing project area would be preserved. However, some of the smaller wetlands may be filled if determined to be non-jurisdictional or avoidance would not be possible. Direct impacts (fill) to jurisdictional wetlands would be a significant impact. The wetlands that would potentially be directly impacted at Barrigada include WetBar 7 and a small portion of B-02 (see Figure 4.4.2-1 and Table 4.4.2-1) and amount to 0.1 acre (0.04 ha). If these wetland areas are determined to be jurisdictional by the USACE, and therefore subject to Section 404 (CWA) requirements, the Marine Corps would first attempt to avoid impacts. If avoidance is not possible, then the Marine Corps would obtain a permit from the USACE to fill the wetlands and comply with minimization and mitigation measures outlined in the permit. Unavoidable impacts to jurisdictional wetlands would be mitigated by creating new wetlands, restoring or enhancing existing wetlands, or preserving existing wetland areas on Guam to, at a minimum, replace the area filled. If Alternative D is chosen and wetlands cannot be avoided, the Marine Corps understands that a LEDPA determination must be made as part of the permitting process and that if the
USACE determines this alternative is not the LEDPA, a Section 404 permit under the CWA cannot be granted. Through implementation of the mitigation measures and procedures identified above, significant impacts to wetlands would be reduced to a level below significant.

Potential short-term, indirect effects to other nearby down-gradient wetland areas from stormwater runoff would be less than significant through compliance with the Construction General Permit and implementation of BMPs, as discussed under Surface Water.

**Operation**

Alternative D would incorporate a LID approach in the final planning, design, and construction of the stormwater management system as described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.1: North, pages 4-85 to 4-87) and under Alternative A in Section 4.1.2.2 of this SEIS. Operational impacts associated with the proposed approximately 11 new wells at AAFB, school expansions, and off-site utilities common to all cantonment/family housing alternatives would be the same as described under Alternative A in Section 4.1.2.2 of this SEIS. There would be no direct or indirect impacts to surface water, nearshore waters, and wetlands and less than significant long-term impacts to groundwater for these common elements.

The proposed stormwater management system infrastructure improvements included as part of the proposed action would incorporate LID measures and BMPs for compliance with local and federal requirements that are designed to minimize potential long-term, indirect impacts to downstream development, sensitive water resources, and ecology, as described under Alternative A in Section 4.1.2.2 of this SEIS. Alternative D would be implemented in accordance with all applicable orders, laws, and regulations including the preparation and implementation of a SWPPP, SWMP, and SPCC plan that would control runoff and minimize potential leaks and spills.

Under Alternative D, the total impervious area on the Barrigada project area would increase by 319 acres (129 ha). This increase from 1.1% to 28% impervious area, for a total of 332 acres (134 ha), would result in an associated increase in stormwater runoff volume for each of the design storm events. The utility corridor to AAFB would result in minimal increase in impervious area. Alternative D would result in increased runoff of 446 acre-feet (550,000 m³) and 708 acre-feet (873,400 m³) from the 25-year and 100-year design storms, respectively. However, the project design would include vegetated swales for conveyance and treatment and detention/retention ponds capable of capturing, storing, and treating additional runoff from the 25-year design storm (see Appendix F for examples of LID applications that would be used and conceptual design of stormwater runoff routing and pond locations). As part of the planning design, the project area was delineated into sub-basins with stormwater conveyance systems to route discharges to appropriately sized detention basins. For each sub-basin, water quality treatment strategies were selected based on the effectiveness of BMPs to treat identified pollutants of concern from proposed land uses within that sub-basin. The selected water quality treatment strategies would achieve reductions of non-point source pollutants to meet the same water quality requirements as identified under Alternative A in Section 4.1.2.2 of this SEIS. In addition, DON would develop and implement a “LID BMP O&M Inspection Checklist” consistent with the 2006 CNMI Guam Stormwater Management Manual to monitor and ensure the effectiveness of LID features during operation. Any deficiencies would be reported to and addressed by the future Public Works Department of the Marine Corps Base Guam.

The final Grading/Drainage/LID Study, dated July 2013, would be provided to the design team for guidance and implementation during design and construction. The designs performed by these contractors would be subject to review by DoD professionals and technical consultants to ensure proper implementation both during design and verification during construction.
Surface Water

Surface waters within the proposed construction areas under Alternative D are limited to wetlands (see Wetlands section below for discussion of wetlands). Potential indirect effects to wetland areas from stormwater runoff would be minimized through implementation of an appropriate and comprehensive stormwater management plan utilizing a LID approach and other stormwater runoff protection measures and there would be no increase in off-site transport of excess stormwater runoff, sediment, or other pollutants for up to the 25-year design storm event. Therefore, operations associated with Alternative D would result in less than significant long-term, indirect impacts to surface waters.

Groundwater

Under Alternative D, proposed operations would be in compliance with the stormwater runoff protection measures identified above that would also serve to protect groundwater quality and recharge. Specifically, implementation of LID measures and the provisions of the SWPPP and associated erosion control activities would ensure that the stormwater runoff flowing into infiltration basins and recharging the aquifer would be of acceptable quality.

There would be substantially less removal of primary and secondary limestone forest, as compared to Alternative A (i.e., approximately 170 acres [70 ha] for Alternative D vs. 1,000 acres [400 ha] for Alternative A), but more area would be converted to impervious area (i.e., approximately 319 acres [129 ha] for Alternative D vs. 273 acres [110 ha] for Alternative A). Similar to Alternative A, these changes in land cover and impervious area under Alternative D would also result in minor changes to groundwater recharge rates. However, these changes in land cover and impervious area were accounted for during the development of a conceptual level of design for grading, drainage, and LID measures, and projected changes in recharge rates would be managed through updating the USGS numerical groundwater model to determine modifications to groundwater pumping, as described under Alternative A. Increased groundwater withdrawal would also be the same as described under Alternative A in Section 4.1.2.2 of this SEIS. There would be short-term, localized significant impacts to the affected basin within the NGLA but less than significant impacts to the overall NGLA. Potential mitigations would be the same as described for Alternative A in Section 4.1.2.2 of this SEIS.

Given stormwater runoff protection measures (i.e., implementation of LID and pollution prevention plans); implementation of water conservation measures; groundwater demand from the NGLA that would be substantially less than the sustainable yield; improved management of the NGLA through use of the numerical groundwater model; DoD assistance in identifying funding through the EAC process for an updated and expanded monitoring network; and other potential mitigation measures discussed above, operations associated with Alternative D would result in less than significant impacts to the overall NGLA and short-term, localized significant but mitigable impacts to the affected basin within the NGLA.

Nearshore Waters

Under Alternative D, proposed operations would be in compliance with the stormwater runoff protection measures identified above that would ensure that there would be no increase in off-site transport of stormwater runoff, sediment, or other pollutants for up to the 25-year design storm event. In addition, the distance of the project area from nearshore waters (i.e., 0.5 mile [0.8 km]) would ensure stormwater runoff, sediment, or other pollutants would not discharge to nearshore waters. Therefore, there would be no impacts to nearshore waters from stormwater runoff associated with increased impervious areas under Alternative D.
Water resources would be impacted by the increased wastewater discharge from the Northern District WWTP and Agaña WWTP during the operation of cantonment/family housing under Alternative D. The associated potential impacts would be similar to those described above in the discussion of Alternative D construction impacts to nearshore waters. However, upgrades to bring the Northern District WWTP and Agaña WWTP into compliance with the permits are expected to be completed early in the operational phase of the proposed action and such upgrades would mitigate the impact to a less than significant level. Refer to construction impacts above for a detailed discussion of WWTP discharge impacts and mitigation.

**Wetlands**

Under Alternative D, proposed operations at Barrigada have the potential to cause indirect effects to nearby down-gradient wetland areas, as several of the wetland areas would receive stormwater runoff/overflow from the adjacent proposed detention/retention ponds during certain storm events. However, the stormwater runoff protection measures identified above would also protect water quality entering wetlands. Specifically, implementation of LID measures and the provisions of the SWPPP and associated erosion control activities would ensure that the stormwater runoff flowing into wetlands would be of acceptable quality. Given stormwater runoff protection measures (i.e., implementation of LID and pollution prevention plans), operations associated with Alternative D would result in less than significant indirect, long-term impacts to wetlands.

**4.4.3 Air Quality**

**4.4.3.1 Affected Environment**

Ambient air quality conditions around Barrigada are affected primarily by mobile source emissions associated with the military operations at the base and aircraft operations at Guam International Airport. Highway traffic along Routes 8, 10, 15, and 18 also contribute mobile source emissions in the area. Sensitive populations near the site are mostly located along major traffic routes.

**4.4.3.2 Environmental Consequences**

**Construction**

The construction phase annual emissions were predicted for Alternative D and are summarized in Table 4.4.3-1. Annual direct emissions would be well below the significance criterion of 250 tpy, as shown in Table 4.4.3-1. The CO₂ emissions during construction period would be less than those analyzed in the 2010 Final EIS resulting in less GHG impacts as compared to the No-Action Alternative.

Legend: SO₂ = sulfur dioxide; CO = carbon monoxide; PM₁₀ = particulate matter (<10 microns); PM₂₅ = particulate matter (<2.5 microns); NOₓ = nitrogen oxides; VOC = volatile organic compounds; CO₂ = carbon dioxide; neg = negligible.
Under Alternative D, the maximum on-site annual PM emission levels predicted and summarized in Table 4.3.1-1 are slightly less than under Alternative A (see Table 4.1.3-2) (i.e., 2.5 tpy as compared to 2.8 tpy for PM$_{10}$ under Alternative A). Therefore, the on-site hot-spot short-term PM impacts around construction sites would be less than or similar to those under Alternative A as shown in Table 4.1.3-3.

**Off-Site On-Road Vehicle Hot-Spot Analysis for CO, PM, and MSATs**

Off-site on-road vehicle CO, PM, and MSATs hot-spot impact concentrations for Alternative D would be similar to those predicted for Alternative A (Section 4.1.3.2) at the analyzed intersections. This comparison is based on review of similar truck routes, as well as level of truck volumes anticipated during the construction period, under both this alternative and Alternative A. Since the concentration levels predicted under Alternative A, shown in Tables 4.1.3-3 and 4.1.3-4, for PM and CO are well below their respective NAAQS; the hot-spot concentration levels under Alternative D, similar to Alternative A, would be well below the NAAQS, resulting in less than significant short-term PM and CO impacts.

For the same above reason, off-site on-road vehicle MSATs concentration levels would be similar to those predicted under Alternative A, as shown in Tables 4.1.3-6 and 4.1.3-7, with the comparison of cancer and non-cancer risks. Therefore, the project impacts of all carcinogenic and non-carcinogenic MSATs are considered acceptable. Based on these findings, short-term construction phase air quality impacts under Alternative D are considered less than significant.

**Operation**

As explained in Section 3.3.3; during operational years, Alternative D would result in the worst-case off-site on-road vehicle miles travelled and would, therefore, generate the worst-case vehicular emissions. The hot-spot impact analyses of off-site on-road vehicle CO, PM, and MSATs emissions during operational years were conducted using the same methods described for Alternative A (Section 4.1.3).

**Off-Site On-Road Vehicle Hot-Spot Analysis for PM**

As described in Section 4.1.3 and shown in Table 4.1.3-5, the future worst-case construction year annual average daily traffic of the roadways within the study area are well below the USEPA defined screening threshold of 125,000 annual average daily traffic and 8% diesel truck traffic, which equates to 10,000 trucks. Therefore, a further hot-spot dispersion modeling analysis is not warranted and there would be no PM hot-spot concerns along the affected roadway network.

**Off-Site On-Road Vehicle Hot-Spot Analysis for CO**

Table 4.4.3-2 shows the total concentrations for CO in comparison to the respective NAAQS. The predicted levels are well below the NAAQS, resulting in less than significant long-term CO impacts.

Off-Site On-Road Vehicle Hot-Spot Analysis for MSATs

MSATs concentration levels predicted under Alternative D are shown in Table 4.4.3-3. Maximum estimated increases in cancer risk at any of the receptors due to the project are all less than the threshold criterion of 10 in a million. Therefore, the direct, long-term project impacts of all carcinogenic MSATs are considered acceptable.

The maximum chronic hazard index at any of the receptors due to project emissions are well below the target limit of 1, as shown in Table 4.4.3-4. Therefore, the direct, long-term project impacts of all non-carcinogenic MSATs are considered acceptable.

4.4.4 Noise

4.4.4.1 Affected Environment

Barrigada is located in an area where aircraft operating out of either AAFB or Guam International Airport generate noise contours below 60 dB and are not a factor for baseline conditions. Traffic noise along Routes 8, 10, 15, and 16 dominates the noise environment near Barrigada. Available noise data near Barrigada were collected at 156 Adacao (near the intersection of Route 8 and 10A) and 101 Route 16 with long-term noise levels of 64 dB and 65 dB, respectively.

4.4.4.2 Environmental Consequences

Construction

Construction of the cantonment area would occur in the southwest portion of federally owned lands at Barrigada. Off-base frontage would be Route 15 to the south and would provide access to Barrigada with a commercial gate and the main gate. Bachelor’s quarters and parking, the commercial and main gates, open space, and an area reserved for future development would be located on-base. From south to north along the west side of Barrigada would be the commercial gate and associated structures, a collector road and operations.

Family housing would be located in the northern part of Barrigada and the closest house would be set back several hundred feet from the northern boundary line. Construction noise impacts would be primarily due to development of the cantonment area along the western boundary.

Approximately 25 residences are located adjacent to the boundary along the west side of Barrigada and about 14 residences along Route 15 with 92 and 51 people, respectively (based on average household size estimates for Guam). The construction area closest to off-base receptors would be the cantonment operations area and would be approximately 150 feet (46 m) to 200 feet (61 m) from construction activities. As discussed in Section 4.3.4, 10 pieces of heavy machinery operating simultaneously this close to a receptor is virtually impossible from a spatial point of view. Similar to Alternative C construction assumptions, it is assumed that five pieces of heavy equipment operating at 150 feet (46 m) and five operating at 200 feet (61 m) would be used. Under this scenario, short-term noise levels would be at 74.8 dBA $L_{eq}$ just below the USEPA threshold guideline of 75 dBA $L_{eq}$. However, similar to all cantonment/family housing alternatives, the construction schedule for these Roadmap Adjustments would be spread out. Sequencing work tasks and allowing only one or two pieces of heavy equipment operating in areas close to the nearest receptors would lessen the noise impacts. If only the two loudest pieces of equipment, a grader and a scraper, operated at 150 feet (46 m) and 200 feet (61 m) respectively, noise levels would be 69.4 dBA $L_{eq}$. Approximately 25 homes housing about 92 people would be affected by the cantonment construction. As cantonment/family housing construction noise would be below the 75 dBA USEPA construction threshold guideline, short-term noise impacts would be less than significant.

Long-term construction noise impacts consider noise generated throughout the entire duration of construction. Under this alternative, the following three different locations are analyzed: from a residential perspective; from the center of the cantonment area; and from the center of the family housing area. The cantonment area would be spread out more under this alternative compared to Alternatives A, B, and C. From the perspective of an individual receptor along the western and southern boundary of Barrigada, noise levels above 65 dB would be considered incompatible for long-term land-use noise exposure. Given the equipment list previously estimated in Alternative A, construction would need to be with 525 feet (160 m) to generate noise levels above the 65 dBA FICUN. This level is also considered the limit for annoyance. This distance comprises an insignificant percentage (<1%) of the total construction
area and should actually be considered short-term noise exposure because could not possibly last at that level for the entire 10-year period. Therefore, from this perspective, long-term noise from construction within the 525 foot (160 m) zone would be less than significant.

The cantonment area closest to receptors would be located approximately 1,000 feet (305 m) from the western edge of the Barrigada boundary. Long-term noise from of the cantonment facilities would generate noise levels of approximately 62.4 dBA. Therefore, long-term noise levels due to cantonment construction would be less than significant.

The center of the family housing would be approximately 2,000 feet (610 m) from the northern boundary of Barrigada and long-term noise levels would be about 56 dBA and well less than the FICUN criteria. Consequently, short-term and long-term construction noise impacts would be less than significant for Alternative D.

Construction activities common to all alternatives include off-site utilities and school expansions. Impacts due to these common construction projects would be as described in Section 4.1.4.2.

Operation

Upon full build-up after construction has been completed, the steady-state noise generating activities at Barrigada would be primarily due to traffic noise. Traffic noise around Barrigada would be near the proposed Main Gate on Route 15 and the Residential Gate on Route 16. The noise experienced by most noise receptors identified in the 2010 Final EIS (Volume 6, Chapter 8: Noise, Section 8.6.6.2, pages 8-49 to 8-51) affected by noise levels above 66 dB could be reduced to below 66 dB and compliant with the GDPW transportation standards because there would be nearly 50% reduction in traffic increases compared to the traffic levels described in the 2010 Final EIS. Potential noise mitigation improvement, such as sound walls, would be constructed in accordance with measures described in the 2010 Final EIS, reducing noise impacts in areas that are reasonable and technically feasible. Consequently, noise impacts due to cantonment/family housing operations and traffic at Barrigada would be less than significant.

4.4.5 Airspace

4.4.5.1 Affected Environment

Operations and functions under Alternative D consist of support, maintenance/storage, housing, and non-live fire training functions (see Section 2.2.1 in Chapter 2 of this SEIS). There would be no construction or operation activities requiring changes to airspace. Therefore, the affected environment for airspace is only discussed in the context of the LFTRC components of the proposed action (see Chapter 5).

4.4.5.2 Environmental Consequences

As discussed above, there would be no construction or operation activities requiring changes to airspace. Therefore, there would be no impact on airspace from this component of the proposed action.
4.4.6 Land and Submerged Land Use

4.4.6.1 Affected Environment

The affected environment for land use under Alternative D is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 8: Land and Submerged Land Use, Section 8.1.3.2: Affected Environment, pages 8-34 to 8-35), and is summarized below for reference. The closure of the Nimitz Golf Course is the primary change in the affected environment subsequent to the 2010 Final EIS.

Figure 4.4.6-1 shows the land use associated with the Barrigada area and the surrounding land use classifications on an aerial image. Barrigada is federally owned and there are no submerged lands associated with it.

In summary, the DON uses the northern portion of Barrigada as a high frequency transmitter station. The transmitters generate an EMR arc that extends into the community. Guam Army National Guard also has facilities in this northern area near the site entrance off Route 8. An Army Reserve Battalion headquarters building is adjacent to the Guam Army National Guard facilities. Urban warfare training occurs in abandoned buildings. In addition, there are water wells and associated clearance zones (Figure 4.4.6-1).

The southern portion of Barrigada has a Next Generations Radar weather antenna in the center. The narrow strip of land connecting the northern and southern portions of Barrigada was the former Nimitz Golf Course (Figure 4.4.6-1), but the facilities are no longer in use.

The Barrigada area is generally bordered by residential neighborhoods and vacant (i.e., no modern manmade structures) land. Guam International Airport (i.e., A.B. Won Pat International Airport) is northwest, but not adjacent to the parcel. The land use plan designation for the adjacent surrounding land is Very Low Density Residential or Residential, except for an area of Commercial use at the northwest corner of Barrigada and a small area of Village Center at the northeast (Figure 4.4.6-1).

4.4.6.2 Environmental Consequences

The land use impacts are addressed in this section. Land ownership impacts are addressed in Section 4.4.15, Socioeconomics and General Services.

Construction

As previously discussed in Section 3.6.3.1, Methodology, all changes in land use are considered long-term operational impacts. Therefore, there is no construction-phase analysis for this resource under any of the alternatives.

Operation

All cantonment alternatives require water well development on AAFB. The affected environment and environmental consequences are described in Section 4.3.6. The proposed expansion of existing education facilities and the off-base utilities common to all alternatives are as described under Section 4.1.6. The off-base utility improvements specific to this alternative are aligned along Routes 3, 8 and 16. No land acquisition would be required for the utilities. No land use impacts would be associated with the education. However, additional inter-base IT/COMM connectivity would be required as described in Chapter 2. This includes the connection between AAFB and the existing Tata cable landing facility in southern Guam, which would require new rights of way along some southern roads and the access road to the Tata facility.

Ballfield

Sources: DON 2010, NAVFAC Pacific 2013
The proposed development would not impact submerged lands.

The proposed development would be compatible with existing mission critical uses and land use constraints. However, the antenna maintenance facility would be relocated. There would be a loss of open space and an increase in development density throughout Barrigada. The maximum height of the cantonment buildings would be six stories and the housing would be a maximum of two stories. Open space is incorporated in the design but there would be less open space than currently exists at the parcel, resulting in a less than significant long-term impact on the community adjacent to the base.

Eagle Field, a sports field currently accessible and used by the public, is located at the southern end of the Barrigada site near Route 15. The use of this field would be precluded by Alternative D; however, the ballfield is on DoD land, is not a unique resource, and the access is periodically renegotiated; however, there are impacts to recreational resources, as described in Section 4.4.7.

The proposed cantonment is compatible with adjacent off-base existing residential and industrial (Guam International Airport) land uses to the north and west of Barrigada. The proposed family housing would be compatible with the planned residential and very low density areas adjacent to the former golf course and southern portion of Barrigada (Figure 4.4.6-1).

Since Alternative D does not have any significant impacts to land use resources, it would have less of an impact than Alternative B.

4.4.7 Recreational Resources

4.4.7.1 Affected Environment

The primary recreational resource at Alternative D was the Nimitz Golf Course, a championship 18-hole golf course that closed permanently in January 2013 (see 2010 Final EIS Volume 2, Chapter 9: Recreational Resources, Section 9.1.3.2: Affected Environment, pages 9-6 and 9-8). Nimitz Golf Course was open to both military members and civilians and occupied the Navy Barrigada portion of the Barrigada site. Eagle Field, a sports field currently accessible and used by the public, is located at the southern end of the Barrigada site near Route 15. There is currently a formalized agreement between the Air Force and the Mayor of Mangilao for use of this field by the public. As of October 2013, the Air Force and the Mayor of Mangilao are in the process of renewing this agreement, so execution of this renewal has not yet occurred.

4.4.7.2 Environmental Consequences

Construction

With regard to construction activities, the short-term increase of construction-related vehicles on roads may cause delays to persons accessing recreational areas. Although staged construction equipment would not obstruct access to and the use of the recreational resources, inconvenience to resource seekers (e.g., potential direct impacts from detours, longer waits, and other similar nuisances) would result. Therefore, less than significant short-term impacts to recreational resources would be anticipated.

Operation

Overall recreational resource impacts would be less than those anticipated in the 2010 Final EIS due to the significantly reduced number of Marines and dependents coming to Guam. The Eagle Field would be removed as part of the base development under Alternative D and the public would no longer have access to this facility. Currently, the intensity and frequency of use at this sports field has not been verified but appears to be used quite frequently by the public for football and softball games, as well as festivals. This
9.2-acre (3.7 ha) site is easily accessible from Route 15 and Route 10 and is centrally located on the island near population centers. However, the field is located on federal property and is not formally recognized as a part of the Guam park system. Based on aerial maps of the area and a review of the 2006 Guam Comprehensive Outdoor Recreation Plan Update, there is a GDPR sports playing field located approximately 0.25 mile (0.4 km) to the west of the Barrigada site, as well as numerous playing fields near the Mangilao Community Center at the southeast corner of the intersection of Route 15 and Route 10, less than 1 mile (1.6 km) from the Barrigada site. These alternate sports field locations are in close proximity. However, the direct impacts from removal of Eagle Field from public use could result in a long-term significant impact to recreational resources in central Guam because Eagle Field is a primary location for youth and adult sports programs. Potential mitigation measures have not been identified at this time.

4.4.8 Terrestrial Biological Resources

4.4.8.1 Affected Environment

See Section 4.1.8.1 for a description of the affected environment for the AAFB support areas. The following is a discussion of only Barrigada.

Vegetation Communities

Based on 2012 surveys conducted on Barrigada, the mapped vegetation communities on portions of Barrigada was modified from the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.4.3: Navy Barrigada and Air Force Barrigada, page 10-59) (NAVFAC Pacific 2013a). In the portion of northern Barrigada surveyed in 2012, limestone forest was remapped as secondary limestone forest based on the degraded conditions of the forest documented during the survey (Figure 4.4.8-1). In southern Barrigada, large plots of land were characterized in the 2010 Final EIS as developed because of the presence of agricultural fields and other open areas and to correspond with USFS (2006) mapping. However, 2012 surveys found that most of these areas were no longer being used and scrub and other weedy vegetation was predominant. Therefore, these areas were remapped as mixed herbaceous-scrub (NAVFAC Pacific 2013a).

Terrestrial Conservation Areas

The Barrigada area does not contain any designated terrestrial conservation areas.

Wildlife - Native Species

Use of forested or grassland at Barrigada by native bird species is minimal, as described in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.4.3: Navy Barrigada and Air Force Barrigada, page 10-59). During surveys in December 2012, several migratory birds were seen using a small ephemeral pond with open water along the southwestern border: yellow bittern, little egret, and black-winged stilt. Native reptiles observed in 2012 field studies were blue-tailed skink and mourning gecko (NAVFAC Pacific 2013a).

During 2012 field surveys, non-native feral pigs were heard and heavy damage was observed in the north-central and southern forested areas of Barrigada (NAVFAC Pacific 2013a). The small wetlands present within the southwestern border of Barrigada had light to moderate feral pig damage. Additional information regarding non-native wildlife species at Barrigada is provided in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.4.3: Navy Barrigada and Air Force Barrigada, page 10-59).

Special-Status Species: Federal ESA-Listed and Proposed Species

One federal ESA-listed species (Mariana common moorhen) occurs at Barrigada (Table 4.4.8-1 and Figure 4.4.8-1). Although “suitable habitat” for special-status species is present within the Alternative D project areas, the brown treesnake, the primary factor in the extirpation of special-status wildlife species on Guam and one of the largest obstacles to achieving recovery of special-status species, is still considered abundant and widespread on Guam. Until brown treesnakes are suppressed or removed from at least targeted areas on Guam, the habitat is not in a suitable condition to support the survival of special-status species due to current snake abundance on Guam (e.g., Guam Micronesian kingfisher, Guam rail, Mariana crow) (USFWS 2010a).

Legend: *Bar = Barrigada, E = endangered, NR = not reported, PE = proposed endangered, PT = proposed threatened, T = threatened. †Occurrence within Barrigada, Support Areas (south-central AAFB and Adjacent), or BEQ/BOQ Housing at AAFB.

A summary for each species is provided below. Utility corridors and other support areas required for this Alternative D are the same as required for Alternative 1 described in Section 4.1.8.

Mariana Fruit Bat. Mariana fruit bat population estimates on Guam in 2006 indicated fewer than 100 individuals (Janeke 2006). In 2009, the number of fruit bats on Guam was estimated to be less than 50 individuals (USFWS 2009a). Extensive surveys conducted throughout AAFB between December 2010 and December 2011 resulted in a conservative estimate of approximately 25 fruit bats (JRM et al. 2012a). Only 50 detections of individual bats were recorded during 84 station count surveys from March through September 2012, and no active fruit bat aggregation or colony site was discovered (JRM et al. 2012b). It is likely that a small number of solitary-roosting fruit bats (<10) also occur on Navy lands. Solitary individuals can move to and from areas during the year. The majority of fruit bats remaining on Guam likely reside on AAFB.

Recent fruit bat observations were of single flying individuals and (in a few cases) roosting and were most commonly observed in three general regions on AAFB as shown in Figure 4.1.8-5: the cliffline extending from above the CATM Range east to Pati Point; in or near the MSA; and in the vicinity of the HMU (USGS brown treesnake research enclosure) (JRM et al. 2012a). High and medium priority fruit bat roosting habitat as defined in the AAFB Mariana Fruit Bat Management Plan are depicted in Figure 4.1.8-5. These areas are based on the location of historic colony roost locations on AAFB and current habitat conditions (AAFB 2008b). Fruit bats do occur within the proposed utility support areas associated with Alternative D (see Figure 4.1.8-5).

As reported in the 2010 Final EIS, daytime sightings of bats (in solitary and in small groups) were made during 1980-1999 in the Barrigada Area at Mt. Barrigada and near the Nimitz Golf Course (Personal Communication via email regarding historical locations of fruit bats on Guam from J. Quitugua, Biologist, GDAWR to G. Metzler, TEC Inc., September 21, 2009). There have been no observations of fruit bats at Barrigada since 1999. The closest known occurrence of fruit bats is on AAFB, more than 8 miles (13 km) to the north of Barrigada. While fruit bats are known to travel 6-7.5 miles (10-12 km) to reach forage areas (USFWS 1990), given the disturbed nature of the area on and surrounding Barrigada and the estimated very low numbers of fruit bats currently on Guam that are found only within AAFB and NAVMAG (13 miles [21 km] to the south), it is unlikely that fruit bats would occur within the Barrigada action area. However, fruit bat recovery habitat is found within proposed project impacted areas in support areas on AAFB and adjacent lands (see Figure 3.8.3-1). Therefore, this species is addressed only for the proposed support areas on AAFB associated with Alternative D.

Mariana Common Moorhen. Mariana common moorhens have been reported in a man-made pond at the Nimitz Golf Course (now closed) on Barrigada (see Figure 4.4.8-1) (COMNAV Marianas 2001). Although field surveys in 2012 did not include the Nimitz Golf Course, the surveys did document the presence of seven small, depressional wetlands in southern Barrigada (NAVFAC Pacific 2013b). All but one of these wetlands had either no open water or only very small pools of water along some of the low-lying margins. One wetland along the southwestern border did have a significant area of open water when visited on December 6, but by a second visit on December 17 the water had substantially receded and would likely have been dry within a few weeks (NAVFAC Pacific 2013a). Based on communications with USDA Wildlife Services, this pond is most likely man-made and the result of a proposed construction project at Barrigada that was halted over 10 years ago. It is unknown if the pond contains a substantial area of open water in all years or only in particularly wet years such as occurred in 2012. This seasonal pond could be marginal temporary habitat for the Mariana common moorhen.

The Mariana common moorhen has not been reported from AAFB (JRM 2013).
Mariana Crow. Since 2009, the Mariana crow population on Guam consisted only of two males on AAFB, occurring primarily within the MSA (USFWS 2009c). However, as of 2012, the Mariana crow is considered extirpated in the wild on Guam (Personal communication via letter from USFWS, Pacific Islands Fish and Wildlife Office, Honolulu, HI regarding the DON NOI for Proposed Placement of LFTRC on Guam NWR; December 7, 2012). The closest population of crows is on the island of Rota, approximately 56 miles (90 km) north of Guam. Therefore, as the crow does not occur in the wild on Guam, there would be no impacts to the crow at Barrigada with implementation of Alternative D. However, crow recovery habitat is found within proposed project impacted areas in support areas on AAFB and adjacent lands (see Figure 3.8.3-1). Therefore, this species is addressed only for the proposed support areas on AAFB associated with Alternative D.

Guam Rail. The Guam rail has been extirpated in the wild on Guam since 1985 and exists primarily in captivity on Guam and in mainland zoos. Experimental populations of Guam rails were introduced onto Rota, CNMI in 1989 and onto Cocos Island, off the southern coast of Guam, in 2011 (USFWS 2009b; BirdLife International 2013). The Guam rail prefers edge habitats, especially grassy or secondary vegetation areas which provide good cover; mature forest is deemed only marginal for the Guam rail (USFWS 2009b). Rail recovery habitat within the proposed impacted areas associated with Alternative D includes secondary limestone forest, herbaceous scrub, and tangantangan (see Figure 3.8.3-2).

Guam Micronesian Kingfisher. The Guam Micronesian kingfisher was extirpated in the wild by 1988 and is now found only in captivity on Guam and at mainland zoos (USFWS 2008). Kingfishers utilized a wide variety of habitats including primary and secondary limestone forest, strand forest, coconut forest, edge habitats, and forest openings, but mature forests with tree cavities suitable for nesting may be an important requirement for kingfisher reproduction (USFWS 2008). Therefore, as the kingfisher does not occur in the wild on Guam, there would be no impacts to the kingfisher at Barrigada with implementation of Alternative D. However, kingfisher recovery habitat is found within proposed project impacted areas in support areas on AAFB and adjacent lands (see Figure 3.8.3-1). Therefore, this species is addressed only for the proposed support areas on AAFB associated with Alternative D.

Slevin’s Skink. Originally found on Guam, Cocos Island, Rota, Tinian, Guguan, Alamagan, Asuncion, and Maug, it is now limited to Cocos Island, Sarigan, Guguan, Alamagan, Pagan, and Asuncion. Slevin’s skink has not been recorded on Guam since 1945 and is believed to be extirpated from Guam; it is now known to occur only on Cocos Island (an atoll south of Guam) (USFWS 2014a). There are no records of the species within the impacted areas of Barrigada or AAFB (USFWS 2014b). Therefore, as Slevin’s skink is not found within the impacted areas of Alternative D, this species is not addressed further.

Tree Snails. As described in Section 10.1.4.3 of the 2010 Final EIS, the ESA proposed endangered Guam tree snail was observed at one location in secondary limestone forest in the north-central portion of Barrigada during vegetation surveys in 2008 (see Figure 4.4.8-1) (NAVFAC Pacific 2010). Surveys conducted in 2013 at Barrigada along four transects totaling 7,150 feet (2,180 m) within limestone forest did not observe any of the proposed endangered tree snail species. No tree snails have been recently recorded from the impacted areas associated with Alternative D (UoG 2014). Therefore, as tree snails are not found within the impacted areas of Alternative D, these species are not addressed further.

Mariana Wandering Butterfly. The ESA-proposed species Mariana wandering butterfly has not been seen on Guam since 1979 and considered extirpated; a single remaining population occurs on Rota, CNMI (USFWS 2013). The only species known to be a Mariana wandering butterfly host plant (Maytenus thompsonii) is a common shrub of limestone forests on Guam and was observed during 2013.
surveys within the impacted areas associated with Alternative D (see Figure 4.1.8-4) (Moore and McMakin 2001; UoG 2014).

**SERIANTHES** Tree. There are no records of the species within the impacted areas associated with Alternative D (USFWS 2014b). However, *Serianthes* recovery habitat is found within proposed project impacted areas in support areas on AAFB and adjacent lands (see Figure 3.8.3-2).

**HERITIERA LONGIPETIOLATA.** This endemic tree is found on AAFB in crevices of rough limestone in primary limestone forest. A 2007 study documented the species as occurring at numerous locations on AAFB, primarily in the central portion of the base, and near the limestone cliffs in the northeast and southeast corners (UoG 2007) (see Figure 4.1.8-5). There is one historical record of an individual within the northern portion of Barrigada (USFWS 2014a, 2014b); however, this species was not observed during surveys in 2010 and 2012 (NAVFAC Pacific 2010, 2013a, 2013b). Therefore, as *H. longipetiolata* is not found within the impacted areas of Alternative D, this species is not addressed further.

**TABERNAMONTANA ROTENSIS.** There are no records of *T. rotensis* within the Alternative D impacted areas. The distribution of this tree species on AAFB was evaluated in 2007 and over 21,000 *T. rotensis* individuals were found throughout AAFB at 265 mapped locations, primarily in the central portion of the base and near the limestone cliffs in the northeast (see Figure 4.1.8-2) (UoG 2007). A few individuals have been recorded within the proposed utility support areas in south-central AAFB (see Figure 4.1.8-2). Therefore, as *T. rotensis* is not found within the impacted areas of Alternative D, this species is not addressed further.

**CYCAS MICRONESICA.** The cycad is found in limestone forests throughout Guam, including AAFB, and is proposed as an endangered species under the ESA because of the Asian cycad scale insect that is devastating the species (USFWS 2014a). This species has not been observed within the Alternative D impacted areas associated with the cantonment/family housing alternatives during past surveys (AAFB 2008b; NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014b). Therefore, as *C. micronesica* is not found within the impacted areas of Alternative D, this species is not addressed further.

**BULBOPHYLLUM GUAMENSE.** An epiphyte in the orchid family, this species occurs in mat-like formations on tree branches of coastal lowland/limestone forests. Currently, there are 8 known occurrences on Guam totaling fewer than 250 individuals (USFWS 2014a, 2014b). Although there is a record of this species immediately to the north of the proposed Alternative D impacted area (see Figure 4.4.8-1), there are no records of the species within the impacted area (USFWS 2014b). Therefore, as *B. guamense* is not found within the impacted areas of Alternative D, this species is not addressed further.

**DENDROBIUM GUAMENSE.** An epiphyte in the orchid family, this species occurs on tree branches of coastal lowland/limestone forests. Currently, there are 4 known occurrences on Guam with fewer than 250 individuals (USFWS 2014a, 2014b). There are no records of the species within the impacted areas of Barrigada or AAFB support areas (USFWS 2014b). Therefore, as *D. guamense* is not found within the impacted areas of Alternative D, this species is not addressed further.

**EUGENIA BRYANII.** A perennial shrub in the myrtle family, the species is known only from the island of Guam. Historically, *E. bryanii* is known from windy exposed coastal clifflines and along the Pigua River, in lowland/limestone forests. Currently, *E. bryanii* is known from 6 occurrences totaling fewer than 420 individuals (USFWS 2014a, 2014b). Only one occurrence is within the vicinity of the proposed project areas – one individual plant was observed in July 2014 to the west of the southern end of the AAFB flightline (Figure 4.1.8-5) (Personal communication from J. Farley, NAVFAC Marianas, to R. Spaulding, Cardno, regarding *Eugenia bryanii* observation at AAFB, 29 October 2014). There are no records of the
species within the impacted areas of Alternative D (USFWS 2014b). Therefore, as *E. bryanii* is not found within the impacted areas of Alternative D, this species is not addressed further.

**MAESA WALKERI.** A shrub or small tree in the primrose family typically found in limestone forests, this species is known from only 2 individuals on Guam – 1 individual on Mt. Lamlam and 1 individual on Mt. Almagosa (USFWS 2014a, 2014b). There are no records of the species within the impacted areas of Alternative D (USFWS 2014b). Therefore, as *M. walkeri* is not found within the impacted areas of Alternative D, this species is not addressed further.

**NERVILIA JACKSONIAE.** A small herb in the orchid family, this species is found in lowland/limestone forests. On Guam, *N. jacksoniae* is known from 2 occurrences totaling fewer than 200 individuals: 1 is near the UoG campus and 1 is to the northwest of Tarague Beach (USFWS 2014a, 2014b). There are no records of the species within the impacted areas of Alternative D (USFWS 2014b). Therefore, as *N. jacksoniae* is not found within the impacted areas of Alternative D, this species is not addressed further.

**SYCHOTRIA MALASPINAE.** A shrub or small tree in the coffee family, this species is found in lowland/limestone forests. Currently, *P. malaspinae* is known from 5 occurrences: 1 individual at Ritidian Point within the Guam NWR, 1 individual at Pågat Point, 1 individual at the base of Mt. Almagosa, and 2 individuals at NWF (USFWS 2014a, 2014b). None of these individuals have been observed within the last 5 years. A specimen collected from the Ritidian NWR in August 2013 is currently pending identification (USFWS 2014a). There are no records of the species within the impacted areas of Alternative D (USFWS 2014b). Therefore, as *P. malaspinae* is not found within the impacted areas of Alternative D, this species is not addressed further.

**SOLANUM GUAMENSE.** A small shrub in the nightshade family that occurs within limestone forests. Currently, *S. guamense* is known from a single occurrence of one individual on Guam (USFWS 2014a). There are no records of the species within the impacted areas of Alternative D. Therefore, as *S. guamense* is not found within the impacted areas of Alternative D, this species is not addressed further.

**TINOSPORA HOMOSEPALA.** A vine in the moonseed family found in limestone forests. Currently, *T. homosepala* is known from 3 occurrences totaling approximately 300 individuals: 1 occurrence on the western side of Asan Ridge; 1 occurrence near the War in the Pacific Historical Park; and 1 occurrence on the cliff face at Hagåtña (USFWS 2014a). There are no records of the species within the impacted areas of Alternative D (USFWS 2014b). Therefore, this species is not addressed further.

**TUBEROLABIUM GUAMENSE.** An epiphyte in the orchid family found in limestone forests. Currently, *T. guamense* is known from 3 occurrences on Guam: 2 within the NAVMAG and 1 in the northeastern area of Finegayan (see Figure 4.1.8-4) (NAVFAC Pacific 2010; USFWS 2014a, 2014b). There are no records of the species within the impacted areas of Alternative D (USFWS 2014b). Therefore, as *T. guamense* is not found within the impacted areas of Alternative D, this species is not addressed further.

**Special-Status Species: Guam-Listed Species and SOGCN**

Two Guam-listed endangered species (moth skink and Micronesian starling) occur on support areas on AAFB and adjacent lands; none are known to occur on Barrigada (Table 4.4.8-1).

**MICRONESIAN STARLING.** The Micronesian starling has not been reported for Barrigada. The starling is present in the housing area at AAFB (JRM 2013; J. Savidge, Colorado State University, personal communication to G. Metzler, Cardno TEC, May 23, 2013) and has also been observed occasionally throughout AAFB (NAVFAC Pacific 2010; JRM *et al.* 2012d; JRM 2013) (see Figure 4.1.8-5).
WHITE-THROATED GROUND DOVE. The white-throated ground dove is reported as extirpated from Guam due to the brown treesnake (GDAWR 2006). Although occasionally seen on AAFB within the MSA, it has not been reported within the utility support areas associated with Alternative D. There are no records of the ground dove occurring at Barrigada. Therefore, as the white-throated ground dove is not found within the impacted areas of Alternative D, this species is not addressed further.

Moth Skink and Pacific Slender-toed Gecko. Although both species have been observed within AAFB, only the moth skink has been observed within proposed utility impacted areas along the southern boundary of the base (see Figure 4.1.8-5) (NAVFAC Pacific 2010). Moth skinks and slender-toed geckos have also been observed by USGS biologists within the HMU (R. Reed, USGS Brown Treesnake Project, personal communication, April 24, 2013). Based on previous surveys within proposed impacted areas on AAFB in support of the 2010 Final EIS and this SEIS (NAVFAC Pacific 2010, 2013a), there are no known occurrences of the Pacific slender-toed gecko within the Alternative D impacted areas. Proposed water well utilities would avoid the HMU where the Pacific slender-toed gecko is known to be present. Therefore, as the Pacific slender-toed gecko is not found within the impacted areas of the Alternative D, this species is not addressed further.

4.4.8.2 Environmental Consequences

Construction

Vegetation. The vegetation communities that would be impacted during proposed facility and infrastructure construction activities under Alternative D are shown in Figure 4.4.8-1 for the cantonment and housing area and in Figure 4.1.8-2 for the support areas. Approximately 99 acres (40 ha) of primary limestone forest and 133 acres (54 ha) of secondary limestone forest would be impacted during proposed construction activities at Barrigada and associated support areas (Table 4.4.8-2 and Figure 4.4.8-1). Approximately 735 acres (297 ha) of herbaceous scrub and tangantangan would also be impacted, as well as 461 acres (186 ha) of currently developed areas (Table 4.4.8-2). The wetland area of 0.3 acre (1.4 ha) is associated with the pond on the currently closed Nimitz Golf Course. Refer to Section 4.2.2.2 for the discussion of impacts to wetlands.

Legend: PLF = primary limestone forest; SLF = secondary limestone forest; HS = herbaceous scrub; TT = tangantangan; Ag = agriculture; Dev = developed; Wet = wetland.
Native limestone forest, both primary and secondary, has been significantly reduced on Guam due to past and ongoing actions including extensive disturbance during and after WWII, widespread planting of non-native species, and impacts from non-native ungulates, development, fire, and deforestation. As stated in Section 3.8.1.1, limestone forests on Guam are important since they retain the functional ecological components of native forest that provide habitat for the majority of Guam’s native species, including ESA-listed, ESA-proposed, and Guam-listed species and Guam SOGCN, as well as maintaining water quality and reducing fire risk. Non-native forest communities (e.g., tangantangan, Vitex) significantly alter the forest structure, composition, and resilience to other disturbance processes and do not provide the conditions suitable for native flora and fauna species to persist (Morton et al. 2000; GDAWR 2006; Guam Department of Agriculture 2010; JRM 2013).

Of the 18,538 acres (7,502 ha) of primary and secondary limestone forest found on Guam, approximately 13,110 acres (5,305 ha) (or 71%) are found primarily within AAFB, Finegayan, and NAVMAG (USFS 2006). Under Alternative D, approximately 99 acres (40 ha) of primary limestone forest and 133 acres (54 ha) of secondary of limestone forest would be developed, primarily within Barrigada, but also within the utility corridors common to all cantonment/family housing alternatives (Table 4.4.8-2). Therefore, given the importance of limestone forest habitat for native species and the continuing loss of limestone forest across Guam, the conversion of 231 acres (94 ha) of limestone forest on Barrigada and supporting areas under Alternative D to developed area would be a significant but mitigable impact to the regional vegetation community and its function.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct, long-term impacts of proposed construction activities on vegetation communities with implementation of Alternative D. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of Biosecurity Outreach and Education.
- **Contractor Education Program.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the contractor education program.
- **Onsite Vegetation Waste Management Procedures.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the vegetation waste management procedures.
- **DON Guam Landscaping Guidelines.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of landscaping guidelines.
- **Contractor Plans and Specifications.** All construction will occur within the limits of construction shown in the project figures. Contractors will be responsible for any unauthorized vegetation damage and will not move outside the designated construction zone.

Potential Mitigation Measures

To mitigate for significant impacts to limestone forest, the DON proposes to implement forest enhancement on a minimum of 231 acres (94 ha) of limestone forest. Forest enhancement would include but is not limited to the following actions:

- Ungulate management consisting of exclusion fencing and active control (i.e. trapping, snaring, shooting) with the goal of eradication within the fenced areas.
- Non-native, invasive vegetation removal.
- Propagation, planting, and establishment of native species that are characteristic of native limestone forest habitats (e.g., A. mariannensis, G. mariannae, F. prolita, M. citrifolia, W. elliptica).

The degradation and loss of primary limestone and other forest habitats resulting from ungulate damage and invasion by alien plant species has substantially diminished the extent of habitat for native species in the Mariana archipelago. The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including special-status species. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

**Terrestrial Conservation Areas.** The cantonment and housing areas under Alternative D would not be located on Overlay Refuge lands. However, proposed utility areas common to all alternatives would impact 48 acres (20 ha) of Overlay Refuge lands (Table 4.4.8-3). This 48 acres (20 ha) is less than 1% of the total Overlay Refuge lands on Guam. Therefore, because proposed construction activities would impact a very small percentage of Overlay Refuge lands, the conversion of 48 acres (20 ha) of Overlay Refuge lands to developed areas would be a less than significant impact.

**Table 4.4.8-3. Impacts to Overlay Refuge at Barrigada and Support Areas with Implementation of Cantonment/Family Housing Alternative D**

_Legend: PLF = primary limestone forest; SLF = secondary limestone forest; HS = herbaceous scrub; TT = tangantangan; CP = coconut plantation; CF = Casuarina forest; Dev = developed._

**Wildlife - Native Species.** Impacts to commonly occurring wildlife on Barrigada were evaluated in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.4.2: Central, page 10-183). Based on that analysis, impacts to these common species would be less than significant.

Native bird species reported for Barrigada and support areas on AAFB are predominantly migratory shorebird species and primarily use open areas such as grassy fields. The proposed construction at Barrigada and AAFB would not reduce the amount of these open space areas. The conversion of forested areas to open areas and the proposed construction for utility corridors would result in additional open space. The loss of woody vegetation would result in the loss of nesting areas for the yellow bittern, but this loss would not result in significant adverse effects on the bittern population on Guam because suitable nesting habitat occurs throughout the island. Short-term construction noise may temporarily impact suitable habitat for some birds in the vicinity of the construction areas, but they would relocate to other open and forested areas on Barrigada and AAFB, and could return to the area following construction. Implementation of Alternative D would not have a significant adverse effect on a population of any migratory bird species or other native wildlife species. Non-listed native reptiles are abundant throughout Guam and impacts to vegetation communities under Alternative D would result in less than significant impacts to non-listed native reptile populations.
Therefore, as presented above, long-term, direct impacts to populations of native wildlife species would not result because these species are abundant in surrounding areas and could repopulate portions of suitable habitat within the affected area after construction. Therefore, direct impacts to native wildlife would be less than significant with implementation of proposed construction activities associated with Alternative D.

Proposed construction activities and associated movement of materials onto and off of Guam could increase the potential for the spread of existing or introduction of new non-native invasive species. To prevent the inadvertent spread of non-native species on Guam or to other locations off of Guam, the DON would implement standard biosecurity measures (e.g., HACCP, brown treesnake interdiction measures, coconut rhinoceros beetle vegetation management procedures, outreach/education, and monitoring to evaluate effectiveness of HACCP) into construction protocols, procedures, and activities.

The following BMPs would be implemented to avoid and minimize potential direct, long-term impacts of proposed construction activities on native wildlife with implementation of Alternative D.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

With implementation of these BMPs, including development of HACCP plans and ongoing implementation of standard DON biosecurity protocols regarding detection and management of non-native species (e.g., coconut rhinoceros beetle), the risk of the introduction and establishment of new or spread of existing non-native species on Guam is substantially reduced. Therefore, there would be less than significant impacts to native wildlife species related to the potential introduction and establishment of non-native species with implementation of proposed construction activities associated with Alternative D.

Damage of forested areas, particularly primary and secondary limestone forests, by non-native ungulates (i.e., deer and pigs) is a serious concern on Guam. Under Alternative D, removal of large amounts of secondary limestone forest currently used by ungulates would displace and concentrate ungulates into adjacent areas, resulting in even higher densities and potentially greater habitat damage. Potential impacts from changes in ungulate densities from construction projects within the same or similar habitat areas as proposed in this SEIS were addressed in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.2.1: North, page 10-115).

The implementation of the potential mitigation measures under the Vegetation section above would also benefit native wildlife species. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures.
Special-Status Species: Federal ESA-Listed and Proposed Species

MARIANA FRUIT BAT. Approximately 48 acres (19 ha) of Mariana fruit bat recovery habitat would be removed due to proposed construction activities associated with utility and water well areas on AAFB under Alternative D (Table 4.4.8-4). This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

</tbody>
</table>

The species is currently limited to the few areas on Guam away from human activities and with suitable habitat, primarily on federal lands on the NAVMAG and AAFB (JRM et al. 2012a, 2012b; JRM 2013; A. Brooke, NAVFAC Marianas, personal communication). However, illegal hunting, loss and degradation of native forest, predation by the brown treesnake, and the increased extirpation risk owing to the high vulnerability of very small populations continue to limit the potential recovery of the species on Guam (USFWS 2010; JRM 2013). Based on the equilibrium/carrying capacity of snakes on Guam (Rodda and Savidge 2007), implementation of the proposed action is not expected to increase the likelihood of predation by the brown treesnake on Mariana fruit bats.

The loss of 48 acres (19 ha) of fruit bat recovery habitat on Guam would not preclude the recovery or survival of the fruit bat, and it would not substantially reduce the total number of bats that the island can support. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to the Mariana fruit bat with implementation of proposed construction activities associated with Alternative D.

The following BMPs may be implemented to avoid and reduce potential direct long-term impacts of proposed construction activities on Mariana fruit bats and recovery habitat with implementation of Alternative D.

Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Pre-Construction Surveys.** Surveys would be completed within suitable fruit bat habitat 1 week prior to onset of construction activities following the USFWS-approved JRM protocol. If a fruit bat is present within 492 feet (150 m) of the project site, the work must be postponed until the bat has left the area.
- **Lighting Installation.** Lighting would be designed to meet minimum safety and AT/FP requirements. Hooded lights would be used to the maximum extent practicable at all new
roads and facilities adjacent to fruit bat habitat. Illumination of forest would be kept to an absolute minimum.

In addition, the potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 231 acres [94 ha] of limestone forest) would provide additional benefit to bat recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Mariana fruit bat.

MARIANA CROW. The Mariana crow is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the crow is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the crow, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the crow is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative D, impacts to the crow would be limited to recovery prospects. If crows are reintroduced and exposed to construction activities associated with Alternative D, they may be disturbed (DON 2014).

Although the crow no longer occurs on Guam, approximately 48 acres (19 ha) of crow recovery habitat would be removed due to proposed construction activities associated with utility and water well areas on AAFB under Alternative D (Table 4.4.8-5). This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

| Table 4.4.8-5. Summary of Permanent Construction-Related Impacts to Mariana Crow Recovery Habitat with Implementation of Cantonment/Family Housing Alternative D |
|-------------------------------------------------|---------------------------------|
| **Project Component**                          | **Recovery Habitat**            |
|                                                 | (acres [ha])                    |
| Barrigada cantonment and housing                | 0                               |
| Utility corridor specific to Alternative D      | 0                               |
| Utility corridors and water well areas common to Alternatives A-E | 48.0 (19.4)                      |
| **Total Recovery Habitat Impacted**            | **48.0 (19.4)**                 |

This loss of recovery habitat on Guam would not preclude the recovery or survival of the crow should it be reintroduced to Guam in the future, and it would not substantially reduce the total number of crows that the island can support. This loss of recovery habitat on Guam would not preclude the recovery or survival of the crow should it be reintroduced to Guam in the future, and it would not substantially reduce the total number of crows that the island can support. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to the Mariana crow with implementation of proposed construction activities associated with Alternative D. If and when the crow is reintroduced to Guam, the best available information indicates project-related noise would not further reduce the amount of recovery habitat suitable for this species’ breeding, feeding and sheltering (USFWS 2010).

The following BMPs may be implemented to avoid and reduce potential direct long-term impacts of proposed construction activities on Mariana crow recovery habitat with implementation of Alternative D.
Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2, *Construction, Vegetation* for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, *Construction, Vegetation* for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, *Construction, Vegetation* for a detailed description of the contractor education program.
- **Brown Treesnake Interdiction.** See Section 4.1.8.2, *Construction, Wildlife - Native Species* for a detailed description of the brown treesnake interdiction program.

In addition, the potential mitigation measures discussed above under *Vegetation* (i.e., forest enhancement of 231 acres [94 ha] of limestone forest) would provide additional benefit to crow recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Mariana crow, should it be reintroduced to Guam in the future.

**GUAM RAIL.** The Guam rail is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the rail is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the rail, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the rail is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative D, impacts to the rail would be limited to recovery prospects. If rails are reintroduced and exposed to construction activities under Alternative D, they may be disturbed (DON 2014).

Although the rail no longer occurs on Guam, approximately 864 acres (350 ha) of rail recovery habitat would be removed due to proposed construction activities at Barrigada and the AAFB support areas under Alternative D (Table 4.4.8-6). This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

Although this loss of recovery habitat on Guam would not preclude the recovery of the rail should it be reintroduced to Guam in the future, it would reduce the total number of rails that the island can support. Given this loss of recovery habitat, there would be significant but mitigable impacts to the recovery of the Guam rail.
The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct and indirect long-term impacts of proposed construction activities on the recovery of the Guam rail with implementation of Alternative D. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

**Potential Mitigation Measures**

- **Brown Treesnake Suppression or Eradication.** See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW for a detailed description of the brown treesnake suppression or eradication program.
- The same potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 231 acres [94 ha] of limestone forest) would benefit Guam rail recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Guam rail, should it be reintroduced to Guam in the future.

**GUAM MICRONESIAN KINGFISHER.** The Guam Micronesian kingfisher is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the kingfisher is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the kingfisher, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the kingfisher is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative D, impacts to the kingfisher would be limited to recovery prospects. If kingfishers are reintroduced and exposed to construction activities under Alternative D, they may be disturbed (DON 2014).

Although the kingfisher no longer occurs on Guam, approximately 48 acres (19 ha) of kingfisher recovery habitat would be removed due to proposed construction activities associated with utility and water well areas on AAFB under Alternative D (Table 4.4.8-7). This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.
Table 4.4.8-7. Summary of Permanent Construction-Related Impacts to Guam Micronesian Kingfisher Recovery Habitat with Implementation of Cantonment/Family Housing Alternative D

<tr>
<td><strong>Total Recovery Habitat Impacted</strong></td>
<td><strong>48.0 (19.4)</strong></td>
</tr>
</tbody>
</table>

The loss of 83 acres (34 ha) of kingfisher recovery habitat on Guam would not preclude the recovery of the kingfisher, and it would not substantially reduce the total number of kingfishers that the island can support. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to the kingfisher with implementation of proposed construction activities associated with Alternative D.

The following BMPs may be implemented to avoid and reduce potential direct long-term impacts of proposed construction activities on kingfisher recovery habitat with implementation of Alternative D.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

In addition, the potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 231 acres [94 ha] of limestone forest) would provide additional benefit to kingfisher recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Guam Micronesian kingfisher, should it be reintroduced to Guam in the future.

**Mariana Common Moorhen.** As noted in Section 4.4.8.1, moorhens have been observed at the Nimitz Golf Course pond, although nesting has not been recorded. The pond is probably used as a temporary resting area while transiting to other ponds throughout Guam such as those identified in the recovery plan for the species (USFWS 1991). Therefore, the loss of the one pond within Barrigada under Alternative D would be a less than significant impact to the Mariana common moorhen.

**Guam Tree Snail.** Although the Guam tree snail was documented in the secondary limestone forest at Navy Barrigada in 2008, it was not observed during surveys in 2013 in support of this SEIS (UoG 2014). Increased degradation of the secondary limestone forest by ungulates (i.e., pigs) may have resulted in the loss of suitable tree snail habitat at Barrigada (NAVFAC Pacific 2013a; UoG 2014). Surveys have not been conducted within the primary limestone forest in the northern portion of Barrigada associated with Mount Barrigada. Therefore, the loss of 266 acres (108 ha) of primary and secondary limestone forest habitat at Barrigada would be a significant but mitigable impact to the Guam tree snail.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct and indirect long-term impacts of proposed construction activities on the Guam
tree snail with implementation of Alternative D. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

### Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

### Potential Mitigation Measures

- **Brown Treesnake Suppression or Eradication.** See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW for a detailed description of the brown treesnake suppression or eradication program.
- The implementation of the potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 231 acres [94 ha] of limestone forest) would benefit tree snail species and habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Guam tree snail.

**SERIANTHES TREE.** Although individual Serianthes trees do not occur within the impacted areas of Alternative D, approximately 41 acres (17 ha) of Serianthes recovery habitat would be removed due to proposed construction activities at the AAFB support areas (Table 4.4.8-8). See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

### Table 4.4.8-8. Summary of Direct Construction-Related Impacts to Serianthes Recovery Habitat with Implementation of Cantonment/Family Housing Alternative D

This loss of recovery habitat on Guam would not preclude the recovery of Serianthes, and it would not substantially reduce the total number of Serianthes that the island can support. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to Serianthes with implementation of proposed construction activities associated with Alternative D.

The following BMPs may be implemented to avoid and minimize, potential direct long-term impacts of proposed construction activities on the recovery of Serianthes with implementation of Alternative D.

### Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.
• Biosecurity Outreach and Education. See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.

• Contractor Education Program. See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

The implementation of the potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 231 acres [94 ha] of limestone forest) would benefit Serianthes habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

Special-Status Species: Guam-Listed and SOGCN

MICRONESIAN STARLING. This species has not been recorded in Barrigada and is rarely observed within the AAFB support areas. Therefore, there would be no impacts to the starling with implementation of Alternative D.

MOTH SKINK. A single moth skink was detected in a proposed utilities area along the southern border of AAFB within secondary limestone forest during surveys for this SEIS (NAVFAC Pacific 2013a) (Figure 4.1.8-5). Therefore, due to the extremely low occurrence of the skink within the proposed impacted areas, there would be less than significant impacts to the species with implementation of the proposed construction activities associated with Alternative D. However, implementation of the potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 231 acres [94 ha] of limestone forest) would benefit the moth skink and its habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the moth skink.

Operation

Operational impacts would only occur for the proposed Alternative D. Operational requirements for the proposed utilities would require only periodic, limited maintenance activities along established utility corridors and impacts to biological resources would be less than significant. Consequently, only the potential operational impacts at the Alternative D are evaluated below.

Vegetation. With implementation of BMPs and potential mitigation measures, including invasive species outreach and education and applicable elements of the SIP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of the cantonment and housing area under Alternative D is considered unlikely. Therefore, there would be less than significant impacts to vegetation with operation under Alternative D.

Terrestrial Conservation Areas. There are no terrestrial conservation areas at Barrigada. Although Overlay Refuge lands occur within the utility corridors and support areas on AAFB, operational requirements for the proposed utilities would require only periodic, limited maintenance activities along established utility corridors and impacts to biological resources would be less than significant.
Wildlife - Native Species. Potential impacts to wildlife were evaluated in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.2.1: North, page 10-101) for a similar proposed action but impacting a larger area, and were found to be less than significant.

Proposed operational activities and associated movement of materials onto and off of Guam could increase the potential for the spread of existing or introduction of new non-native invasive species. The following BMPs would be implemented to avoid and minimize potential indirect, long-term impacts of proposed operational activities on native wildlife with implementation of Alternative D.

**Best Management Practices**

- **Biosecurity Outreach and Education.** See the previous discussion of BMPs under construction impacts to Vegetation for a detailed description of Biosecurity Outreach and Education.

- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

- **Lighting Installation.** Lighting would be designed to meet minimum safety and AT/FP requirements. Hooded lights would be used to the maximum extent practicable at all new roads and facilities adjacent to fruit bat habitat. Illumination of forest would be kept to an absolute minimum.

- **Prevention of Free-Roaming Cats and Dogs.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of DON policies regarding free-roaming cats and dogs.

With implementation of these BMPs, including ongoing implementation of standard DON biosecurity protocols regarding detection and management of non-native species and 1-year post-construction monitoring to evaluate effectiveness of HACCP, the risk of the introduction and establishment of new or spread of existing non-native species on Guam is substantially reduced.

The implementation of the potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 266 acres [107 ha] of limestone forest) would benefit habitat for native wildlife. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna.

**Special-Status Species: ESA-Listed and Proposed Species**

MARIANA FRUIT BAT. There are no historical fruit bat roost sites at Barrigada and there have been no observations of fruit bats at Barrigada since 1999. Although fruit bat recovery habitat occurs within the utility corridors and support areas on AAFB, operational requirements for the proposed utilities would require only periodic, limited maintenance activities along established utility corridors and impacts to Mariana fruit bats would be less than significant.

The following BMPs and potential mitigation measures may be implemented to avoid and reduce potential long-term impacts of proposed operational activities on the Mariana fruit bat with implementation of Alternative D.
Best Management Practices

- *Lighting Installation*. Lighting would be designed to meet minimum safety and AT/FP requirements. Hooded lights would be used to the maximum extent practicable at all roads and facilities adjacent to fruit bat habitat. Illumination of forest would be kept to an absolute minimum.

The implementation of the potential mitigation measures discussed above under *Vegetation* (i.e., forest enhancement of 266 acres [107 ha] of limestone forest) would benefit habitat for the fruit bat and recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Mariana fruit bat.

MARIANA CROW, GUAM RAIL, AND GUAM MICRONESIAN KINGFISHER. These species are extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when re-introduction of these species is reasonably certain to occur and the species are likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of these species, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the crow, rail, and kingfisher are successfully re-introduced and then have the potential to be exposed to cantonment and housing operational activities under Alternative D, there would be no impact to these species. If the species are reintroduced and exposed to cantonment and housing operational activities under Alternative D, they may be disturbed.

MARIANA COMMON MOORHEN. As there would be no suitable moorhen habitat (i.e., open water) within Alternative D after construction, there would be no impacts to moorhens due to operations associated with Alternative D.

TREE SNAILS. As there would be no suitable tree snail habitat within Alternative D after construction, there would be no impacts to tree snails due to operations associated with Alternative D.

SERIANTHES TREE. There would be no operational impacts to *Serianthes* or recovery habitat on AAFB with implementation of Alternative D.

Special-Status Species: Guam-Listed and SOGCN

MICRONESIAN STARLING. As this species has not been recorded from Barrigada, there would be no impacts to the starling due to operations associated with Alternative D.

MOTH SKINK. As there would be no suitable moth skink habitat within Alternative D after construction, there would be no impacts to the moth skink due to operations associated with Alternative D.
4.4.9 Marine Biological Resources

4.4.9.1 Affected Environment

The affected environment for marine biological resources was not analyzed for the Barrigada study area in the 2010 Final EIS (Volume 2, Chapter 11: Marine Biological Resources, Section 11.1.6.2 Barrigada, page 11-51) as there were no in-water construction, dredging, or training activities proposed and/or land-based construction activities that would affect the marine environment. This is consistent with the proposed Alternative D; however, a brief description of the resources in the area is presented here to provide context for the discussion of WWTP upgrades and potential indirect impacts to marine biological resources from increased recreational use resulting from an increased population. Marine biological resources would not be impacted by Alternative D with respect to facilities common to all alternatives (i.e., schools and off-site utilities).

Alternative D would be located at an elevation ranging from approximately 200 to 400 feet (60 to 120 m) and more than 0.5 mile (0.8 km) from the coast and the BEQ/BOQ project area on AAFB would be located at an approximate elevation of 500 feet (150 m) and 0.7 mile (1.2 km) from the coast, and by extension, marine biological resources. The coastline here, between Pågat Point and Pago Bay, has few beaches - primarily small coves near Mangilao Golf Club that are privately owned. A trail called Thousand Steps consists of approximately 150 steep steps that provide public access to the beach at the Mangilao Golf Club. Uog Beach is noted as a Guam dive site.

General water quality is discussed under Section 4.4.1.3, Water Resources under Nearshore Waters for Agaña Bay, where the outlet for the Agaña WWTP (the WWTP utilized by Barrigada) is located.

Marine Flora and Invertebrates

The area around Barrigada moves from coralline algae to the north and macroalgae to the south to coral coverage of 10-50% to turf algae and unconsolidated sediment (Figure 4.4.9-1).

Fish

Despite the lack of beaches, fishing along the eastern coast of Guam is popular. Fishing in this area is primarily done by boat and only when ocean conditions allow. Fish biomass measured during the 2007 NOAA Pacific Islands Fisheries Science Center Coral Reef Ecosystem Division surveys, was the third highest of surveyed fish sites around Guam, and was dominated by parrotfish and surgeonfish (Williams et al. 2012).

Essential Fish Habitat

EFH-designated habitat areas east of Barrigada are those defined for bottomfish, crustaceans, coral reef ecosystems, precious corals, and Pacific pelagics. Benthic, coral reef, and fish condition in comparison to other survey areas around Guam, Rota, Tinian, and Saipan were ranked as low to medium-low from 2005 and 2007 survey index values (Williams et al. 2012).
Figure 4.4.9-1
Overview of Sensitive Marine Biological Resources and Nearshore Habitat – Barrigada Cantonment/Housing Alternative D

Sources: NOAA 2005a, b; NAVFAC Pacific 2013
Special-Status Species

Information on the presence of coral species listed as threatened under the ESA is lacking, but for the purposes of this SEIS, the coral species listed for AAFB under Section 3.9.9.1, Special-Status Species in Table 4.3.9-1 are assumed to be present along the coast by Barrigada as well.

A sea turtle sighting has been recorded offshore from the Mangilao Golf Club; however, green sea turtle nesting primarily occurs in northern Guam and has not been recorded in the area (hawksbill sea turtle nesting on Guam is extremely rare). For the purposes of this SEIS, green and hawksbill sea turtles are assumed to be present in the waters to the east of central Guam.

ESA-listed threatened scalloped hammerhead sharks have only been documented in Guam’s Outer Apra Harbor, which has been noted for neonate and juvenile aggregations. While scalloped hammerhead sharks may occur in the surrounding waters around Guam, they are not anticipated to be prevalent outside Guam’s Outer Apra Harbor.

There is no information on NMFS species of concern specific to the waters east of Barrigada. However, the presence of the bumphead parrotfish is likely given the high abundance of large fish, including generally classified parrotfish. The humphead parrotfish is not expected to occur in the waters around Barrigada.

Marine Conservation Areas

There are no marine conservation areas in the vicinity of Barrigada.

4.4.9.2 Environmental Consequences

Construction

Construction of the cantonment, family housing, and community support facilities would take place at Barrigada under this alternative. There are no anticipated direct impacts to marine resources as a result of the construction of the Alternative D. Construction of facilities common to all alternatives (i.e., schools and off-site utilities) would have no impact on marine biological resources.

In addition, all marine biological resources would be affected by the increased wastewater discharge from the Agaña WWTP for treatment and disposal of generated wastewater for the cantonment and housing at Barrigada and the Northern District WWTP for facilities located at AAFB. As discussed in Section 4.4.14, Utilities, in this SEIS, direct and indirect long-term impacts to wastewater from DoD and organic civilian population growth are estimated to increase the maximum monthly wastewater flows to the Northern District WWTP by 2028. Due to the reduced population projection and related smaller increase in demand under the 2012 Roadmap Adjustments, these increases in wastewater discharge from the Agaña WWTP and the Northern District WWTP would be less than under the No-Action Alternative. However, as described in Section 4.1.9.2 for Alternative A, the Northern District WWTP and Agaña WWTPs are out of compliance with their permit issued by USEPA in April 2013 and increasing the wastewater discharge from non-compliant treatment plants would result in significant indirect impacts to marine biological resources during the period of noncompliance. Upgrading the Northern District and Agaña WWTPs treatment systems (as required by the 2013 NPDES permit) would mitigate this significant impact to marine biological resources.

Impacts to water quality for marine biological resources resulting from increased WWTP wastewater discharges are discussed here and are not included in the analysis for each subcategory of marine biological resources below, which are limited to stormwater, sedimentation, and other non-point source...
pollution and recreational impacts. The measures used to minimize these potential impacts include appropriate resource agency specific BMPs, construction and industrial permit BMPs, LID features in accordance with the DoD UFC LID (UFC 3-210-10) and Section 438 of the EISA, USACE permit conditions, and general marine resources protective measures, are described in the 2010 Final EIS (Volume 7 and Volume 2, Chapter 11: Marine Biological Resources, Section 11.2: Environmental Consequences, pages 11-70 to 11-71) and summarized in Chapter 2 of this SEIS. Specifically, the site-specific SWPPP within the Construction General Permit would identify appropriate BMPs for the site that would serve to contain runoff and sediment on-site by reducing the flowrate of runoff and thereby minimize suspension of sediment and promote infiltration of runoff.

**Marine Flora and Invertebrates**

The construction of the cantonment and housing at Barrigada would not directly impact marine flora and invertebrates. These resources would not be impacted directly by the proposed action because there are no in-water or land-based construction, dredging, or training activities associated with the proposed cantonment and housing construction at Barrigada that would impact the marine environment.

Indirect impacts to the coral reef ecosystem located near the project area may occur from increased use of this resource by construction workers. The magnitude of impacts is directly related to the increase in recreational use. However, contract construction personnel would be issued base passes for official business only and these restrictions would be specified in construction contracts.

The DON plans to educate construction workers via environmental awareness training on the importance of coastal ecosystems and the proper way to interact with those resources to avoid and minimize damage to reefs typically caused by anchors, reef-walkers, or scuba diving, snorkeling, and fishing activities around Guam. Indirect short-term impacts to marine flora and invertebrates may still occur from increased nearshore activities in the area by construction workers.

With implementation of access restrictions and environmental education and outreach for the construction workforce, there would be no direct impacts and less than significant indirect short-term impacts to marine flora and invertebrates.

**Fish**

With implementation of access restrictions and environmental education and outreach for the construction workforce as described above for Marine Flora and Invertebrates, there would be no direct impacts and less than significant indirect short-term impacts to fish as a result of construction of the proposed cantonment and housing at Barrigada.

**Essential Fish Habitat**

The construction of Alternative D would result in no direct impacts and less than significant indirect impacts to EFH for reasons consistent with those given above for marine flora and invertebrates. There would be no impacts to EFH from stormwater, sedimentation, or other non-point source pollution from construction projects due to compliance with the Construction General Permit and the implementation of appropriate construction BMPs.

Per the Magnuson-Stevens Fishery Conservation and Management Act, there would be no adverse effect on EFH because construction of the proposed action would not reduce the quality or quantity of EFH with implementation of access restrictions, environmental education and outreach for the construction workforce, and the Construction General Permit and appropriate construction BMPs.
Special-Status Species

There would be no direct impacts and less than significant indirect impacts on special-status species as a result of the distance from the construction area to the shoreline, implementation of the Construction General Permit, implementation of appropriate construction BMPs, and access limitations for construction workers, as described for the resources above.

In-water sea turtles may be disturbed by increased recreational activity but potential impacts would be short-term and minimal, and generally unlikely given the distance of the proposed cantonment and housing from any beach used for recreation. Therefore, there would be less than significant, indirect impacts to sea turtles.

Marine Conservation Areas

There are no marine conservation areas near Barrigada; therefore, there would be no impacts to marine conservation areas as a result of the construction of Alternative D.

Operation

Marine biological resources would be impacted by the increased wastewater discharge from the Northern District WWTP and Agaña WWTP during the operation of cantonment/family housing under Alternative D. The associated potential impacts would be similar to those described earlier in this section for construction-related impacts. However, upgrades to bring the Northern District WWTP and Agaña WWTP into compliance with the permits are expected to be completed early in the operational phase of the proposed action and such upgrades would mitigate the impact to a less than significant level. Refer to construction impacts above for a detailed discussion of WWTP discharge impacts.

As discussed in Section 4.4.14, Utilities, in this SEIS, direct and indirect long-term impacts to wastewater from DoD and organic civilian population growth are estimated to increase the maximum monthly wastewater flows to the Northern District WWTP by 2028. Due to the reduced population projection and related smaller increase in demand under the 2012 Roadmap Adjustments, these increases in wastewater discharge from the Agaña WWTP and the Northern District WWTP would be less than under the No-Action Alternative. However, as described in Section 4.1.9.2 for Alternative A, the Northern District WWTP and Agaña WWTPs are out of compliance with their permit issued by USEPA in April 2013 and increasing the wastewater discharge from non-compliant treatment plants would result in significant indirect impacts to marine biological resources during the period of noncompliance. Upgrading the Northern District and Agaña WWTPs (as required by the 2013 NPDES permit) would mitigate this significant impact to marine biological resources. Potential mitigation to address this significant impact would be as described in the wastewater impact discussion for Alternative A in Section 4.1.2.2 but would include assistance with upgrading both the Agaña WWTP and Northern District WWTP. Therefore, with the potential mitigation measures, the impact to marine biological resources via water quality would be beneficial in the long term because wastewater discharge from the Agaña and Northern District WWTPs would improve over existing conditions with upgrades. Impacts to water quality for marine biological resources resulting from increased WWTP wastewater discharges are discussed here and are not included in the analysis for each subcategory of marine biological resources below, which are limited to stormwater, sedimentation, and other non-point source pollution and recreational impacts.

Marine Flora and Invertebrates

The operation of the cantonment and housing at Barrigada would not directly impact marine flora and invertebrates. These resources would not be modified from existing conditions considering the distance...
and elevation from the shoreline and the implementation of protective measures to prevent stormwater runoff from reaching nearshore waters.

The DON plans to educate its service members and their dependents via environmental awareness training on the importance of coastal ecosystems and the proper way to interact with those resources to avoid and minimize damage to reefs typically caused by anchors, reef-walkers, or scuba diving, snorkeling, and fishing activities. The Environmental Compliance Assessment, Training and Tracking System program is one possibility for such an educational training program to minimize these potential increased, recreational impacts to marine flora and invertebrates.

Implementation and enforcement of appropriate BMPs (provided in Chapter 2) and protective measures would further avoid and minimize potential long-term, indirect impacts to marine flora and invertebrates from stormwater, sedimentation, and other non-point source pollution from operational activities. For example LID measures would include vegetated swales for conveyance and detention/retention ponds capable of capturing, storing, and treating additional runoff from the 25-year design storm. For each basin, water quality treatment strategies were selected based on the effectiveness of BMPs to treat identified pollutants of concern from proposed land uses within that basin. Implementation of LID measures would ensure that there would be no increase in off-site transport of excess stormwater runoff, sediment, or other pollutants for up to the 25-year design storm event.

With implementation of environmental education and outreach for DON service members and their dependents and operation and maintenance of LID measures and BMPs, there would be no direct impacts and less than significant indirect short-term impacts to marine flora and invertebrates.

**Fish**

There would be no direct impacts to fish as a result of the operation of the cantonment and housing at Barrigada. Indirect impacts to fish stocks may occur from increased use of this resource by DoD personnel and their dependents living and working at Barrigada. The magnitude of impacts is directly related to the increase in recreational use.

The DON plans to educate its service members and their dependents via environmental awareness training on the importance of coastal ecosystems and the proper way to interact with those resources to avoid and minimize damage to reefs typically caused by anchors, reef-walkers, or scuba diving, snorkeling, and fishing activities. The Environmental Compliance Assessment, Training and Tracking System program is one possibility for such an educational training program to minimize these potential increased recreational impacts to fish.

Implementation and enforcement of appropriate BMPs (provided in Chapter 2) and protective measures would further avoid and minimize potential long-term, indirect impacts to fish from stormwater, sedimentation, and other non-point source pollution from operational activities. For example, LID measures would include vegetated swales for conveyance and detention/retention ponds capable of capturing, storing, and treating additional runoff from the 25-year design storm. For each basin, water quality treatment strategies were selected based on the effectiveness of BMPs to treat identified pollutants of concern from proposed land uses within that basin. Implementation of LID measures would ensure that there would be no increase in off-site transport of excess stormwater runoff, sediment, or other pollutants for up to the 25-year design storm event.

With implementation of environmental education and outreach for DON service members and their dependents and operation and maintenance of LID measures and BMPs, there would be no direct impacts and less than significant indirect short-term impacts to fish.
Essential Fish Habitat

The operation of the cantonment and housing at Barrigada would result in no direct impacts and less than significant indirect impacts to EFH for reasons consistent with those given above for marine flora and invertebrates. With implementation of environmental education and outreach for DON service members and their dependents and operation and maintenance of LID measures and BMPs, there would be no direct impacts and less than significant indirect short-term impacts to EFH as a result of stormwater, sedimentation, and other non-point source pollution and recreational impacts. Per the Magnuson-Stevens Fishery Conservation and Management Act, the DON has determined that during the interim period of change when the effluent discharged from the Agaña and Northern District WWTPs would not meet Guam Water Quality Standards, the proposed action may adversely affect EFH, but effects would be temporary and less than significant (see discussion above under Operation). In accordance with the Magnuson-Stevens Fishery Conservation and Management Act, the DON has requested consultation with NMFS about effects to EFH during the interim period.

Special-Status Species

There would be no direct impacts and less than significant indirect impacts on special-status species as a result of the operation of the cantonment and housing at Barrigada. Impacts would be avoided and minimized through the implementation and management of appropriate BMPs and access limitations to military personnel and their dependents as described for the resources above. There would be no impacts on special-status species from stormwater, sedimentation, or other non-point source pollution from operational activities due to the implementation of appropriate LID and BMPs.

Increased dive boat operations have the potential for increased turtle harassment and strikes. However, because of the mobility of sea turtles combined with the protective measures anticipated to be in place (i.e., by dive boat operators and the DON), such increased recreational activities may result in less than significant impacts to sea turtles. While sea turtles may be disturbed by increased recreational activity, potential impacts would be short-term and minimal. Any such impacts to the sea turtle population would be reduced in intensity from the previously proposed action evaluated in the 2010 Final EIS.

Marine Conservation Areas

There are no marine conservation areas near Barrigada; therefore, there would be no impacts to marine conservation areas as a result of the operation of Alternative D.

4.4.10 Cultural Resources

4.4.10.1 Affected Environment

The following discussion summarizes previous cultural resources studies and known historic properties and other cultural resources within the area of potential cultural resource impacts associated with Alternative D. The discussion below addresses historic properties, as defined in the NHPA, and other cultural resources as defined under NEPA. The discussion refers to the terms direct effects and indirect effects to historic properties as defined under the NHPA, and impacts to other cultural resources as defined under NEPA (see Section 3.10.3.2). The section is organized to address cultural resources for the cantonment/family housing, followed by discussion of the same resource types for off-site utilities and school expansions associated with this alternative. If this alternative is selected for implementation, the information presented here would be augmented by reviews consistent with the 2011 PA, which provides overall NHPA Section 106 compliance and addresses other cultural resource issues. Refer to Section 3.10 for a detailed description of the 2011 PA. Additionally, some built properties in this section are covered
by Program Comments executed by the ACHP, which resolve Section 106 responsibilities for certain DoD facilities. See Chapter 3, Section 3.10 for more information on definitions and procedures.

Barrigada is located on the northeastern side of Guam and includes portions of both Air Force Barrigada and Navy Barrigada. The site supports a large antenna field developed around an active transmitter facility, which was originally constructed in the late 1940s. A portion of the area is leased to the Guam Army National Guard for small-unit tactics and land navigation training. In the 1950s, the DON constructed new, permanent military facilities including personnel housing, communication centers, and bases. Alternative D would consist of construction and operation of administrative and housing areas, community support facilities (e.g., schools, child development center, community center), and associated utilities (see Figure 2.4-10 in Chapter 2 of this SEIS).

The affected environment for cultural resources associated with Alternative D is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 12: Cultural Resources, Section 12.1.3.2: Barrigada, pages 12-21 to 12-23). This description of the affected environment provided here has been updated with new information from recent archaeological and architectural investigations supporting this SEIS and other projects. To determine whether information is from an existing reference (such as the 2010 Final EIS or other cultural resource studies) or collected during in-fill studies conducted in support of this SEIS, refer to dates in the reference column in each table for the archaeological sites. Information for the architectural resources was derived from iNFADS.

Surveys conducted to support the 2010 Final EIS included the PDIA for Alternative D. Those and other previous investigations included intensive archaeological surveys (Athens 2009; Dixon et al. 2011a), architectural overviews (Craib and Yoklavich 1996; Mason Architects and Weitze Research 2010), potential TCP studies (Griffin et al. 2010), and oral histories (Welch 2010). An archaeological survey of 98 acres (40 ha) and an architectural survey of buildings on the Nimitz Golf Course were conducted for this SEIS (Dixon et al. 2014). Recently, previously unknown archaeological materials were discovered within the Nimitz Golf Course (Bulgrin 2014). Consultation on treatment of these resources is in process. These investigations provide a comprehensive inventory of cultural resources occurring within the Alternative D PDIA.

In addition to the primary cantonment/family housing areas, on-site utility corridors associated with Alternative D would be located along the easements of Routes 3, 16, and portions of Route 8 (see Figure 2.4-11). A reconnaissance level survey was conducted for the proposed utilities adjacent to Route 3 and Route 16 to north Barrigada in 2010 and no archaeological sites were recorded (Dixon and Walker 2011). Unsurveyed portions of Route 16 are highly developed and primarily paved, and unlikely to have buried cultural resources (based on literature review of available studies in the area indicating that geologic context lacks the depth typically associated with intact deposits below the level of disturbance from development and pavement).

All cantonment alternatives would include construction of off-site utilities along Routes 1, 3, and 9, a water well field at AAFB, and expansion of two schools at Naval Base Guam and AAFB (see Figure 2.4-14). Assessments of potential impacts to cultural resources from construction of utilities along road right-of-ways are based on a reconnaissance survey of portions of the area in 2010 (Dixon and Walker 2011) and a literature review of previous surveys and historic development in the area. Assessments of impacts to cultural resources from the development of a water well field and from the two school expansions are based on the in-fill surveys conducted in support of this SEIS (Dixon et al. 2014)
Based on data from previous surveys of the proposed cantonment/family housing area and utility corridors, Table 4.4.10-1 lists 16 known archaeological sites or locations with archaeological materials within the Alternative D PDIA on Barrigada. No known NRHP-eligible or listed archaeological sites are located in the PDIA for Alternative D. Thirteen locations with Late Period pottery were recently recorded in disturbed areas of the Nimitz Golf Course. None of these locations have been evaluated for listing in the NRHP.

Legend: GHPI = Guam Historic Properties Inventory; NRHP = National Register of Historic Places; NA = not applicable.
Notes: †Not all sites recorded within the project areas have received official GHPI numbers, although they have been documented as part of previous surveys.
*Map numbers are from Welch et al. (2009).
**Revised to match Guam GHPI forms dated May 28, 2014.
Two archaeological sites, 66-08-2714 and T-H-1, have been identified within the potential impacted area for Alternative D on-site utility corridors. These sites are considered not eligible for listing in the NRHP. A potential TCP, Mount Barrigada, is located at the northern end of the Barrigada site. There are 44 architectural properties, constructed between 1948 and 2007 within the cantonment/family housing PDIA (Table 4.4.10-2). These buildings and structures include dormitories, support facilities, and recreation facilities. Thirty-seven buildings and structures have been determined ineligible for listing in the NRHP (Dixon et al. 2014); including 31 buildings that are less than 50 years old and do not meet the exceptional significance threshold required under NRHP Criteria Consideration G. Five buildings are bachelor housing (dormitories and support facilities) covered under the Program Comment for Cold War Era Unaccompanied Personnel Housing (ACHP 2006; see Chapter 3.10.3 for more information on the Program Comment). Two buildings and structures in the PDIA are facilities that are greater than 50 years in age that have not been evaluated. If Alternative D were selected, any potentially affected unevaluated properties would be evaluated under the procedures identified in the 2011 PA. The 2011 PA includes procedures for the identification of historic properties, as specific projects are developed, through consultation with the Guam SHPO and the public.

In addition to the cantonment/family housing, and utility corridor areas, Alternative D would include construction of off-site utilities, a water well field, and expansion or construction of two schools. Cultural resources are similar to those discussed under Alternative A. These include the presence of 9 NRHP-eligible archaeological sites and 15 sites not considered eligible for listing in the NRHP (see Alternative A, Table 4.1.10-4). As under Alternative A, 1 structure within the well development area on AAFB is eligible for listing in the NRHP, 4 structures are not eligible, and 6 structures are unevaluated (see Alternative A, Table 4.1.10-5). No architectural properties or TCPs have been identified within the off-site utilities PDIA.
The proposed Andersen Middle School expansion and the DoDEA High School construction are common to Alternatives A, B, and D. The proposed Andersen Middle School project area contains three structures at AAFB, which are not eligible for listing in the NRHP (see Alternative A, Table 4.1.10-5). No archaeological sites or TCPs have been recorded in this area.

4.4.10.2 Environmental Consequences

Construction

Construction activities associated with Alternative D may adversely affect historic properties. Final determinations of effect would occur under the 2011 PA. Following is a discussion of potential adverse effects for purposes of this analysis. Excavation and soil removal associated with building and utilities construction would not adversely affect any known NRHP-eligible archaeological sites (see Table 4.4.10-1); however, 13 locations containing archaeological materials could be adversely affected, if they are determined eligible for listing in the NRHP.

Construction at Barrigada would also require the demolition of the 44 buildings mentioned above (see Table 4.4.10-2). Of these 44 buildings, 37 buildings have been determined ineligible for listing in the NRHP, 5 are covered under the Program Comment for Cold War Era Unaccompanied Personnel Housing (ACHP 2006), and 2 are unevaluated. The Program Comment resolves NHPA Section 106 requirements for demolition of these five buildings. As the 37 buildings are not eligible for listing in the NRHP, their demolition under Alternative D would be consistent with a finding of no historic properties affected. Consistent with the 2011 PA, final determinations of eligibility, including the two unevaluated architectural properties and the 13 locations with archaeological materials, and assessment of effect would be completed in conjunction with project-specific reviews, if this alternative is developed. Excavation and soil removal associated with the construction of off-site utilities and expansion of two schools could adversely affect 9 known NRHP-eligible archaeological sites (see Alternative A, Tables 4.1.10-4 and 4.1.10-5) and 1 NRHP-eligible structure. Six structures that are unevaluated could also be adversely affected by construction.

The proposed Andersen Middle School expansion would require the demolition of three structures that are not eligible for listing in the NRHP (see Alternative A, Table 4.1.10-6).

In addition, construction at Barrigada has the potential to directly impact culturally important resources that are not historic properties, but may be considered under NEPA. The project would require the removal of limestone forest where culturally important natural resources may be present. The 2011 PA contains measures for coordinating with the SHPO and concurring parties to contact traditional natural healers, herbal practitioners, and traditional artisans regarding identification and disposition of these important resources (see 2010 Final EIS, Volume 2: page 2-10; Volume 9, Appendix G, Chapter 4).

Operation

Operations associated with Alternative D would not directly affect any historic properties or impact other resources of cultural importance. Similarly, operations under this alternative would result in no indirect adverse effects. Increased population in this area would not adversely impact Mount Barrigada since the operations would not limit access to the property, or adversely impact its association with Chamorro legends.

Summary of Impacts and Potential Mitigation Measures

Implementation of Alternative D could cause direct, adverse effects to 9 known NRHP-eligible sites, which is the smallest number of effects compared to any of the alternatives. Refer to Section 4.7, Table
4.7-1 for a comparison of cultural resources impacts and potential mitigation measures for each
cantonment/family housing alternative. Construction could also affect 13 locations with archaeological
materials and 8 buildings that have not been evaluated for listing in the NRHP.

Direct impacts could occur to natural resources of cultural importance as a result of limestone forest
removal. The 2011 PA includes measures to coordinate with SHPO and concurring parties to address
appropriate treatment of these resources.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA
Section 106 requirements for the overall relocation action. Broadly, the 2011 PA includes processes to
share information, consider views of the public, and develop mitigation measures when historic properties
may be adversely affected. The 2011 PA provides measures for mitigating adverse effects to NRHP-
eligible or listed archaeological sites, consulting on new projects and initiating additional identification
efforts, and resolving impacts due to loss of access to culturally important natural resources. To the
degree possible, direct and indirect impacts to historic properties and other resources of cultural
importance would be avoided or minimized during the planning process. Consultation under the 2011 PA
would address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not
possible, Table 4.4.10-3 presents potential mitigation measures to resolve adverse effects to historic
properties and reduce impacts to cultural resources from the implementation of Alternative D. With the
implementation of these measures and processes as outlined in the 2011 PA, it is expected that significant
direct and indirect impacts due to construction, as defined under NEPA, would be reduced to a level
below significance.

Impacts to Other Cultural Resources (NEPA)

<table>
<thead>
<tr>
<th>NHPA Effects</th>
<th>Mitigation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Potential direct adverse effects to 10 historic properties—9 NRHP-eligible archaeological sites and 1 NRHP-eligible structure</td>
<td>Consistent with the 2011 PA, data recovery is the standard mitigation for historic properties that are strictly archaeological in nature. Accordingly, the DON will submit a mitigation plan to the SHPO, consult with other PA Signatories and Concurring Parties if requested, and submit data recovery reports for SHPO review prior to finalizing mitigation reports. Mitigation also includes preparation of public education and interpretation materials in English and Chamorro using the information developed or data recovered to create a summary of the work completed and a statement regarding the mitigated site’s significance to the regional culture. Additional mitigation would include enforcement of construction contract stipulations and GHPI data form updates as required by the 2011 PA.</td>
</tr>
<tr>
<td>Undetermined effects to 13 unevaluated archaeological locations and 8 unevaluated buildings</td>
<td>If this alternative is selected in the ROD, unevaluated properties that may be affected would be evaluated consistent with the 2011 PA. If determined eligible for listing in the NRHP, appropriate mitigation measures would be developed to resolve any adverse effects.</td>
</tr>

4.4.11 Visual Resources

4.4.11.1 Affected Environment

A list and description of visual resources at Barrigada is contained in the 2010 Final EIS (Volume 2, Chapter 13: Visual Resources, Section 13.1.2.3: Affected Environment, page 13-32). The Barrigada area is relatively flat and varies from mowed grassland to dense, natural vegetation. Rural and suburban lands surround the Navy and Air Force Barrigada site. Due to the relatively flat topography and moderate to heavy vegetation, the surrounding community of Barrigada has limited views into the Navy and Air Force Barrigada site. One exception is the view from Mount Barrigada, just north of the potential Barrigada cantonment and housing area.

4.4.11.2 Environmental Consequences

Off-base housing was proposed and analyzed with two alternatives in the 2010 Final EIS. The proposed development at Barrigada reviewed in this SEIS would involve both housing and cantonment development. The visual impacts would be greater with this enhanced development proposal.

Construction

Because there is less development associated with the proposed action due to a smaller number of Marines and dependents being relocated, the degree of impacts would be less than those described in the 2010 Final EIS (Volume 2, Chapter 13: Visual Resources, Section 13.2.2: Environmental Consequences, pages 13-65 to 13-67). The direct impacts to existing public views would be short-term, as they would be caused by the presence of construction equipment, and would cease to continue after construction. Therefore, there would be minimal direct and short-term impacts on visual resources.

Operation

Similar to the 2010 Final EIS analysis, development is proposed contiguous to various public roadways, including Route 15 and Route 16. With the construction of the cantonment and the family housing, the visual characteristic would be altered to a more urban appearance. Although the degree of what would be built is much greater than proposed in the 2010 Final EIS, the resulting direct impacts to the visual element would be long-term, but less than significant, since the visual character of the base would not be drastically altered.

4.4.12 Ground Transportation

4.4.12.1 Affected Environment

The affected environment under Alternative D includes transportation facilities internal to the site (on-base roadways and intersections) and entry control facilities. This section discusses existing conditions and assesses how the construction and operation of Alternative D would potentially affect conditions for roadways, transit facilities, and pedestrian and bicycle facilities on-base. Impacts to off-base (external) roadways and intersections are summarized in Section 6.1 of this SEIS.

Roadway Network

Gated access points are provided at Route 16 and Sabana Barrigada Drive. Route 15 forms the eastern bounding edge and Route 16 forms the western bounding edge of the Navy Barrigada parcel, which abuts the northeastern edge of the Air Force Barrigada parcel. Route 15 forms the southern edge of the Air Force Barrigada parcel. The primary point of entry into the Air Force Barrigada site is from the south side, where an unnamed access street intersects Route 15. The access point is located at the intersection of Chada Street and Route 15. Chada Street is an off-base roadway that intersects Route 15 from the
The Air Force Barrigada parcel could also potentially be accessed from the western side, from Route 10, by heading into Lalo Street.

**Transit Network**

There is no existing transit service on Barrigada. The GRTA operates fixed route and paratransit service. The Redline, servicing Hagåtña, Mangilao, Barrigada, and Toto, is the nearest fixed route bus line, and operates at a distance of approximately 1.0 miles (1.6 km) from Barrigada. Paratransit service is provided to all ADA-eligible certified passengers, by providing transportation to the nearest fixed route.

**Pedestrian and Bicycle Network**

There are no dedicated pedestrian or bicycle facilities on or near Barrigada. Typically, the outside lane or shoulder, which is generally unpaved, functions as the pedestrian/bicycle space.

**Environmental Consequences**

Potential ground transportation impacts addressed in this section are limited to elements of the proposed action that could affect on-base (internal) roadways. Potential ground transportation impacts to off-base (external) roadways are addressed in Section 6.1 of this SEIS.

**Construction**

Potential construction impacts generated by the proposed action at Alternative D would be similar to Alternative A (Section 4.1.12.2). Potential short-term, direct impacts to ground transportation resources from construction would be reduced to less than significant levels with implementation of appropriate work zone traffic management strategies and BMPs. Therefore, construction of Alternative D would have less than significant short-term, direct impacts to on-base (internal) roadways.

**Operation**

**Roadway Network**

As currently proposed, Alternative D would be accessible via a new Main Gate and a new Commercial Gate located at Route 15 in the southern part of the site, as well as a new Residential Gate in the northern part of the site at Route 16. The buildings and facilities at Alternative D would be grouped into three contiguous development areas.

The proposed on-base (internal) roadway network hierarchy for Alternative D was determined based on the conceptual development plan and layout of the cantonment/family housing area, and takes into account the capacity required to accommodate the expected travel demand on the facilities. The proposed on-base (internal) roadway network hierarchy diagram for Alternative A is included in an Appendix to this SEIS.

An arterial four-lane roadway would traverse the site from the proposed new Main Gate on the south to the proposed new Residential Gate on the north end of the site. This roadway would be expected to carry the heaviest traffic volumes, including civilian employee trips from off-base to/from work locations, as well as trips by military personnel to/from off-base locations. A shorter east/west arterial roadway is proposed to carry traffic from the north/south arterial to the live/work and QOL areas at the cantonment area in the southern part of Barrigada. Collector roadways would distribute traffic within the core area and would provide much of the access to individual buildings, operational areas, and parking facilities. Residential two-lane roadways located within the family housing area would provide access to individual residences.
Under any of the proposed cantonment/family housing alternatives, construction of new on-base (internal) roadway facilities and entry control facilities would be required. The proposed action includes construction of on-base (internal) roadways and entry control facilities that would be implemented by the DoD. On-base (internal) roadways and entry control facilities for Alternative D, include, but are not limited to, the following:

- A new Main Gate would be constructed on Route 15, and would provide direct access to the cantonment area at the south end of the site.
- A new Commercial Gate would be constructed on Route 15, and would provide direct access to the cantonment area for commercial vehicles.
- A new Residential Gate would be constructed on Route 16, and would provide direct access to the family housing area at the north end of the site.
- A four-lane arterial roadway would run from the new Main Gate on Route 15 to the new Residential Gate on Route 16.

All on-base (internal) roadways and intersections have been designed with the capacity required to accommodate the expected travel demand on the facilities. Specifically, the facilities are designed to operate at acceptable LOS (LOS A, B, C, D, or E) under future year (Year 2030) conditions with the proposed action. The proposed action would not result in a significant long-term, direct impact to on-base (internal) roadways or intersections because the proposed action would not:

- For roadway segments and intersections - cause a roadway segment or intersection operating at acceptable LOS (LOS A, B, C, D, or E) to degrade to unacceptable LOS F.
- For roadway segments - add 5% or more to the total directional peak hour volume (measured in passenger car equivalents) and result in unacceptable LOS F.
- For intersections - add 50 or more peak hour trips (measured in passenger car equivalents) and result in unacceptable LOS F.

**Entry Control Facilities**

The operations of the proposed entry control facility are controlled, or dictated, by both the traffic demand and the vehicle processing speed at the security check point. The methodology and assumptions utilized to evaluate operations and potential for queuing at the entry control facilities is stated in Section 4.1.12.1.

**Transit Conditions**

A circulator shuttle system is being considered to address the internal transportation needs of the cantonment. The shuttle system would transport Marine Corps personnel around the cantonment area and provide service to on-base destinations. On-base shuttle service could also coordinate with the GRTA bus system to provide service to popular off-base destinations as well.

The proposed action would not result in a significant long-term, direct impact to transit, because the proposed action would not:

- Substantially increase traffic hazards to transit due to a design feature (e.g., sharp curves or dangerous intersections) that does not comply with applicable design standards.
- Fundamentally conflict with adopted policies, plans, or programs regarding public transit; or otherwise decrease the performance or safety of transit facilities.
Pedestrian and Bicycle Conditions

Bicycle and pedestrian facilities would be included in the construction of new roadway facilities. Bicycle and pedestrian paths and facilities are integrated into the on-base transportation network as a means to improve mobility and safety of non-motorized traffic. The proposed bicycle and pedestrian network diagram for Alternative D is provided in an Appendix to this SEIS.

The proposed pedestrian and bicycle network includes an extensive multi-purpose trail network along most major roadways. An enhanced pedestrian sidewalk would connect community support and QOL facilities within the cantonment area. All residential streets would be constructed with sidewalks on both sides of the street. A jogging/biking trail would circumnavigate the family housing area, connect to the cantonment area, and continue around the periphery of the cantonment area.

The proposed action would not result in a significant long-term, direct impact to pedestrians or bicycles, because the proposed action would not:

- Substantially increase traffic hazards to pedestrians or bicycles due to a design feature (e.g., sharp curves or dangerous intersections) that does not comply with applicable design standards.
- Fundamentally conflict with adopted policies, plans, or programs regarding bicycle or pedestrian facilities, or otherwise decrease the performance or safety of such facilities.

4.4.13 Marine Transportation

4.4.13.1 Affected Environment

The affected environment for marine transportation under Alternative D is the same as described in Section 4.1.13.1 for Alternative A.

4.4.13.2 Environmental Consequences

The environmental consequences for marine transportation under Alternative D would be the same as described in Section 4.1.13.2 for Alternative A.

4.4.14 Utilities

4.4.14.1 Affected Environment

This section includes information related to existing electrical, potable water, wastewater, solid waste, and IT/COMM utilities as they apply to the Alternative D.

Electrical Power

The existing electrical utility for Alternative D consists of power distribution systems serving the former golf course, antenna field, and other existing facilities. This existing infrastructure is quite minimal and is concentrated in the northern area of Barrigada, where the National Guard and Army Reserves have their facilities. The power being supplied to this area comes from the GPA transmission and generation system. The situation and condition of these utility systems is unchanged from the 2010 Final EIS (Volume 6, Chapter 3: Utilities, Section 3.1: Affected Environment, page 3-5).

Potable Water

The existing potable water utility pertaining to Alternative D consists of a water supply well for irrigation, and DoD water distribution systems serving the former Nimitz Golf Course and other existing facilities. This utility system remains basically unchanged from the description provided in the 2010 Final EIS (Volume 6, Chapter 3: Utilities, Section 3.1: Affected Environment, page 3-10). In January 2013, the
Admiral Nimitz Golf Course was shut down and closed operations, so water usage by that facility has ceased. There is an existing 3.0 MGD (11.4 MLd) ground-level concrete water storage tank at the north area on Mount Barrigada that is part of the DoD water system.

Existing facilities at Barrigada are served solely by the DoD water system. The overall affected environment of the DoD and the GWA potable water systems is the same as described under Alternative A in Section 4.1.14.1 under Potable Water.

Wastewater

The GWA compliance background discussed in Alternative A Section 4.1.14.1 is the same for Alternative D. The current major wastewater compliance requirements for GWA are covered under a 2011 court order, a USEPA NEIC inspection conducted in 2012, and 2013 NPDES permits requiring treatment upgrades for the Northern District WWTP and Agaña WWTP.

The affected environment for wastewater utilities associated with Alternative D is described in the 2010 Final EIS (Volume 6, Chapter 3: Utilities, Section 3.1: Affected Environment, pages 3-26) and updated in Section 4.1.14.1.

Alternative D has an existing wastewater collection system serving Navy Barrigada. The existing system includes approximately 13,000 feet (3,962 m) of gravity sewer lines ranging from 6 to 8 inches (15 to 20 cm) in diameter. The wastewater generated from Navy Barrigada is conveyed to the Agaña WWTP through the GWA collection system.

A capacity assessment of the GWA collection system was conducted in the 2007 Water Resource Master Plan. The assessment included flow and rainfall monitoring, hydraulic modeling, model calibration, and sewer capacity evaluations. Capacity assessment of the collection system was assessed for the year 2025. For the Agaña WWTP service area, the estimated wastewater projection was 9.1 MGD average daily flow by the hydraulic sewer model, which is reasonably close to the projected wastewater flow for the proposed action. The modeling results for the Agaña WWTP service area indicated the pipe segments along Route 10 and Route 8 were adequately sized. However, the model results did indicate under-sized pipe segments along Route 1, upstream of the Agaña WWTP. The GWA has taken steps to alleviate the capacity limitations to the central wastewater system, particularly with the upgrades to pump stations and more periodic sewer cleaning and inspections, as required by a 2011 Court Order. Other ongoing and future GWA Capital Improvement Plan projects include the Central Inflow and Infiltration Analysis and Sewer System Evaluation Survey, and the Wastewater Collection System Replacement/Rehabilitation Program.

The GWA is also in the process of updating the hydraulic sewer model used in the 2007 Water Resource Master Plan. The updated model could then be used to indicate where system limitations and failures are located, as well as where maintenance and/or replacement of piping and pump stations should be targeted. Comprehensive visual inspections of the collection systems and a hydraulic model are critical first steps in assessing the condition of the collection system. Undertaking these first steps would allow critical prioritization of maintenance and upgrades to the system, and necessary validation of the GWA Capital Improvement Plan for the collection systems. Until this is done, the DoD can only assess indirect impacts qualitatively.

The island-wide GWA wastewater collection system has undergone periodic inspections and cleaning as required under the 2011 Court Order. In an effort to meet compliance with the 2011 Court Order, the GWA is also proceeding with inflow and infiltration analyses, and sewer system evaluation surveys for
the central and southern collection systems and has added on the northern collection system as described in Section 4.1.14.1.

As required by the 2011 Court Order, primary treatment upgrades at the Agaña WWTP have been completed as of March 2014. The Agaña WWTP has a design capacity of 12 MGd (45.4 MLd). However, with the issuance of a 2013 NPDES permit, the plant currently has no operational ability to meet the new treatment discharge limits.

The Northern District WWTP would receive direct wastewater flows from Alternative D from facilities located on AAFB. Similar to the Agaña WWTP, the Northern District WWTP has a design capacity of 12 MGd (45.4 MLd). The 2013 NPDES permit requires meeting the secondary treatment discharge limits and Guam Water Quality Standards, including those for nutrients, which the plant cannot meet until it is upgraded. Thus, both WWTPs are currently in a state of non-compliance with the 2013 NPDES permits.

The Southern GWA WWTPs Agat-Santa Rita, Baza Garden, and Umatac-Merizo, are described in Section 4.1.14.1.

Solid Waste

The existing solid waste infrastructure has changed since the publication of the 2010 Final EIS. Solid waste continues to be collected and taken off-site for disposal. Currently, DoD contractors pick up waste from the Barrigada site and take it to the Harmon Transfer Station for disposal at the Layon Landfill. Other wastes not accepted by the Layon Landfill can be disposed at either AAFB or Naval Base Guam Apra Harbor facilities. The DON is currently coordinating with the GEPA regarding the status of the MSW landfill permit for the Naval Base Guam Landfill. The Solid Waste Working Group consisting of the DoD, GEPA and USEPA was established to coordinate and resolve landfill permitting issues, as well as other solid waste issues on Guam.

Information Technology and Communications

The existing IT/COMM infrastructure at Barrigada includes existing DoD telecommunication lines serving existing facilities, including the antenna field to the east of the proposed family housing area. There is no existing IT/COMM utility in the proposed cantonment area at Barrigada.

4.4.14.2 Environmental Consequences

The assessment of impacts associated with utilities assumed the implementation of sustainability strategies as described in Section 8.6, Sustainability and Smart Growth. These strategies include measures to achieve federally mandated levels of energy use reduction, water use reduction, waste reduction, and total energy from renewable sources.

Electrical Power

Based on the load projections for both the cantonment area and family housing, no upgrade would be required to the GPA’s generating capacity, since the total load increase is within the capacity of their generating plants. However, upgrades to the existing 34.5 kV power transmission lines would be required to stay within operating tolerances. The current electrical power system at Barrigada is not capable of meeting the increased demand from the proposed Marine Corps relocation. Thus, Alternative D includes an expanded electrical power distribution system with additional power feeds from the GPA as described in Section 2.4.4.4. This electrical power distribution system has been developed to handle all system demands currently in existence for areas served by the current local power distribution system, in addition to increased demands from the proposed action. Thus, there would be no long-term adverse direct
environmental impacts to the current power customers, and only potentially short-term power outages during construction of the expanded system.

Impacts to the island-wide GPA power system under Alternative D would be the same as for Alternative A, as described in Section 4.1.14.2. In addition, the existing 34.5 kV transmission system from Guam Airport Authority Substation to the existing Barrigada Substation would require upgrading. The proposed new substation for the cantonment/family housing area at Barrigada would be connected to this upgraded transmission system, providing a double feed option for electrical power security.

Therefore, the short- and long-term, direct impacts to the power system would be less than significant, both during construction and in operation.

**Potable Water**

The existing water system within the affected environment at Barrigada does not have the supply capacity or sufficient distribution network to handle the demand from the proposed development. The current water system for existing facilities would remain in service, but be integrated with the proposed expanded water system for operational efficiency. The proposed potable water distribution system for Alternative D as described in Section 2.4.4.4 has been developed to handle all system demands currently in existence for areas served by the current local water distribution system, in addition to the increased demand from the proposed action. Thus, there would be no adverse long-term, direct environmental impacts to the current DoD water customers, and only the potential for short-term water outages during construction of the expanded system. With careful planning these potential outages would be minimized.

**DoD Potable Water System**

Potential direct long- and short-term impacts to the DoD system would be the same for Alternative D as for Alternative A, as described in Section 1.14.1.2. Some additional required upgrades to the existing off-base transmission mains along Route 1 and Route 16 would be needed to convey the required water supply to Barrigada. The construction of the upgrade could require short-term outages during construction but would be installed adjacent to the existing main and switched over in phases to minimize water service interruptions to current customers. With careful planning these potential outages would be minimized.

**GWA Potable Water System**

Potential impacts to the GWA system would be the same for Alternative D as for Alternative A, as described in Section 4.1.14.2. The long- and short-term direct impacts to the GWA potable water system from the proposed action Alternative D would be less than significant, both during construction and in operation.

**NGLA Water Extraction**

Potential short- and long-term impacts to the NGLA, and potential mitigation measures of impacts, would be the same for Alternative D as for Alternative A, as described in Section 4.1.14.2. Thus, the localized direct impact to the NGLA is considered significant, but the impact to the overall NGLA would be less than significant. Potential mitigation measures for impacts to the NGLA would be the same as those discussed in Section 4.1.14.2 for Alternative A.

**Wastewater**

Wastewater generated from Alternative D would be collected, conveyed to, treated, and disposed of at the Agaña WWTP for facilities located at Navy Barrigada, and at the Northern District WWTP for facilities
located at AAFB. Proposed facilities located on AAFB would have similar environmental consequences as described in Alternative A in Section 4.1.14.2. Baseline and projected average and total monthly flows for the Northern District WWTP and Agaña WWTP are shown in Tables 4.4.14-1 and 4.4.14-2.

### Table 4.4.14-1. Northern District WWTP Wastewater Flows

*Notes: ¹Direct includes only “project, or cantonment/family housing, and new incoming Marine Corps personnel.*

²Indirect includes non-project, other DoD, and induced impacts, including ACE.

The existing wastewater collection system at Barrigada cannot handle the increase in demand from the proposed action. The proposed wastewater collection system for Alternative D, as described in Section 2.4.4.4, has been developed to be independent of the existing Navy Barrigada wastewater collection system and should be able to handle the projected flows from the proposed action. The proposed wastewater collection system would extend off-base and connect to the GWA collection and conveyance system on Route 10. Proposed off-base improvements would include refurbishment of an existing GWA pump station, or construction of a new pump station and a new force main to tie into the GWA collection system along Route 8. Ownership of new off-base infrastructure connecting the proposed wastewater system to the GWA collection system would be given to the GWA.

The Agaña WWTP and the Northern District WWTP cannot meet permit requirements for treatment of the projected maximum monthly wastewater flows derived from the proposed action and other sources. Therefore, they are unable to meet the current treatment requirements. Increasing the wastewater flow to a non-compliant treatment plant by the amounts shown in Tables 4.4.14-1 and 4.4.14-2 would be a significant impact. The DoD would assist GWA in identifying funding from federal agencies such as the DoD OEA, the DOI, and others for upgrades to the Northern District WWTP. Wastewater flow to Agaña WWTP from the preferred alternative is deemed negligible. Under this alternative, the increased wastewater flows to Agaña WWTP from the proposed action would be from indirect sources, from induced civilian growth, and would be less than 1% of the total projected flow. Therefore, consistent with impact assessment criteria in the SEIS, a less than significant impact to the wastewater flow to Agaña
WWTP is anticipated from the proposed action. It should be noted that the construction workforce would likely be located within the Northern District WWTP area under the preferred alternative.

The FY 2014 NDAA directed the Secretary of Defense to convene the EAC in part to develop an implementation plan that will address public infrastructure requirements necessary to support the preferred alternative. The implementation plan will detail descriptions of work, costs, and schedules for completion of construction, improvements, and repairs to Guam public infrastructure affected by the realignment, including improvements and upgrades to the Guam wastewater system. Section 8102 of the FY 2014 Consolidated Appropriations Act (Public Law No. 113-76) appropriated $106.4 million to the Secretary of Defense, acting through the OEA, for civilian water and wastewater improvements on Guam. These funds will remain available until expended.

The required improvements to treatment from the newly issued permits need to have an agreed upon timeline for implementation. Obtaining funding, performing design and construction, and bringing the new portions of the WWTP into operational status is a time-consuming endeavor and must be given a reasonable length of time for proper implementation. Ultimately, this is dependent upon the GWA and the USEPA reaching an agreement on a suitable implementation timeline.

The GWA southern WWTPs (Agat-Santa Rita WWTP, Baza Gardens WWTP, Umatac-Merizo WWTP, and Inarajan WWTP) would not receive direct DoD wastewater flows from the proposed action, but would be indirectly affected to a small degree by the proposed action from indirect wastewater flows from the induced civilian growth as well as forecast organic civilian growth in the region. The increased wastewater flow from indirect impacts from the proposed action to the four southern GWA WWTPs is estimated to total a maximum monthly flow of 0.02 MGd (0.08 MLd); a small percentage of the total capacity of the plants. Upgrades to the GWA southern WWTPs are requirements under the 2011 Court Order, and planning and design are in progress. Due to the small flow increases from the proposed action and the induced civilian growth, the impact to the southern WWTPs would be less than significant.

During construction of the proposed action less than significant impacts would result from potential service outages and sewage spills. The impacts for Alternative D are similar to those assessed for Alternatives A, B, C, and E. These impacts would be minimized through compliance with the DON’s utilities outage procedures and implementation of BMPs such as; coordination with utility providers and permitting agencies, and prior to excavation identifying existing underground utility lines through utility research, toning, or potholing. Other potential BMPs may include constructing sewers during low flow periods, by-pass pumping, and having pump trucks on stand-by.

Other long-term operational impacts related to implementing the proposed action would include increases to power needs; operator staffing and training; sludge handling; fats, oils, and grease; and industrial wastewater. Potential mitigation measures to operation impacts may include the Marine Corps contributing to the GWA revenues for operations and maintenance as a new rate paying customer; payments of service development charges; the implementation of an on-base program to control fats, oils, and grease with grease traps; and pretreating industrial wastewater with oil-water separators or other applicable pretreatment systems. Thus, long-term, direct impacts during operations would be mitigated to less than significant.

The significance of wastewater impacts for Alternative D would be significant but mitigable for both the Agaña and Northern District WWTPs and their collection systems.
Solid Waste

The solid waste infrastructure for Alternative D as described in Section 2.4.4.4 has been developed to meet the requirements for the proposed action. The environmental consequences for the solid waste infrastructure associated with Alternative D are similar as for Alternative A, as provided in Section 4.1.14.2 under Solid Waste. In the case of Barrigada; however, the C&D debris would mainly consist of concrete (from the planned demolition of the existing buildings at the former Nimitz Golf Course) that would be crushed and used as lower-grade aggregate.

The new Layon Landfill is designed to account for the level of MSW projections from the 2010 Final EIS. Therefore, it has the capacity to accommodate the projected MSW for the reduced levels of the current proposed action. The reduction in the generation of solid waste under the current proposed action versus the 2010 proposed action is a beneficial effect, as this increases the life of the existing Layon Landfill. Therefore, there would be less than significant long-term direct and indirect impacts to the solid waste resources on Guam for Alternative D, both during construction and operation.

The DON proposes to explore ways to resolve key solid waste issues, specifically the status of the Naval Base Guam Landfill permit and handling of special wastes not accepted at Layon Landfill, through the Solid Waste Working Group that was established with USEPA and GEPA on July 24, 2014. During the September 19, 2014 meeting of the Solid Waste Working Group, GEPA indicated that they will formally respond to DON correspondence with regards to issues relative to the Naval Base Guam Landfill. The Layon Landfill and the permitted private hardfill facilities are operating within their regulatory requirements. The proposed action would be in compliance with all applicable GEPA solid waste permit terms and conditions that routinely include specific measures to protect human health and the environment. All other projects on Guam would utilize permitted solid waste management and disposal facilities.

Information Technology and Communications

The proposed IT/COMM infrastructure for Alternative D, as described in Section 2.6, has been developed to meet the requirements for the proposed action. For the proposed cantonment area at Barrigada, there is no existing IT/COMM infrastructure; therefore, there would be no impacts to those users.

For the proposed housing area at Barrigada, there are several existing DoD IT/COMM lines, but no commercial lines. The proposed housing area has been designed around those existing lines using the best available information on their locations. It is possible that these lines could be impacted during construction. Should the locations of these existing lines be different from available information, the lines might require relocation or the proposed development might require revisions to avoid the existing lines.

Additional inter-base IT/COMM connectivity would be required, as described in Section 2.6. This includes the connection between AAFB and the existing Tata cable landing facility in southern Guam, which would require new rights of way along some southern roads, as well as the access road to the Tata facility.

Therefore, long- and short-term direct impacts to existing IT/COMM infrastructure would be less than significant both during construction and in operation.
4.4.15 Socioeconomics and General Services

4.4.15.1 Affected Environment

The affected environment for socioeconomics and general services on Guam is presented for the entire island of Guam and does not vary by alternative. Because the affected environment does not vary by alternative, it is only presented one time, under Alternative A. A full description of the affected environment for socioeconomics and general services is presented in Section 4.1.15.

4.4.15.2 Environmental Consequences

The socioeconomics and general services impacts under Alternative D would be island-wide, direct and indirect, short- and long-term, and would be the same as described under Alternative A in Section 4.1.15. The population change associated with Alternative D would not likely put excessive strain on Guam’s public services and permitting agencies, and the estimated increases in GovGuam tax revenues would likely compensate for any increased demand that would occur. The economic impacts would be beneficial, leading to increased employment and standards of living, and impacts to Guam’s housing stock and availability would not bring about reactionary development, which could have otherwise lead to dislocations in the housing market. There is a potential for sociocultural impacts to occur, but the magnitude of the impacts could vary substantially based on policy and program choices yet to be made on how to address them.

4.4.16 Hazardous Materials and Waste

4.4.16.1 Affected Environment

The current DoD ROI on Guam for hazardous materials and waste in this section includes the Barrigada property proposed for development of the cantonment, the former Nimitz Golf Course and the areas affected by off-site utilities development and DoD school expansions (see Section 2.4.4.6 in Chapter 2). There currently are no hazardous materials storage or hazardous waste accumulation sites located at Barrigada.

Contaminated Sites

Installation Restoration Program Sites

One IRP site, Naval Computer and Telecommunications Station Western Pacific Site 14: Barrigada Golf Course landfill is located on the Barrigada parcel proposed for development under Alternative D (Figure 4.4.16-1). This site is not currently active and land use restrictions may exist for the site. This site is described in detail in the 2010 Final EIS (Volume 9: Appendices, Appendix G: EIS Resource Technical Appendix, Chapter 3: Hazardous Materials and Waste Resources, Table 3.6-3 Summary of Active Navy Environmental Restoration Sites in Central Guam, pages G-3-44 to G-3-49). In addition, the Barrigada Substation is located adjacent to the area proposed for development of cantonment/family housing under this alternative. This site is also a restricted/active IRP site.

Military Munitions Response Program

No MMRP sites were identified on the Barrigada/Nimitz Golf Course parcel proposed for development of cantonment/family housing under Alternative D.
Figure 4.4.16-1
IRP Sites in the Vicinity of Barrigada Cantonment/Housing Alternative D

Source: NAVFAC Pacific 2013
Toxic Substances Management

Currently, there are a few structures located on the portion of Barrigada proposed for development of the cantonment/family housing under this alternative. Any structure constructed prior to 1978 may contain LBP, ACM, and PCBs. Elevated levels of lead and PCBs associated with IRP sites may be present in site soils.

According to USEPA, the parcel is located in an area classified as Zone 1 for Radon, indicating average indoor radon levels of greater than 4 pCi/L.

4.4.16.2 Environmental Consequences

Short-term construction impacts and long-term operational impacts to hazardous materials and waste under this alternative would be similar to those described under Section 4.1.16.2 of this SEIS. Hazardous materials and hazardous waste would be managed as described for AAFB, NWF, and Finegayan in Section 3.16 of this SEIS. Therefore, implementation of Alternative D would result in less than significant direct and indirect impacts to hazardous materials and waste.

4.4.17 Public Health and Safety

4.4.17.1 Affected Environment

Notifiable Diseases

The Affected Environment for notifiable diseases for Alternative D is the same as discussed in Section 4.1.17.1 for Alternative A.

Mental Illness

The Affected Environment for mental illness for Alternative D is the same as discussed in Section 4.1.17.1 for Alternative A.

Operational Safety

To protect the general public from intentional or accidental entry onto Barrigada, locked or manned gates are used where vehicle access is provided and a series of signs warning unauthorized personnel not to enter the area are posted along the perimeter of the installation. Unauthorized personnel are not allowed on the installation at any time.

Barrigada is largely used to support DoD communication high frequency transmitting activities. There is a large antenna field developed around an active transmitter facility. In addition, the Air Force Barrigada property is used to accommodate a NEXRAD weather facility. An EMR hazard safety zone has been established around the transmitter antennas to ensure the safety of workers and the public.

Barrigada also supports field training exercises, military operations on urban terrain training in unoccupied housing units, and EOD/land demolition training. Open areas (former transmitter sites) provide command and control and logistics training; bivouac, vehicle land navigation, and convoy training; and other field activities. Land demolition training for location, excavation, identification, and neutralization of buried land mines involves teams locating inert land mines or Improvised Explosive Devices and then designating the target for destruction. These operations are insulated to an interior location of the installation and are sporadic based on variable training conducted by various branches of the military. Activities are conducted in accordance with SOPs to ensure the safety of both training participants as well as the public.
Environmental Health Effects

Noise

There are no current noise management issues associated with the existing operations at Barrigada. Details regarding current noise conditions at Barrigada are provided in Section 4.4.4.1.

Water Quality

Several water wells are situated within the Barrigada property boundary or are immediately adjacent to the installation. These wells each have a mandated 1,000-foot (305-m) buffer identified as a wellhead protection zone. Within this zone, future activities and development are restricted to ensure contaminants are not introduced in these areas, thus protecting the integrity of the island’s freshwater aquifers. Guam’s freshwater aquifers are susceptible to contamination from surface activities. GEPA requires treatment to ensure water quality meets safe drinking water standards. Section 4.4.2.1 provides details regarding current quality of potable water sources.

Hazardous Substances

Current management practices and contingency plans for the use, handling, storage, transportation, and disposition of hazardous substances associated with Barrigada ensure that exposure to the environment and human contact is minimized.

The IRP focuses on cleaning up releases of hazardous substances that pose risks to the public and/or the environment. The MMRP focuses on identifying and removing MEC. One IRP site is situated within Barrigada. No MMRP sites have been identified on Barrigada. The IRP site includes Naval Computer and Telecommunications Station Western Pacific Site 14 (Barrigada Golf Course Landfill) situated north of the NEXRAD facility. Materials disposed at Site 14 include municipal refuse, possibly waste oil from motor pool activities, and debris generated during construction of the golf course (e.g., trees, shrubs, dirt, rocks).

For Public Works Center Site 14, a Site Investigation was conducted and further investigation was recommended to assess the nature and extent of the identified contamination. The hazardous materials and waste section of this SEIS (Section 4.4.16) provides additional detail for the status of IRP and MMRP sites.

Unexploded Ordnance

The presence of UXO within Barrigada is not known. However, Guam was an active battlefield during WWII. As a result of the occupation by Japanese forces and the assault by Allied/American forces to retake the island, unexploded military munitions may still remain.

Traffic Incidents

The nearest high crash frequency location in the vicinity of the proposed cantonment and housing area at Barrigada is the intersection of Routes 8, 10, and 16 (approximately 1 mile [1.6 km] west of Barrigada). This intersection has been identified by GPD as an intersection with a high frequency of traffic incidents. However, traffic improvements were completed in 2012 in an effort to improve vehicle safety, these improvements included installation of a new traffic signal system that reduced congestion and channelized traffic.
4.4.17.2 Environmental Consequences

Potential direct and indirect impacts on public health and safety from implementation of Alternative D would be similar to those discussed under Alternative A.

Notifiable Diseases

Potential increases in notifiable diseases for Alternative D would be the same as discussed in Section 4.1.17.2 for Alternative A.

Mental Illness

Potential increases in mental illness for Alternative D would be the same as discussed in Section 4.1.17.2 for Alternative A.

Operational Safety

To protect the general public from intentional or accidental entry onto Barrigada, locked or manned gates would continue to be used where vehicle access is provided and a series of signs warning unauthorized personnel not to enter the area would remain posted along the perimeter of the installation. Unauthorized personnel would not be allowed on the installation at any time.

The primary operational activities that would occur within the cantonment and housing area include:

- Administrative, supply, service, and maintenance functions for operational units.
- Base support functions.
- Unaccompanied personnel housing and related support functions (e.g., school, child development center, youth center).
- Training functions (i.e., classroom instruction and non-live fire training).
- Community support functions.

Specific and documented procedures would be in place to ensure the public is not endangered by operations and training activities. Therefore, Alternative D would result in no direct or indirect impacts on public health and safety (resulting from operations and training activities).

Electromagnetic Safety

Use of Barrigada to support cantonment and housing requirements for relocated Marines would be conducted so that new developments are consistent with established EMR hazard zones. Exposure to electromagnetic emissions would be limited by restricting access to emitters through the use of security fencing, posting warning signs, or locking out unauthorized persons in areas, where practical. Because electromagnetic emission sources would be operated in accordance with applicable safety standards and the public would be excluded from entering areas where emission sources are located, potential long-term impacts from electromagnetic emissions on public health and safety would not result in any greater safety risk. Therefore, no direct or indirect impact on public health and safety related to electromagnetic emissions is anticipated.

Construction Safety

Because a health and safety program would be implemented for construction activities and the public would be excluded from entering construction areas, potential short-term construction impacts on public health and safety would not result in any greater safety risk. Therefore, no direct or indirect impact on public health and safety related to construction activities is anticipated.
Environmental Health Effects

Noise

Potential short-term construction and long-term operational noise emissions associated with Alternative D would be similar to those discussed under Alternative A. Enforcement of OSHA guidelines for hearing protection for workers would be the responsibility of the construction contractor. The public would be excluded from entering construction areas. Therefore, short-term construction noise impacts on public health and safety would be less than significant. Long-term operational noise from activities occurring within the cantonment and housing areas would be similar to current noise levels. Therefore, overall direct or indirect impacts associated with noise to human health and safety would be less than significant.

Water Quality

Potential water quality impacts associated with Alternative D would be similar to those discussed under Alternative A. Groundwater withdrawal would likely increase. However, sustainability practices would be implemented to reduce the amount of groundwater needed. The resulting total annual groundwater production would be less than the sustainable yield and monitoring of groundwater chemistry would identify any emerging issues to ensure no harm to the water supply. Water wells on and adjacent to Barrigada have a mandated 1,000-foot (305-m) buffer identified as a wellhead protection zone. Proposed development and operational activities would be conducted in accordance with GEPA guidance and BMPs to minimize the potential for contaminants to be introduced in these areas. Therefore, direct and indirect public health and safety impacts from long-term increased demand on potable water and potential water-related illnesses would be less than significant.

Hazardous Substances

Potential direct impacts from hazardous substances for Alternative D would be similar to those discussed under Alternative A. The use, handling, storage, transportation, and disposition of hazardous substances would be conducted in accordance with applicable hazardous material and waste regulations, and established BMPs and SOPs to ensure the health and safety of workers and the general public is maintained.

IRP investigations and/or remediation activities, as necessary, would continue in an effort to clean up past releases of hazardous substances and receive regulator concurrence that necessary actions have been completed to ensure the safety of the public. Site 14 is within the area potentially available for development of cantonment and housing. However, no building construction is proposed within the landfill area and no off-site population is nearby. Therefore, no health hazards have been identified. Because hazardous substance management and IRP investigative/cleanup activities would be conducted in accordance with applicable regulations and established BMPs and SOPs, no direct or indirect impacts on public health and safety are anticipated.

Unexploded Ordnance

Potential direct impacts from UXO for Alternative D would be similar to those discussed under Alternative A. With the exception of public access provisions outlined through the 2011 PA process (see Section 4.4.10, Cultural Resources), the general public would be excluded from entering construction zones and training areas. To reduce the potential hazards related to exposure to MEC, ESS documentation would be prepared that outlines specific measures that would be implemented to ensure the safety of workers and the public. BMPs would be implemented to identify and remove potential MEC items prior to the initiation of ground-disturbing activities. UXO personnel supervision would occur during earth-
moving activities and MEC awareness training would be provided to construction personnel involved in grading and excavations prior to and during ground-disturbing activities. In addition, the DON provides MEC awareness training to GovGuam and other public representatives allowing access to project sites to facilitate surveys or collection of natural resources or items of cultural significance prior to conducting vegetation clearance. Because UXO would be identified and removed prior to initiating construction activities and construction personnel would be trained as to the hazards associated with UXO, potential direct impacts from encounters with UXO would be minimized and less than significant.

**Traffic Incidents**

Potential long-term traffic incident increases for Alternative D would be similar to those discussed under Alternative A. The overall long-term potential for increased traffic incidents on Guam is small (5% increase [see Section 4.1.17.2]). A high crash frequency intersection is located approximately 1 mile (1.6 km) from the Barrigada Main Gate entrance (Route 8/10/16 intersection). Traffic improvements were completed at this intersection in 2012 in an effort to improve vehicle safety. Improvements included installation of a new traffic signal system that reduced congestion and channelized traffic. New personnel would be alerted to the traffic hazards at this multi-intersection in an effort to raise awareness of the hazards of driving in the area. Because the overall potential long-term increase in the number of traffic accidents as a result of the increase in personnel would be minimal, there would be a less than significant impact on the health and safety of the citizens of Guam (from traffic incidents).

**4.4.18 Environmental Justice and the Protection of Children**

**4.4.18.1 Affected Environment**

As described in Alternative A, Section 4.1.18, the affected environment for environmental justice and protection of children analysis is the entire island of Guam. Therefore, the affected environment for Alternative D is the same as for Alternative A. In addition, Alternative D is located in the northern area of the island, the same region as Alternative A. The villages of Dededo and Yigo are within this region.

**4.4.18.2 Environmental Consequences**

Potential impacts to environmental justice populations under Alternative D would be to noise, recreation, socioeconomics and general services (including health services), and public health and safety.

**Noise**

The potential impacts would be the same as Alternative A.

**Recreation**

Impacts are generally island-wide and would be the same as described for Alternative A.

**Socioeconomics and General Services**

Impacts are generally island-wide and would be the same as described for Alternative A, as would the identified measures to mitigate impacts.

**Public Health and Safety**

Impacts are generally island-wide and would be the same as described for Alternative A, as would the identified measures to mitigate impacts.
4.5 **Finegayan Cantonment/Andersen Air Force Base Housing - Alternative E**

Alternative E is the preferred alternative. Under this alternative, the proposed development and operation of a cantonment area and family housing would occur at Finegayan and AAFB, respectively. Details about this alternative, which was added for the Final SEIS in response to public and agency comments on the Draft SEIS, are provided in Section 2.4.4.5 and the proposed sites are illustrated in Figures 2.4-12, 2.4-13, and 2.4-14.

### 4.5.1 Geological and Soil Resources

#### 4.5.1.1 Affected Environment

Under Alternative E, the affected environment for geological and soil resources is as described for Alternative A and Alternative C (Sections 4.1.1 and 4.3.1, respectively, of this SEIS). In addition, an extensive discussion of the affected environment for geological and soil resources on Guam is provided in the 2010 Final EIS (Volume 2, Chapter 3: Geology and Soils Resources, Section 3.1.2.2 Finegayan, pages 3-15 to 3-16 and Section 3.1.2 North, pages 3-14 to 3-15). In summary, old (Barrigada) and young (Mariana) limestones comprise the bedrock at Finegayan and AAFB (Figures 4.1.1-1 and 4.3.1-1, respectively, of this SEIS). Based on available topographic and field data, there are 34 features that have been preliminarily identified as sinkholes/depressions that may contain sinkholes in the project area (Finegayan has 28 features and AAFB has 6 features identified). The soils are Guam Urban Land Complex and Guam Cobbly Clay Loam at Finegayan and Urban Land Complex at AAFB; none of the soils in the proposed Finegayan and AAFB project areas are identified as prime farmland by the USDA (Figures 4.1.1-2 and 4.3.1-2, respectively) (Young 1988). With respect to geologic hazards, conditions under Alternative E are similar to those described for Alternative A in Section 4.1.1.1; three minor faults are mapped within the Finegayan footprint and none are mapped within the AAFB footprint (see Figures 4.1.1-1 and 4.3.1-1, respectively).

In addition, the geological and soils affected environment for projects common to all alternatives (i.e., school expansions and off-site utilities) would be similar or identical to those described for Alternative A. The proposed reduction in the number of relocating Marines and dependents under the 2012 Roadmap Adjustments does not alter the description of the affected environment for geological and soil resources, but it would reduce some potential impacts to geological and soil resources that were determined to be less than significant or mitigated to less than significant in the 2010 Final EIS, which is described in the analysis of environmental consequences for Alternative E below.

#### 4.5.1.2 Environmental Consequences

Potential geology and soil impacts addressed in this section are limited to elements of the proposed action that could affect onshore landforms or that could be affected by geologic hazards. Potential soil contamination issues are addressed in Section 4.5.16.2 of this SEIS (Hazardous Materials and Waste).

**Construction**

Construction of the new cantonment/family housing, associated support facilities, and roads under Alternative E would include the same activities as described for Alternative A. Grading for construction of the cantonment/family housing areas and associated infrastructure (comprising the Finegayan and AAFB components) would include 3,732,871 yd³ (2,853,984 m³) of cut (excavation) and 2,958,469 yd³ (2,261,911 m³) of fill, resulting in a net of 774,402 yd³ (92,072 m³) of cut material available for use as needed.
While Alternative E would involve the largest volume of excavation of any of the five action alternatives (Alternative C would involve the least), it still does not include any substantial grade changes such as steep hills or canyons that would be leveled or filled. Similar to Alternatives A and C, only relatively minor changes in grade are anticipated to provide a buildable surface for construction of buildings, parking lots, and roadways associated with Alternative E. Because construction for Alternative E does not involve major elevation changes and would not substantially alter the surrounding landscape, affect important geologic features, or diminish slope stability, there would be less than significant direct, long-term impacts to topography and slope stability.

Under Alternative E, the same construction activities would take place as for Alternatives A and C, in similar geologic, soil, and seismic conditions. The soil types that would be disturbed would not be prime farmland as identified by the USDA. The same BMPs described for Alternative A would be implemented for Alternative E. Therefore, under Alternative E, the construction impacts would be similar to Alternative A and Alternative C; there would be less than significant direct, short-term impacts to soils from erosion and no direct or indirect impact to agricultural soils. Given compliance with 22 GAR Chapter 10 § 10106F, there would be no adverse impacts to sinkholes and direct short-term impacts to sinkholes would be less than significant. In addition, direct and indirect short-term impacts associated with geologic hazards would be less than significant.

Under Alternative E, the same residential, recreational, commercial, and administrative uses would take place in the Finegayan and AAFB project areas, as Alternative A and C, under similar geologic, soil, and seismic conditions. No prime farmland is identified within the Alternative E project footprint, so there would be no direct or indirect impact to agricultural soils as a result of Alternative E operations. The same erosion minimization measures, sinkhole BMPs and seismic design requirements described for Alternative A would apply to Alternative E. Therefore, with the operation phase of Alternative E, there would be no direct or indirect long-term impacts to topography and slope stability, and less than significant direct long-term impacts to soils from erosion. Given compliance with 22 GAR Chapter 10 § 10106F, there would be no adverse impacts to sinkholes. This would minimize potential geologic hazards associated with sinkholes and reduce potential direct long-term impacts to sinkholes to less than significant. Direct and indirect long-term impacts associated with geologic hazards would be less than significant.

Under Alternative E, operation of the utility and school expansions that are common to all alternatives would comprise the same activities, and would occur in the same geologic, soil, and seismic conditions as for Alternatives A and C. The same BMPs described for Alternative A would be implemented for Alternative E. Therefore, under Alternative E, the operational impacts of these components would be similar to Alternatives A and C and would be less than significant.
4.5.2 Water Resources

4.5.2.1 Affected Environment

Under Alternative E, the affected environment for water resources is as described for Alternative A and Alternative C (Sections 4.1.2 and 4.3.2, respectively). In addition, an extensive discussion of the affected environment for water resources on Guam is provided in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.1.2.2: Finegayan, page 4-26 and Section 4.1.2.1: Andersen AFB, pages 4-25 to 4-26).

Surface Water

There are no surface water resources in the Finegayan and AAFB project area or the utility corridor to AAFB. Existing impervious areas on the Finegayan project area amount to approximately 60 acres (24 ha), or about 6% of the proposed Finegayan impacted area of 945 acres (382 ha). Existing impervious areas on the AAFB project area amount to approximately 357 acres (145 ha), or 85% of the proposed AAFB impacted area of 420 acres (170 ha).

Groundwater

The Finegayan project area overlies the Finegayan and Agafa-Gumas basins of the NGLA and the AAFB project area overlies the Andersen Basin of the NGLA. The circumstances concerning the groundwater model developed by the USGS, the current well production, and the existing GWA interceptor sewer system are the same as described under Alternative A in Section 4.1.2.1 of this SEIS.

Nearshore Waters

Nearshore waters at Finegayan include Haputo Beach and nearshore waters at AAFB include Tarague Beach and the Pati Point Marine Preserve; these waters are classified as having M-1 water quality, the use of which is primarily recreational. The Finegayan and AAFB project area would be served by the Northern District WWTP, which discharges into the Philippine Sea near Tanguisson Beach (see description under Alternative A in Section 4.1.2.1 of this SEIS).

Wetlands

As indicated in the 2010 Final EIS, no wetlands were identified at the Finegayan or AAFB project areas.

4.5.2.2 Environmental Consequences

Construction

General construction impacts to water resources would be similar to those described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.1: North, pages 4-84 to 4-88) and under Alternative A in Section 4.1.2.2 of this SEIS. Construction impacts associated with the proposed approximately 11 new wells at AAFB, school expansions, and off-site utilities common to all cantonment/family housing alternatives would be the same as described under Alternative A in Section 4.1.2.2 of this SEIS. There would be no impacts to surface water, nearshore waters, and wetlands and less than significant short-term direct impacts to groundwater for these common elements.

In addition, there would be construction activities associated with the proposed Alternative E and the utility corridor to AAFB under Alternative E. Similar to Alternative A, Alternative E would occur in an area that does not contain waters of the U.S. but would comply with the Construction General Permit as described under Alternative A.
Construction under Alternative E would result in the potential for short-term increases in stormwater runoff and erosion. However, through compliance with the Construction General Permit and Program SWPPP and implementation of a site-specific SWPPP and associated erosion control, runoff reduction, and sediment removal BMPs (see Table 4.1.2-2), these effects would be minimized and off-site transport of stormwater runoff would be unlikely except during extreme weather events (i.e., typhoons). Specifically, the site-specific SWPPP would identify appropriate BMPs for the site that would serve to contain runoff and sediment on-site by reducing the flow rate of runoff and thereby minimize transport of suspended sediment through settling and promote infiltration of runoff.

**Surface Water**

No buildings/structures would be constructed in the 100-year or 500-year flood zones and no surface waters are located within or near the proposed construction areas under Alternative E. Given compliance with the Construction General Permit and implementation of a Program SWPPP and site-specific SWPPP, off-site transport of stormwater runoff, sediment, or other pollutants would be unlikely. Therefore, construction activities associated with Alternative E would result in no impacts to surface waters.

**Groundwater**

Construction activities under Alternative E would include stormwater runoff protection measures that would also serve to protect groundwater quality. By adhering to the provisions of the Construction General Permit and implementing BMPs associated with addressing site- and activity-specific water resource protection requirements, there would be a reduction in stormwater pollutant loading potential and thus a reduction in pollution loading potential to the underlying groundwater sub-basins of the NGLA. As described under Alternative A, an environmental and hydrogeologic assessment for the selected alternative would be performed for sinkholes within the project development footprint to ensure adverse effects to groundwater resources would not occur. Impacts associated with the induced civilian growth and construction/DoD workforce demand on potable water and the construction of the proposed approximately 11 new wells at AAFB would be the same as described under Alternative A in Section 4.1.2.2 of this SEIS.

Potential increases in the rate of sewage spills associated with the induced civilian growth and construction/DoD workforce would result in significant indirect impacts to groundwater quality as described under Alternative A in Section 4.1.2.2 of this SEIS. Mitigation for these impacts would be the same as described in Section 4.1.2.2 for Alternative A.

Given stormwater runoff protection measures (i.e., compliance with Construction General Permit requirements and implementation of BMPs), the environmental and hydrogeologic assessment for sinkhole protection (if encroachment is unavoidable), siting and construction of wells in accordance with GEPA regulations, minimal increase in water demand or withdrawal from the NGLA during the construction phase, and DoD assistance in identifying funding to upgrade sewer lines, construction activities associated with Alternative E at Finegayan and AAFB would result in less than significant short-term direct impacts to groundwater.

**Nearshore Waters**

General construction impacts to nearshore waters would be similar to those described under Alternative A in Section 4.1.2.2 of this SEIS. The Finegayan cantonment project area would be located between 0.5 and 1 mile (0.8 and 1.6 km) from nearshore waters, and the AAFB family housing project area would be located 0.5 mile (0.8 km) from nearshore waters. Given compliance with the Construction General Permit
and implementation of a Program SWPPP and site-specific SWPPP, off-site transport of stormwater runoff, sediment, or other pollutants would be unlikely (see discussion of BMPs under Construction). In addition, vegetative cover between the construction area and the edge of the steep cliffline and the shoreline would provide an additional buffer and protection from stormwater runoff or sediment reaching nearshore waters. Given adherence to the provisions of the Construction General Permit and implementation of BMPs, it is expected that stormwater runoff, sediment, or other pollutants would not discharge to nearshore waters.

Induced civilian and construction/DoD workforce growth during construction of the cantonment/family housing facilities under Alternative E would increase demand for wastewater treatment at the Northern District WWTP and disposal of generated wastewater. Due to the reduced population projection and related smaller increase in demand under the 2012 Roadmap Adjustments, this increase in wastewater discharge from the Northern District WWTP would be less than under the No-Action Alternative. However, as discussed in Section 4.1.14, Utilities in this SEIS, upgrades to the Northern District WWTP are already needed for the plant to achieve compliance with the current NPDES permit. Increasing the wastewater discharge from a non-compliant treatment plant could result in significant indirect impacts to nearshore waters during the period of non-compliance. The impacts to nearshore waters resulting from implementation of Alternative E would be considered significant and would be similar to significant impacts described for the other four cantonment/family housing alternatives. Mitigation for these impacts would be the same as described in Section 4.1.2.2 for Alternative A.

Therefore, with the mitigation to upgrade the Northern District WWTP treatment systems, the impact to nearshore waters could be beneficial in the long-term because the total volume of wastewater discharge from the Northern District WWTP would receive a higher level of treatment. However, until the WWTP upgrades are completed there would be an indirect and unmitigable significant impact to nearshore waters during construction.

**Wetlands**

No wetlands are located in or near the construction areas associated with Alternative E. Therefore, construction activities associated with Alternative E would result in no impacts to wetlands.

**Operation**

Alternative E would incorporate a LID approach in the final planning, design, and construction of the stormwater management system as described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.1: North, pages 4-85 to 4-87) and under Alternative A in Section 4.1.2.2 of this SEIS. Operation impacts associated with the proposed approximately 11 new wells at AAFB, school expansions, and off-site utilities common to all cantonment/family housing alternatives would be the same as described under Alternative A in Section 4.1.2.2 of this SEIS. There would be no impacts to surface water, nearshore waters, and wetlands and less than significant direct and indirect long-term impacts to groundwater for these common elements.

The proposed stormwater management system infrastructure improvements included as part of the proposed action would incorporate LID measures and BMPs for compliance with local and federal requirements that are designed to minimize potential impacts to downstream development, sensitive water resources, and ecology, as described under Alternative A in Section 4.1.2.2 of this SEIS. Alternative E would also be implemented in accordance with all applicable orders, laws, and regulations including the preparation and implementation of a SWPPP, SWMP, and SPCC plan that would control runoff and minimize potential leaks and spills.
Under Alternative E, the total impervious area on the Finegayan cantonment project area would increase by approximately 280 acres (113 ha) or 24% due to new facilities, and the total impervious area on AAFB housing would decrease by approximately 40 acres (16 ha) or 10%. The increase in impervious area for the Finegayan cantonment project area would result in an associated increase in stormwater runoff volume for each of the design storm events. Alternative E would result in increased stormwater runoff of 232 acre-feet (286,000 m$^3$) from the 25-year design storm and 338 acre-feet (471,000 m$^3$) from the 100-year design storm at Finegayan. At AAFB, stormwater runoff would decrease by 109 acre-feet (135,000 m$^3$) from the 25-year design storm and 158 acre-feet (195,000 m$^3$) from the 100-year design storm. The project design would include vegetated swales for conveyance and treatment and detention/retention ponds capable of capturing, storing, and treating additional runoff from the 25-year design storm (see Appendix F for examples of LID applications that would be used and conceptual design of stormwater runoff routing and pond locations). As part of the initial design, the project area was delineated into sub-basins with stormwater conveyance systems to route discharges to appropriately sized detention basins. For each sub-basin, water quality treatment strategies were selected based on the effectiveness of BMPs to treat identified pollutants of concern from proposed land uses within that sub-basin. The selected water quality treatment strategies would achieve reductions of non-point source pollutants to meet the same water quality requirements as identified under Alternative A in Section 4.1.2.2 of this SEIS. In addition, DON would develop and implement a “LID BMP O&M Inspection Checklist” consistent with the 2006 CNMI Guam Stormwater Management Manual to monitor and ensure the effectiveness of LID features during operation. Any deficiencies would be reported to and addressed by the future Public Works Department of the Marine Corps Base Guam.

The final Grading/Drainage/LID Study, dated July 2013, would be provided to the design team for guidance and implementation during design and construction. The designs performed by these contractors would be subject to review by DoD professionals and technical consultants to ensure proper implementation both during design and verification during construction.

**Surface Water**

No surface waters are located in or near the Alternative E project area and the implementation of an appropriate and comprehensive stormwater management plan utilizing a LID approach would ensure that there would be no increase in off-site transport of excess stormwater runoff, sediment, or other pollutants for up to the 25-year design storm event. Therefore, Alternative E would result in no impacts to surface waters.

**Groundwater**

Under Alternative E, proposed operations would be in compliance with the stormwater runoff protection measures identified above that would also serve to protect groundwater quality and recharge. Specifically, implementation of LID measures and the provisions of the SWPPP and associated erosion control activities would ensure that the stormwater runoff flowing into infiltration basins and recharging the aquifer would be of acceptable quality.

Compared to Alternative A, there would be less removal of secondary limestone forest (i.e., approximately 854 acres [346 ha] for Alternative E vs. 1,000 acres [400 ha] for Alternative A) and less area would be converted to impervious area (i.e., approximately 240 acres [97 ha] for Alternative E vs. 273 acres [110 ha] for Alternative A). Similar to Alternative A, these changes in land cover and impervious area under Alternative E would also result in minor changes to groundwater recharge rates. However, these types of changes in land cover and impervious area were accounted for during the development of a conceptual level of design for grading, drainage, and LID measures, and projected
changes in recharge rates would be managed through updating the USGS numerical groundwater model to determine modifications to groundwater pumping, as described under Alternative A. Increased groundwater withdrawal would also be the same as described under Alternative A in Section 4.1.2.2 of this SEIS. There would be short-term, localized significant impacts to the affected basin within the NGLA but less than significant impacts to the overall NGLA. There would be significant but mitigable impacts to groundwater quality from the increased flow through the deteriorating GWA interceptor sewer system. Potential mitigations would be the same as described for Alternative A in Section 4.1.2.2 of this SEIS.

Given stormwater runoff protection measures (i.e., implementation of LID and pollution prevention plans); implementation of water conservation measures; groundwater demand from the NGLA that would be substantially less than the sustainable yield; improved management of the NGLA through use of the numerical groundwater model; DoD assistance in identifying funding through the EAC process for an updated and expanded monitoring network; and other potential mitigation measures discussed above, operations associated with Alternative E would result in less than significant impacts to the overall NGLA; short-term, localized significant but mitigable impacts from groundwater extraction to the affected basin within the NGLA; and significant but mitigable impacts to groundwater quality from the increased flow through the deteriorating GWA interceptor sewer system.

Nearshore Waters

Under Alternative E, proposed operations would be in compliance with the stormwater protection measures identified above that would ensure that there would be no increase in off-site transport of stormwater runoff, sediment, or other pollutants to nearshore waters for up to the 25-year design storm event. In addition, the vegetative cover between the Finegayan cantonment to the cliff edge and Haputo Bay and the AAFB family housing to the cliff edge under Alternative E (approximately 0.5 mile [0.8 km]) would provide a substantially greater additional buffer and protection from stormwater runoff or sediment reaching Haputo Bay than under Alternative A, which would have a buffer of only approximately 36 feet (11 m) between the construction area and the edge of the steep cliff. Therefore, there would be no direct and indirect long-term impacts to nearshore waters from stormwater runoff associated with increased impervious areas under Alternative E.

Water resources would be impacted by the increased wastewater discharge from the Northern District WWTP for treatment and disposal of generated wastewater for the operation of Finegayan cantonment and AAFB family housing. The associated potential impacts and mitigation would be similar to those described for construction-related impact. Refer to construction impacts above for a detailed discussion of WWTP discharge impacts and mitigation.

Wetlands

No wetlands are located in or near the proposed operational areas under Alternative E. Therefore, operations associated with Alternative E would result in no impacts to wetlands.
4.5.3 Air Quality

4.5.3.1 Affected Environment

Under Alternative E, the affected environment for Air Quality is as described for Alternative A (Section 4.1.3.1) and Alternative C (Section 4.3.3.1).

The area covered by Alternative E at Finegayan and AAFB is in attainment for all criteria pollutants. Air quality conditions at Finegayan and AAFB are affected predominantly by on-road mobile sources, on-base stationary sources, and aircraft operations.

4.5.3.2 Environmental Consequences

Construction

Direct emissions for criteria pollutants and CO\(_2\) from short-term operation of on-site equipment and vehicles during construction (2016 through 2022) were estimated based on the acreage of disturbed earth and the number and type of facilities to be constructed. Given limited preparation activities anticipated in 2016, construction emissions are considered negligible and were not quantified for that year. The short-term direct emissions would be well below the potential impact significance criterion of 250 tpy for criteria pollutants, as shown in Table 4.5.3-1. The CO\(_2\) emissions during construction period would be less than those analyzed in the 2010 Final EIS resulting in less GHG impacts as compared to the No-Action Alternative.

Table 4.5.3-1. Finegayan Cantonment/AAFB Family Housing Annual Construction Emissions (2016-2022)

Legend: SO\(_2\) = sulfur dioxide; CO = carbon monoxide; PM\(_{10}\) = particulate matter (<10 microns); PM\(_{2.5}\) = particulate matter (<2.5 microns); NO\(_x\) = nitrogen oxides; VOC = volatile organic compounds; CO\(_2\) = carbon dioxide; neg = negligible.

Under Alternative E, the maximum emissions year on-site for annual PM levels predicted are slightly less than under Alternative A (Table 4.1.3-2) (i.e., 2.5 tpy as compared to 2.8 tpy for PM\(_{10}\) under Alternative A). Therefore, the short-term on-site hot-spot PM impacts around construction sites would be anticipated as less or similar to those under Alternative A that are shown in Table 4.1.3-3.

Off-Site On-Road Vehicle Hot-Spot Analysis for CO

The same hot-spot CO analysis procedures described for Alternative A were implemented in selecting the most congested and most affected intersections under this alternative for a hot spot impact analysis. Out of the 63 intersections, three worst-case intersections among those failing the screening were chosen for detailed analysis due to poor levels of service, high volumes, close proximity to sensitive receptors, and geographical representation. These three selected intersections are listed in Table 4.5.3-2.

CO concentration levels were predicted using CAL3QHC in association with the emissions factors predicted by MOVES. These predicted concentration levels were then added to the background levels to determine the total hot-spot concentration levels for construction and operation years. Table 4.5.3-2
shows the total concentrations for CO in comparison to the respective NAAQS. The predicted levels are well below the NAAQS, resulting in less than significant direct short-term CO impacts.

**Off-Site On-Road Vehicle Hot-Spot Analysis for PM**

As explained in Section 3.3.3, Alternative A is anticipated to have the greatest truck emissions impacts along the truck routes. Off-site on-road vehicle PM hot-spot impact concentrations for Alternative E would be similar in magnitude to those predicted for Alternative A (Section 4.1.3.2) at the analyzed intersections according to similar traffic patterns. Table 4.1.3-3 shows concentrations for PM ($\text{PM}_{10}$ and $\text{PM}_{2.5}$) during the construction period in comparison to their respective NAAQS. The predicted levels of PM are well below the NAAQS resulting in less than significant hot-spot PM impacts during the construction period.

**Off-Site On-Road Vehicle Hot-Spot Analysis for MSATs**

MSATs concentration levels were predicted using CAL3QHC in association with the emissions factors predicted by MOVES. The screening-level MSAT dispersion modeling analysis was conducted at sensitive (actual) and sidewalk receptors for 2021 and 2030, which represent the peak construction year and the design year, respectively. The analysis was conducted for both a 30-year exposure and a longer, more conservative exposure duration of 70 years for cancer risks.

Maximum estimated increases in cancer risk at any of the receptors due to the project, as shown in Table 4.5.3-3, are all less than the threshold criterion of 10 in a million. Therefore, the direct, short-term impacts of all carcinogenic MSATs are considered acceptable and would be less than significant.

Note: Target threshold is 10 excess cancer cases in a million.
Source: GDPW 2013.
The maximum chronic hazard index at any of the receptors due to project emissions are well below the target limit of 1, as shown in Table 4.5.3-4. Therefore, the direct, short-term impacts of all non-carcinogenic MSATs are considered acceptable and would be less than significant.

Source: GDPW 2013.

**Operation**

The traffic congestion conditions under Alternative E would be comparable to those discussed in Alternatives A and C. Under the Alternative E, the hot-spot impact analyses of off-site on-road vehicle CO and MSATs emissions during operational years were conducted and the analysis results are summarized in Table 4.5.3-2 for CO, and Tables 4.5.3-3 and 4.5.3-4 for carcinogenic and non-carcinogenic MSATs, respectively. Given the low levels of CO and MSATs impact concentrations predicted at hot spots under Alternative E, air quality impacts during long-term operational years are considered less than significant.

**4.5.4 Noise**

**4.5.4.1 Affected Environment**

The quantified noise impacts around AAFB from the 2013 AAFB AICUZ Study are used as the baseline noise levels for Alternative E. Figure 4.1.4-1 (see Section 4.1.4) shows the noise contours for the 65, 70, 75, 80, and 85 dB DNL contours and Table 4.1.4-1 (see Section 4.1.4) lists the corresponding amount of affected acreage.

In the vicinity of AAFB, noise contours extend off-base to the south and west, and there are populated areas currently within the noise contours up to 70 dB DNL as described in the 2013 AAFB AICUZ Study (Pacific Air Force 2013). Along the AAFB boundary, noise levels range from approximately 65 to 75 dB DNL in line with the end of the runway and dropping back down to below 65 dB DNL near both on- and off-base housing east of the Route 15 family housing gate.

**4.5.4.2 Environmental Consequences**

**Construction**

Under this alternative, noise would be generated from construction of various facilities, roadways, and infrastructure for development of the cantonment area, as well as noise from construction of off-site utilities development and DoD school expansions at AAFB. Marine Corps family housing under this alternative would be located at the area currently occupied by existing Air Force family housing.

Noise generated by construction activities for the main cantonment portion of this alternative would be similar to construction noise for Alternative A. For noise modeling purposes, it is assumed that 10 pieces of heavy equipment including multiple graders, excavators, dump trucks, and pavers would be used simultaneously at points nearest to the closest receptors for construction of the cantonment area.
Receptors that might be affected by Alternative E construction noise would comprise approximately 20 houses along Route 3 across the road from the proposed cantonment location. According to the Guam Bureau of Statistics, the average household size in the area is 3.67 people per household (GBSP 2010), thus it is estimated that about 70-75 people in these 20 houses that could be affected by implementation of Alternative E. Short- and long-term construction noise from development of the cantonment area would be the same as described for Alternative A in Section 2.4.4.1. The closest proposed construction activity for this alternative would occur approximately 500 feet (152 m) from the average receptor, with Route 3 frontage and noise levels estimated to be 65.4 dBA L_{eq}. Short-term increases in truck traffic used to transport materials on- and off-site would also produce noise disturbance of approximately 65 to 70 dBA L_{eq} within and near the construction corridors. Minimal to negligible direct impacts from construction noise are expected to result. In addition, direct short-term noise impacts would be less than significant because none of the houses along Route 3 would be close enough to experience noise exposure exceeding 75 dBA per USEPA guidelines (USEPA 1974). Long-term construction noise impacts would result from noise generated throughout the entire duration of construction. Construction activities would need to be within 525 feet (160 m) of the receptor to generate noise levels above the 65 dBA FICUN threshold. The impacted area at this distance comprises a very small percentage (<1%) of the total construction area, and would be considered short-term noise exposure because it would not remain at a consistent level for the entire 10-year period. Therefore, from this perspective, direct, long-term noise impacts from construction within the 525 feet zone (160 m) would be less than significant. Long-term construction noise impacts can also be addressed by modeling noise levels at the center of the cantonment area. The distance to the edge of the boundary is 2,500 feet (762 m), and if the amount of noise-generating construction equipment doubled in number, noise levels would be 54.5 dBA. This level is well below the FICUN level and meets the USEPA goal for an outdoor noise level of 55 dBA. Long-term direct and indirect noise impacts would be less than significant.

Housing construction noise would be similar to Alternative C and the existing (as well as proposed) housing abuts the property line and civilian housing south of the boundary abuts the property line from the south side. As a result, the proposed construction would be within 150 feet (46 m) of residences adjacent to AAFB housing. For this alternative, a construction scenario involving five pieces of heavy equipment operating at 150 feet (46 m) and five operating at 200 feet (61 m) is used since ten pieces of heavy equipment physically cannot operate at the same location 500 feet (46 m) at the same time relative to a receptor. Under this scenario, noise levels would be at 74.8 dBA L_{eq}, above the USEPA threshold guideline of 70 dBA L_{eq}. The 70 dBA L_{eq} threshold is used in this case because the construction would occur in areas with an ambient noise level greater than 60 dBA DNL. Although this represents the maximum potential adverse effect, it would be physically difficult to operate this many pieces of heavy equipment in such tight proximity to each other. As described for the other alternatives, the construction schedule for Alternative E implementation would be spread out. Approximately 20 homes housing about 75 people would be affected by noise from the family housing construction. Under this alternative, the following two different locations are analyzed: from a residential perspective and from the center of the family housing area. From the perspective of an individual receptor along the southern boundary of AAFB, noise levels above 65 dB would be considered incompatible for long-term land use noise exposure. The center of the family housing would be approximately 1,700 feet (518 m) from the southern boundary of AAFB and long-term noise levels would be about 58 dBA and well less than the FICUN criteria. Consequently, short-term and long-term construction noise impacts would be less than significant for Alternative E.
Construction activities common to all alternatives include off-site utilities and school expansions. Impacts due to these common construction projects would be as described in Section 4.1.4.2.

Consequently, potential direct and indirect short-term noise impacts under Alternative E for construction activities at Finegayan and construction activities for facilities common to all alternatives would be less than significant because increased noise levels would be short-term and would be below USEPA guidelines of 75 dBA $L_{eq}$.

**Operation**

Similar to Alternatives A and C, long-term noise impacts due to operation of the cantonment and family housing areas at AAFB would be considered less than significant.

After all construction has been completed, the long-term noise generating activities at Finegayan would be primarily due to traffic and aircraft noise. Traffic noise along Route 3 would increase but would be less than the levels described in the 2010 Final EIS (Volume 6, Chapter 8: Noise, Section 8.2.6: Off-Base Roadways, pages 8-14 to 8-15 and Volume 9, Appendix G: Chapter 6: Noise, Guam Community Build-up Figures, pages 1 to 10). Traffic noise under this alternative was estimated by comparing the increase of traffic relative to baseline for the 2010 Final EIS qualitatively and the increase of traffic due to this alternative. Using these comparisons and knowing the modeled noise levels from the 2010 Final EIS, the long-term, operational noise levels for implementation of Alternative E can be inferred. The highest noise levels along Route 3 determined in the 2010 Final EIS were 66 dBA at the nearest residences on Route 3 south of Route 28 to the intersection of Route 1. Traffic levels along that stretch of Route 3 and portions of Route 1 would be LOS “F,” and compared to traffic along the same area under this alternative, the LOS would also be “F,” indicating the road is beyond full capacity. Although the overall population increase would be less than predicted under the 2010 Final EIS, traffic noise would not appreciably change from the 2010 Final EIS because the road would be at full capacity (FHWA 2013). There would be no appreciable change in noise levels because an LOS of “F” is stop-and-go traffic indicative of heavy traffic. The noise levels would not change, just the duration of the levels. There would be less of an increase of population; therefore, the time of stop-and-go traffic would be less than the full buildup described in the 2010 Final EIS. However, GDPW transportation noise standards of 67 dBA would not be exceeded. There would be no new flying or range operations (and associated noise generation) at Finegayan, and long-term operation of Alternative E would not include industrial-type activities. Noise would be similar to an office park setting.

Aircraft noise generated by aircraft operating at AAFB would continue to affect family housing on AAFB. The proposed housing areas on AAFB would be located just outside the 65 dBA DNL noise zones with approximately the same amount of area in each zone. Details regarding compatibility are provided in Section 4.3.6, Land and Submerged Land Use of this SEIS.

Noise mitigation improvement such as sound walls would be constructed under the 2010 Final EIS reducing noise impacts in areas that are reasonable and technically feasible. Consequently, direct, long-term noise impacts under Alternative C would be less than significant.

Consequently, direct and indirect long-term noise impacts at Finegayan would be less than significant.
4.5.5 Airspace

4.5.5.1 Affected Environment

Airspace that would be impacted by the proposed action would be the same as described in the 2010 Final EIS. As indicated in Section 3.1.5 of this SEIS, designated airspace is associated with Guam International Airport and AAFB. Characteristics of the airspace have not changed since the 2010 Final EIS. Operations and functions associated with the cantonment/family housing facilities would consist of support, maintenance/storage, housing, and non-live fire training functions (see Section 2.2.1). No construction or operation activities would require changes to airspace. Therefore, the affected environment for airspace is only discussed in the context of the LFTRC components of the proposed action as provided in Chapter 5 of this SEIS.

4.5.5.2 Environmental Consequences

As discussed above, there would be no construction or operation activities requiring changes to airspace. Therefore, there would be no direct or indirect short- or long-term impacts on airspace from this component of the proposed action.

4.5.6 Land and Submerged Land Use

4.5.6.1 Affected Environment

The affected environment for land use associated with Alternative E is as described for Alternatives A (Section 4.1.6.1) and C (Section 4.3.6.3). In summary, the land and submerged lands associated with Finegayan cantonment, including Potts Junction, and AAFB family housing are federally owned. Finegayan is used primarily for communications functions, but there are community support and existing rifle and pistol small arms ranges. The SDZ for the ranges does extend into submerged lands and public access is restricted during training events for safety reasons. The AAFB has a full complement of land uses associated with an operational airbase and the family housing area is located on the southeastern boundary of the base. The Air Force operational facilities are focused around the airfield that is centrally located within the Main Base. Air Force housing and community support are located in the southeast portion of the Main Base. There are land use constraints that affect the Main Base, ESQD arcs associated with the MSA, the APZs and noise contours associated with the Main Base airfield, and the training range SDZs, as shown on Figure 4.5.6-1.

Adjacent land uses to the Finegayan parcel are private land (planned land use park/open space) and AAFB to the north, Route 3 and residential to the east, vacant open space (planned land use Hotel and Resort) to the south and the Philippine Sea to the west. The planned land uses are as described for Alternative A and shown on Figure 4.5.6-1.

The adjacent land use to the AAFB family housing area is residential and planned for residential.

4.5.6.2 Environmental Consequences

Land use impacts are addressed in this section. Land ownership impacts are addressed in Section 4.5.15, Socioeconomics and General Services.

Construction

As previously discussed in Section 3.6.3.1, Methodology, all changes in land use are considered long-term operational impacts. Therefore, there is no construction-phase analysis for this resource under any of the alternatives assessed in this SEIS.
Figure 4.5.6-1
Land Use in the Vicinity of Finegayan Cantonment/AAFB Housing Alternative E

Sources: DON 2010, NAVFAC Pacific 2013
Operation

Alternative E would be generally restricted to Finegayan and AAFB (see Figure 4.5.6-1); however, there are off-base improvements (utilities and education facilities), some of which are specific to this alternative and some of which are common to all cantonment/family housing alternatives. Similar to Alternative A, Alternative E would require expansion of DoDEA High School and the Andersen Middle School. The schools are located on federal land and would be compatible with adjacent community support facilities on the installation and residential land uses in the surrounding communities. There would be no land use impacts on the surrounding communities.

All cantonment alternatives require water well development on AAFB. The affected environment and environmental consequences are described in Section 4.3.6 of this SEIS. The off-base utility improvements specific to this alternative (see Figure 2.4-13 in Chapter 2 of this SEIS) would be placed underground along existing roadways or within existing utility easements along Routes 3, 3A and 9. The off-base utility improvements common to all cantonment/family housing alternatives utility improvements would also be aligned along existing roadways (Routes 1, 3, and 9) (see Figure 2.4-14 in Chapter 2 of this SEIS). There would be no impact on land use resulting from the off-base utility improvements. However, additional inter-base IT/COMM connectivity would be required as described in Chapter 2. This includes the connection between AAFB and the existing Tata Cable landing facility in southern Guam, which would require new rights-of-way along some southern roads and the access road to the Tata facility.

The land use impacts associated with the Alternative E Finegayan cantonment are as described for the cantonment of Alternative A (Section 4.1.6.2). In summary, there would be no impact to the existing communications mission at Finegayan. Open space is incorporated in the design, but there would be less open space than currently exists at the parcel, resulting in less than significant direct impacts on land use in the adjacent civilian community. The proposed land uses on the Finegayan and Potts Junction parcels would be compatible with existing and planned Residential and Village Center adjacent land uses (Figure 4.5.6-1).

The land use impacts associated with the AAFB family housing are as described for Alternative C family housing (Section 4.3.6.2). The AAFB family housing would require redevelopment and expansion of existing military housing in the southeastern portion of Main Base adjacent to the installation boundary. There would be a long-term increase in development density in the housing area. The maximum height of the cantonment buildings would be six stories and the housing would be a maximum of two stories. Open space is incorporated in the design, but there would be less open space than currently exists at the parcel resulting in less than significant direct impacts on land use in the adjacent civilian community. The proposed family housing and community support facilities are consistent with existing land use planning for AAFB. However, as stated in the Noise Section, 4.3.4.2, aircraft noise generated by aircraft operating at AAFB would continue to affect family housing on AAFB.

The DoD Guidance discourages housing in areas above 65 dBA DNL and strongly discourages development in 70 dBA or greater. When these constraints are unavoidable, houses may be allowed with the incorporation of noise level reduction design features. Noise level reduction of 25 dBA would be required for 65-69 dBA DNL and 30 dBA for 70-74 dBA DNL, no noise level reduction is required for 60-64 dBA DNL (DoD 2011). Figure 4.5.6-1 shows the 70 dBA DNL noise contour generated by the AAFB airfield encumbering a portion of the family housing units. The long-term impact of the existing noise levels at AAFB on the proposed housing would be less than significant.
The proposed family housing at AAFB would be consistent and compatible with adjacent off-base existing and planned residential land use to the south. There would be no new access restrictions imposed on the public under this alternative and no impact on access was identified. Additionally, no submerged lands would be affected by implementation of Alternative E.

Alternative E would have similar impacts as Alternative A and C and less of an impact on land use resources compared to Alternative B.

4.5.7  Recreational Resources

4.5.7.1  Affected Environment

Use of the recreational resources located at Finegayan and AAFB are subject to the same access requirements as other on-base facilities; therefore, only installation personnel and guests are able to use the land-based recreational resources at Finegayan. Offshore and recreational uses in the area but outside the installation boundary are open to the public. One exception is the archery hunting area established within AAFB and north of Finegayan that is accessible to the public.

As described for Alternative A in Section 4.1.7.1, the recreational resources at Finegayan are located primarily along the coastal area of the property and centered on the Haputo ERA. Table 4.1.7-1 identifies the recreational resources near Finegayan. In summary, the recreational activities include hiking trails, fishing, swimming, snorkeling, and scuba diving.

As described for Alternative C in Section 4.3.7.1, the housing area would be constructed and/or replaced contiguous to Palm Tree Golf Course on the southeastern edge of the base. This golf course is not open to the public. AAFB existing recreational facilities include outdoor playing fields, a fitness center, a recreational center, an auditorium/theatre, and a youth center. Table 4.3.7.1 identifies other recreational activities within AAFB land or submerged land including, hiking, beaches, picnic areas, camping sites, parks, fishing, and scuba diving sites.

4.5.7.2  Environmental Consequences

Construction

The construction impacts would be as described for Alternatives A (Section 4.2.7.2) and C (Section 4.3.7.2). The short-term increase of construction-related vehicles on roads may cause delays to persons accessing recreational areas in both the Finegayan and AAFB areas. Staged construction equipment would not obstruct access to, or the use of, the recreational resources, but would inconvenience resource seekers (i.e., potential detours, longer waits, and other similar nuisances).

Similar to the other alternatives, a surge in construction-related population may lead to a reduction of recreational opportunities at existing facilities as more users would compete for recreational use (e.g., competing for picnic shelters). This competition for resources would likely be worse during weekends, holidays, and the months of July through March, which experience heavier tourist traffic. The general wear and tear of the available amenities would likely be accelerated due to the presence of additional users. However, the construction of Alternative E would not substantially reduce recreational opportunities, cause substantial conflicts between recreational users, or cause substantial deterioration of recreational resources. The road to Haputo and Double Reef trailheads would remain open during construction of the Finegayan cantonment. Therefore, Alternative E would result in short-term, less than significant direct impacts to recreational resources.
Operation

The operational impacts on recreational resources would be similar to those described under Alternative A (Section 4.1.7.2) and C (Section 4.3.7.2) because the same increases in on-island military population and pressure of recreational resources are proposed for all alternatives. The long-term addition of potential users could result in further congestion of recreation resources at AAFB and other sites on Guam.

The recreational resources at AAFB, including swimming at Tarague Beach and Sirena Beach, may be near carrying capacity. The construction of recreational facilities at AAFB would ensure that the addition of approximately 5,000 Marines and approximately 1,300 dependents to AAFB would not accelerate the deterioration of the existing recreational resources at AAFB and other sites on Guam. Therefore, direct and indirect long-term impacts to recreational resources would be less than significant.

The recreational resource impacts would be similar to Alternative A and C. Since Alternative E does not have significant impacts to recreational resources, the magnitude of recreational impacts would be less than Alternative D, which has potentially significant impacts. Relative to Alternative B that includes South Finegayan, the public would continue have access to the Latte Stone Park under Alternative E because the park is south of the Finegayan cantonment area.

4.5.8 Terrestrial Biological Resources

4.5.8.1 Affected Environment

The affected environment for the area associated with the proposed Finegayan cantonment component is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.3.2: Finegayan, pages 10-34 to 10-39), and is summarized in Section 4.1.8.1 of this SEIS. The affected environment for terrestrial biological resources associated with the proposed AAFB housing component is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.3.1: Andersen AFB, pages 10-16 to 10-31), and is summarized in Section 4.3.8.1 of this SEIS.

The description of the affected environment for each area is supplemented and updated with new information regarding biological surveys within the project areas conducted after the 2010 Final EIS. The proposed reduction in the number of relocating Marines and dependents under the 2012 Roadmap Adjustments does not alter the description of the affected environment for terrestrial biological resources, but it would reduce some potential impacts to terrestrial biological resources as described in the analysis of environmental consequences for Alternative E below. In addition, the biological resources affected environment described in this section includes areas associated with the development of infrastructure common to all alternatives (e.g., off-site utilities).

Vegetation Communities

Figures 4.5.8-1 and 4.5.8-2 show the vegetation communities within the Alternative E project footprints on Finegayan and AAFB. See Sections 4.1.8.1 and 4.3.8.1 for a description of the vegetation communities for Finegayan and AAFB, respectively. Utility corridors associated with Alternative E follow roadways, are in high-use areas on developed land, or are in areas with small amounts of herbaceous-scrub vegetation (Figure 4.5.8-2).

Terrestrial Conservation Areas

Overlay Refuge. Currently, 21,690 acres (8,778 ha) is Overlay Refuge on lands administered by the DoD on Guam. The Overlay Refuge encompasses lands identified in the initial recovery plans as essential habitat for the recovery of the Mariana fruit bat, Guam Micronesian kingfisher, Mariana crow, and Guam rail. However, only the Mariana fruit bat still occurs in the wild on Guam. Additional information on Overlay Refuge lands is provided in Section 3.8.1.2 of this SEIS and the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.1.3: Special-Status Species, pages 10-8 to 10-9). All of the undeveloped area of Finegayan is within the established Overlay Refuge (Figure 4.5.8-3).

The proposed Alternative E housing area on AAFB does not contain any terrestrial conservation areas (Figure 4.5.8-3).

Wildlife - Native Species

See Sections 4.1.8.1 and 4.3.8.1 for a discussion of wildlife for Finegayan and AAFB, respectively.

Special-Status Species: Federal ESA-Listed and Proposed Species

One federal ESA-listed species (Mariana fruit bat), two proposed endangered species (Dendrobium guamense and Tuberolabium guamense), and one proposed threatened species (Tabernaemontana rotensis) may occur within Finegayan and the proposed Alternative E utility corridor at AAFB (Figures 4.5.8-4 and 4.5.8-5; Table 4.5.8-1). Although “suitable habitat” for special-status species is present within the Alternative E project areas, the brown treesnake, the primary factor in the extirpation of special-status wildlife species on Guam and one of the largest obstacles to achieving recovery of special-status species, is still considered abundant and widespread on Guam. Until brown treesnares are suppressed or removed from at least targeted areas on Guam, the habitat is not in a suitable condition to support the survival of special-status species due to current snake abundance on Guam (e.g., Guam Micronesian kingfisher, Guam rail, Mariana crow) (USFWS 2010a). A brief summary of each species is provided in Sections 4.1.8.1 (Finegayan) and 4.3.8.1 (AAFB), including new information about each species within the project area since the completion of the 2010 Final EIS. Further detail is provided in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.3.1: Andersen AFB, pages 10-34 to 10-31).

Special-Status Species: Guam-Listed and SOGCN

Three Guam-listed endangered species (Micronesian starling, moth skink, and Pacific slender-toed gecko) occur within the Alternative E project areas on Finegayan and AAFB (see Figures 4.5.8-2, 4.5.8-4, and 4.5.8-5; Table 4.5.8-1). A brief summary of each species is provided in Sections 4.1.8.1 (Finegayan) and 4.3.8.1 (AAFB), including new information about each species within the project area since the completion of the 2010 Final EIS. Further detail is provided in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.3.1: AAFB, pages 10-34 to 10-31).

### 4.5.8.2 Environmental Consequences

**Construction**

**Vegetation.** The vegetation communities that would be impacted during proposed facility and infrastructure construction activities under Alternative E are shown within the outlined impact footprint in Figure 4.5.8-1 for the proposed Finegayan cantonment area and Figure 4.5.8-2 for the proposed AAFB housing and utility areas. Under Alternative E, approximately 2 acres (0.8 ha) of primary limestone forest and 778 acres (315 ha) of secondary limestone forest would be removed during proposed construction activities (Table 4.5.8-2). Approximately 132 acres (54 ha) of other plant communities, primarily herbaceous scrub, and 1,037 acres (420 ha) of developed areas would also be impacted.

Native limestone forest, both primary and secondary, has been significantly reduced on Guam due to past and ongoing actions including extensive disturbance during and after WWII, widespread planting of non-native species; and impacts from non-native ungulates; development; fire; and deforestation. As stated in Section 3.8.1.1, limestone forests provide important since they retain the functional ecological components of native forest that provide habitat for the majority of Guam’s native species, including ESA-listed, ESA-proposed, and Guam-listed species and Guam SOGCN, as well as maintaining water
quality and reducing fire risk. Non-native forest communities (e.g., tangantangan, Vitex) significantly alter the forest structure, composition, and resilience to other disturbance processes and do not provide the conditions suitable for native flora and fauna species to persist (Morton et al. 2000; GDAWR 2006; Guam Department of Agriculture 2010; JRM 2013).

Legend: PLF = primary limestone forest; SLF = secondary limestone forest; HS = herbaceous scrub; TT = tangantangan; CP = coconut plantation; Dev = developed.

Of the 18,538 acres (7,502 ha) of primary and secondary limestone forest found on Guam, approximately 13,110 acres (5,305 ha) (or 71%) are found on federal lands, primarily within AAFB, Finegayan and the NAVMAG (USFS 2006). Under Alternative E, a total of approximately 2 acres (1 ha) of primary limestone forest and 778 acres (315 ha) of secondary limestone forest would be removed, primarily associated with the cantonment housing component (see Table 4.5.8-2). Therefore, given the importance of limestone forest habitat for native species and the continuing loss of native limestone forest across Guam, the conversion of 780 acres (316 ha) of limestone forest to developed area would be a significant but mitigable impact to the regional vegetation community and its function.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct, long-term impacts of proposed construction activities on vegetation communities with implementation of Alternative E. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the contractor education program.
- **Onsite Vegetation Waste Management Procedures.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the vegetation waste management procedures.
- **DON Guam Landscaping Guidelines.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of landscaping guidelines.
• **Contractor Plans and Specifications.** All construction would occur within the limits of construction shown in the project figures.

**Potential Mitigation Measures**

To mitigate for significant impacts to limestone forest, the DON proposes to implement forest enhancement on a minimum of 780 acres (316 ha) of limestone forest. Forest enhancement would include but is not limited to the following actions:

- Ungulate management consisting of exclusion fencing and active control (i.e. trapping, snaring, shooting) with the goal of eradication within the fenced areas.
- Non-native, invasive vegetation removal.
- Propagation, planting, and establishment of native species that are characteristic of native limestone forest habitats (e.g., A. mariannensis, G. mariannae, F. prolixa, M. citrifolia, W. elliptica).

The degradation and loss of primary limestone and other forest habitats resulting from ungulate damage and invasion by alien plant species has substantially diminished the extent of habitat for native species in the Mariana archipelago. The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including special-status species. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

**Terrestrial Conservation Areas.** All cantonment components would be constructed on the upper plateau area of Finegayan. Construction personnel are issued base passes for official business only within proposed construction areas; these restrictions are specified in construction contracts. Use of Haputo ERA is not expected to increase as a result of construction activities under Alternative E, therefore there would be no impact associated with construction personnel. In addition, locating the proposed housing component of the proposed action at AAFB and not at Finegayan as is proposed under Alternatives A and B, would further reduce potential impacts on the Haputo ERA. The Haputo ERA would not be directly impacted and would continue to serve as a migration corridor for species moving or dispersing from AAFB and Finegayan to suitable habitat further south or from these areas to the north.

The only terrestrial conservation area within the impacted areas of Alternative E is Overlay Refuge (see Figure 4.5.8-3). Overlay Refuge lands were established for the purpose of conserving and protecting ESA-listed species and other native flora and fauna, maintaining native ecosystems, and conserving native biological diversity, recognizing that the primary purpose of lands within the Overlay Refuge is to support the national defense missions of the Navy and Air Force.

Under Alternative E, approximately 1,065 acres (431 ha) of Overlay Refuge lands (Table 4.5.8-3), or 4.9% of the total Overlay Refuge lands on Guam, would be directly impacted. This area overlaps with the vegetation communities discussed above. The majority of the impacted Overlay Refuge lands are associated with the cantonment component within Finegayan and is comprised primarily of secondary limestone forest (Table 4.5.8-3 and Figure 4.5.8-3). Therefore, because proposed construction activities would convert 1,065 acres (431 ha) of Overlay Refuge lands to developed areas, this would be a significant loss to the conservation function of these lands and implementation of Alternative E would result in significant but mitigable impacts to terrestrial conservation areas.

Legend: PLF = primary limestone forest; SLF = secondary limestone forest; HS = herbaceous scrub; TT = tangantangan; CF = Casuarina forest; CP = coconut plantation; Dev = developed.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct, long-term impacts of proposed construction activities on terrestrial conservation areas with implementation of Alternative E. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

Best Management Practices

The same BMPs discussed previously under Vegetation would be implemented for terrestrial conservation areas.

Potential Mitigation Measures

To mitigate for significant impacts to terrestrial conservation areas, the DON would submit a proposal to CNO Energy and Environmental Readiness Division to designate an ERA on the NAVMAG to conserve native limestone forest in southern Guam which provides habitat for special-status species. The DON has defined an ERA as a physical area or biological unit in which current natural conditions are maintained insofar as possible. These conditions are ordinarily achieved by allowing natural, physical, and biological processes to prevail without human intervention. However, under unusual circumstances, deliberate manipulation (e.g., removal or control of invasive species) may be utilized to maintain the unique feature that the ERA was established to protect (NAVFAC 1996). The proposed NAVMAG ERA would encompass approximately 553 acres (234 ha). Although the proposed NAVMAG ERA is currently part of the Overlay Refuge, implementation of these potential mitigation measures would provide an increased level of protection by further ensuring this area is maintained in natural and near natural conditions and to have available such areas for research and scientific manipulation (NAVFAC 1996; NAVFAC Marianas 2010).

In addition, the DON proposes to submit a proposal to CNO Energy and Environmental Readiness Division to expand the existing Orote ERA by approximately 32 acres (13 ha) of terrestrial habitat. The Final Orote ERA Expansion proposal was completed FY 2013 and will be submitted for approval in 2014.

Wildlife - Native Species. No additional impacts to native wildlife species from construction of the cantonment area at Finegayan beyond those described for Alternative A would occur under Alternative E. Impacts to native wildlife species for construction of the family housing components at AAFB would be as described for Alternative C. Implementation of Alternative E would not have a significant adverse effect on a population of any migratory bird species or other native wildlife species. Non-listed native
reptiles are abundant throughout Guam and impacts to vegetation communities under Alternative E would result in less than significant impacts to non-listed native reptile populations. Therefore, as presented above, long-term, direct impacts to populations of native wildlife species would not result because these species are abundant in surrounding areas and could repopulate portions of suitable habitat within the affected area after construction. Therefore, direct impacts to native wildlife would be less than significant with implementation of proposed construction activities associated with Alternative E.

Proposed construction activities and associated movement of materials onto and off of Guam could increase the potential for the spread of existing or introduction of new non-native invasive species. To prevent the inadvertent spread of non-native species on Guam or to other locations off of Guam, the DON would implement standard biosecurity measures (e.g., HACCP, brown treesnake interdiction measures, coconut rhinoceros beetle vegetation management procedures, outreach/education, and monitoring to evaluate effectiveness of HACCP) into construction protocols, procedures, and activities.

The following BMPs would be implemented to avoid and minimize potential direct, long-term impacts of proposed construction activities on native wildlife with implementation of Alternative E.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

With implementation of these BMPs, including development of HACCP plans and ongoing implementation of standard DON biosecurity protocols regarding detection and management of non-native species (e.g., coconut rhinoceros beetle), the potential for the introduction of new or spread of existing non-native species on Guam is substantially reduced. Therefore, there would be less than significant impacts to native wildlife species related to the potential introduction and establishment of non-native species with implementation of proposed construction activities associated with Alternative E.

Damage of forested areas, particularly primary and secondary limestone forests, by non-native ungulates (i.e., deer and pigs) is a serious concern on Guam. Under Alternative E, removal of large amounts of secondary limestone forest currently used by ungulates would displace and concentrate ungulates into adjacent areas, resulting in even higher densities and potentially greater habitat damage. Potential impacts from changes in ungulate densities from construction projects within the same or similar habitat areas as proposed in this SEIS were addressed in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.2.1: North, page 10-115).

The implementation of the potential mitigation measures under the Vegetation section above would also benefit native wildlife species. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures.
Special-Status Species: Federal ESA-Listed and Proposed Species

**MARIANA FRUIT BAT.** Approximately 719 acres (291 ha) of Mariana fruit bat recovery habitat would be removed due to proposed construction activities at Finegayan and AAFB under Alternative E (Table 4.5.8-4). This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

</tr>
</tbody>
</table>

Additional potential direct temporary impacts to the Mariana fruit bat from construction activities are based on the distances from those activities that are likely to cause disturbance to this species (e.g., noise, human activity, lighting). The evaluation of fruit bat disturbance is based on the approach used by USFWS in previous ESA section 7 formal consultations and associated BOs (e.g., USFWS 2006b, 2010). These distances are: roosting habitat within 492 feet (150 m) and foraging habitat within 328 feet (100 m) from the activity (Wiles, personal communication 2006 and Janeke, personal communication 2006, respectively, as cited in USFWS 2006b).

The Mariana fruit bat is currently limited to the few areas on Guam away from human activities and with suitable habitat, primarily on federal lands on NAVMAG and AAFB (JRM et al. 2012a, 2012b; JRM 2013; A. Brooke, NAVFAC Marianas, personal communication). There are no historical fruit bat roost sites at Finegayan and there have been only two observations of fruit bats on or adjacent to Finegayan since the 1990s (Wiles et al. 1995; Brooke 2008). However, there is recovery habitat within the Alternative E impacted areas. Although it appears that fruit bats are frequently observed at AAFB north of the proposed Alternative E impacted area (see Figure 4.5.8-5), the clusters of fruit bat detections are an artifact of the number of station count surveys conducted in that particular location. No more than two fruit bats have been observed in flight during each detection during recent surveys at AAFB (JRM et al. 2012b, 2012c, 2012d).

Illegal hunting, loss and degradation of native forest, predation by the brown treesnake, and the increased extirpation risk owing to the high vulnerability of very small populations continue to limit the potential recovery of the species on Guam (USFWS 2010; JRM 2013). Based on the equilibrium/carrying capacity of snakes on Guam (Rodda and Savidge 2007), implementation of the proposed action is not expected to increase the likelihood of predation by the brown treesnake on Mariana fruit bats.

Although the loss of 719 acres (291 ha) of fruit bat recovery habitat on Guam would not preclude the recovery or survival of the fruit bat, it would reduce the total number of bats that the island can support. Given this loss of recovery habitat and the critically low numbers of bats on Guam, there would be significant but mitigable impacts to the Mariana fruit bat.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct long-term impacts of proposed construction activities on Mariana fruit bats with
implementation of Alternative E. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2, *Construction, Vegetation* for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, *Construction, Vegetation* for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, *Construction, Vegetation* for a detailed description of the contractor education program.
- **Pre-Construction Surveys.** Surveys would be completed within suitable fruit bat habitat 1 week prior to onset of construction activities following the USFWS-approved JRM protocol. If a fruit bat is present within 492 feet (150 m) of the project site, the work must be postponed until the bat has left the area.
- **Lighting Installation.** Lighting would be designed to meet minimum safety and AT/FP requirements. Hooded lights would be used to the maximum extent practicable at all new roads and facilities adjacent to fruit bat habitat. Illumination of forest would be kept to an absolute minimum.

**Potential Mitigation Measures**

The same potential mitigation measures discussed previously under *Vegetation* (i.e., forest enhancement of 780 acres [316 ha] of limestone forest) would be applicable for the Mariana fruit bat and its recovery habitat. The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Mariana fruit bat. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

**MARIANA CROW.** The Mariana crow is extirpated and no longer present on Guam, due primarily to predation by the brown tree snake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the crow is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the crow, nor successful suppression of the brown tree snake to a level which would support re-introduction. Until the crow is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative E, impacts to the crow would be limited to recovery prospects. If crows are reintroduced and exposed to construction activities under Alternative E, they may be disturbed (DON 2014).

Although the crow no longer occurs on Guam, approximately 719 acres (291 ha) of crow recovery habitat would be removed due to proposed construction activities at Finegayen and AAFB under Alternative E (Table 4.5.8-5). This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

</tbody>
</table>

Although this loss of recovery habitat on Guam would not preclude the recovery of the crow should it be reintroduced to Guam in the future, it would reduce the total number of crows that the island can support. If and when the crow is reintroduced to Guam, the best available information indicates project-related noise would not further reduce the amount of recovery habitat suitable for this species’ breeding, feeding and sheltering (USFWS 2010). Given this loss of recovery habitat, there would be significant but mitigable impacts to the recovery of the Mariana crow.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct long-term impacts of proposed construction activities on the recovery of the Mariana crow with implementation of Alternative E. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

**Potential Mitigation Measures**

- **Brown Treesnake Suppression or Eradication.** See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW for a detailed description of the brown treesnake suppression or eradication program.
- The same potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 780 acres [316 ha] of limestone forest) would be applicable for the Mariana crow and its recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Mariana crow, should it be reintroduced to Guam in the future.

**GUAM RAIL.** The Guam rail is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the rail is reasonably certain to occur and it is likely to be exposed to
the effects of the action. There are currently neither projected dates for re-introduction of the rail, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the rail is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative E, impacts to the rail would be limited to recovery prospects. If rails are reintroduced and exposed to construction activities under Alternative E, they may be disturbed (DON 2014).

Although the rail no longer occurs on Guam, approximately 507 acres (205 ha) of rail recovery habitat would be removed due to proposed construction activities at Finegayan and AAFB under Alternative E (Table 4.5.8-6). This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

Although this loss of recovery habitat on Guam would not preclude the recovery of the rail should it be reintroduced to Guam in the future, it would reduce the total number of rails that the island can support. Given this loss of recovery habitat, there would be significant but mitigable impacts to the recovery of the Guam rail.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct and indirect long-term impacts of proposed construction activities on the recovery of the Guam rail with implementation of Alternative E. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

Potential Mitigation Measures

- **Brown Treesnake Suppression or Eradication.** See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW for a detailed description of the brown treesnake suppression or eradication program.
- The same potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 780 acres [316 ha] of limestone forest) would be applicable for the Guam rail and its recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated
benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Guam rail, should it be reintroduced to Guam in the future.

GUAM MICRONESIAN KINGFISHER. The kingfisher is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the kingfisher is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the kingfisher, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the kingfisher is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative E, impacts to the kingfisher would be limited to recovery prospects. If kingfishers are reintroduced and exposed to construction activities under Alternative E, they may be disturbed (DON 2014).

Although the kingfisher no longer occurs on Guam, approximately 719 acres (291 ha) of kingfisher recovery habitat would be removed due to proposed construction activities at Finegayan and AAFB under Alternative E (Table 4.5.8-7). This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

Proposed construction activities would result in the loss of 795 acres (322 ha) of kingfisher recovery habitat on Guam. Although this loss of recovery habitat on Guam would not preclude the recovery of the kingfisher should it be reintroduced to Guam in the future, it would reduce the total number of kingfishers that the island can support. Given this loss of recovery habitat, there would be significant but mitigable impacts to the recovery of the Guam Micronesian kingfisher.

The following BMPs and potential mitigation measures may be implemented to avoid, minimize, and mitigate potential direct and indirect long-term impacts of proposed construction activities on the recovery of the Guam Micronesian kingfisher with implementation of Alternative E. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
Potential Mitigation Measures

- **Brown Treesnake Suppression or Eradication.** See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW for a detailed description of the brown treesnake suppression or eradication program.

- The same potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 780 acres [316 ha] of limestone forest) would be applicable for the kingfisher and its recovery habitat. In particular, the objectives of ungulate management, rodent control, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Guam Micronesian kingfisher, should it be reintroduced to Guam in the future.

As part of the ESA section 7 consultation process, the DON and the USFWS entered into a Memorandum of Agreement (MOA) which would, if the preferred alternative is chosen, facilitate kingfisher conservation goals. In the MOA, the DON agreed to designate approximately 5,234 acres (2,118 ha) under the custody and control of the DoD in northern Guam to a status that will provide durable habitat protection needed to support native habitat restoration and land management for the survival and recovery of the kingfisher. Consistent with the JRM INRMP developed in accordance with Section 101 of the Sikes Act, the DON agreed to actively restore native habitat and manage, in collaboration with the USFWS, the 5,234 acres (2,118 ha) consistent with the DoD’s obligations under ESA section 7(a) and the Sikes Act to benefit the survival and recovery of the kingfisher. The DON would work cooperatively with the USFWS to identify, develop and implement specific management activities and projects on these 5,234 acres (2,118 ha) to support the reintroduction and recovery of the kingfisher.

These 5,234 acres (2,118 ha) have been identified by the USFWS as habitat for the kingfisher and needed to offset impacts of the proposed action. The DON and USFWS recognize that the designation of the 5,234 acres (2,118 ha) may also provide a conservation benefit to other ESA-listed species with similar habitat requirements (e.g., Mariana crow, Mariana fruit bat).

**SEA TURTLES.** The green and hawksbill sea turtles potentially nest along the Haputo ERA beach and along Tarague Beach to the west and north of the project areas, respectively (Figures 4.5.8-4 and 4.5.8-5). All cantonment and housing components would be constructed on the upper plateau area of Finegayan and AAFB and would not occur in the vicinity of any potential sea turtle nesting beaches. Construction personnel are issued base passes for official business only within proposed construction areas; these restrictions are specified in construction contracts. Use of Haputo ERA and Tarague Beach are not expected to increase as a result of construction activities; therefore, there would be no impacts from construction personnel to sea turtles that may occur on the Haputo ERA and Tarague Beach.

To avoid and minimize any potential impacts to nesting sea turtles from proposed facility lighting associated with the construction of the cantonment at Finegayan and family housing areas at AAFB, hooded lights would be used to the maximum extent practicable at all new roads and facilities near coastline areas. Illumination of coastline areas would be kept to an absolute minimum. The implementation of the potential mitigation measures described above under Vegetation (i.e., forest enhancement of 780 acres [316 ha] of limestone forest) would also benefit the survival of sea turtles. In particular, the objectives of ungulate management, control/suppression of invasive plants, outplanting of native species, and rodent control. Therefore, there would be no impacts to potential nesting sea turtles.
within the Haputo ERA or Tarague Beach with implementation of the proposed construction activities associated with Alternative E.

**TREE SNAILS.** The three proposed endangered species of tree snails only occur within the Haputo ERA at Finegayan. All cantonment components would be constructed on the upper plateau area of Finegayan and would not occur in the Haputo ERA. Construction personnel are issued base passes for official business only within proposed construction areas; these restrictions are specified in construction contracts. Use of Haputo ERA is not expected to increase as a result of construction activities; therefore, there would be no impacts from construction personnel to tree snails that occur within the Haputo ERA. Therefore, there would be no impacts to tree snails occurring within the Haputo ERA with implementation of the proposed construction activities associated with Alternative E.

The implementation of the potential forest enhancement mitigation measures described above for the Mariana crow would also benefit the survival of tree snails. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species.

**MARIANA EIGHT-SPOT BUTTERFLY.** The Mariana eight-spot butterfly or its two known host plant species have not been reported within the proposed project areas at Finegayan and AAFB. However, given the proximity of the eight-spot butterfly area to Finegayan (see Figure 4.5.8-4) and the high mobility of the species, the species is likely to occur within the larger Finegayan and AAFB areas.

Some species of tropical butterflies have well-developed ears on their wings and can detect sounds at the same frequencies that humans can hear. It is hypothesized that the butterflies are listening to the flight sounds or foraging calls of predatory birds (Lane *et al.* 2008; Yack 2012). Given the low numbers of forest birds currently on Guam due to the brown treesnake, masking of the flight sounds or foraging calls of predatory birds due to noise from proposed construction activities would not make eight-spot butterflies more susceptible to predation.

With implementation of appropriate BMPs to avoid and minimize potential impacts to eight-spot butterflies (e.g., pre-construction butterfly and host plant surveys within the proposed construction footprint and salvage/relocation of host plants, larvae or eggs; see Section 2.8), there would be less than significant impacts to the Mariana eight-spot butterfly with implementation of proposed construction activities associated with Alternative E. In addition, implementation of the potential mitigation measures described above under *Vegetation* (i.e., forest enhancement of 780 acres [316 ha] of limestone forest) would also benefit the survival the eight-spot butterfly. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species, including eight-spot butterfly host plants.

**SERIANTHES TREE.** Although individual *Serianthes* trees do not occur within the impacted areas of Alternative E, approximately 648 acres (262 ha) of *Serianthes* recovery habitat would be removed due to proposed construction activities at Finegayan and AAFB under Alternative E (Table 4.5.8-8). This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.
Table 4.5.8-8. Summary of Permanent Construction-Related Impacts to *Serianthes* Recovery Habitat with Implementation of Cantonment/Family Housing Alternative E

Although this loss of recovery habitat would not preclude the recovery of *Serianthes* on Guam, given the loss of *Serianthes* recovery habitat, there would be significant but mitigable impacts to the recovery of *Serianthes* on Guam.

The following BMPs and potential mitigation measures may be implemented to avoid, minimize, and mitigate potential direct long-term impacts of proposed construction activities on the recovery of *Serianthes* with implementation of Alternative E. Final mitigation measures would be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

**Potential Mitigation Measures**

The same potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 780 acres [316 ha] of limestone forest) would be applicable for *Serianthes* recovery habitat. In particular, the objectives of ungulate management, rodent control, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for *Serianthes*. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

**TABERNAEMONTANA ROTENSIS.** Approximately four clusters of the SOGCN T. rotensis are located within the Alternative E impacted areas, primarily within or adjacent to the proposed utility corridors on AAFB (see Figure 4.5.8-2). Under Alternative E, all *T. rotensis* would be avoided to the maximum extent practicable during proposed construction activities. In addition, high-value (both biologically and culturally) plant species such as *T. rotensis* seedlings and saplings could be salvaged during construction activities and translocated to suitable habitat on AAFB (see Section 2.8). Therefore, with implementation of these BMPs (e.g., avoidance, or salvage and translocation), there would be less than significant impacts to *T. rotensis* with implementation of the proposed construction activities associated with Alternative E.

**CYCAS MICRONESICA.** There are no known *C. micronesica* within the proposed impacted areas associated with Alternative E. With implementation of appropriate BMPs to avoid and minimize potential impacts to cycads (e.g., pre-construction surveys within the proposed construction footprint and salvage/relocation of
plants), there would be less than significant impacts to *C. micronesica* with implementation of proposed construction activities associated with Alternative E.

**Dendrobium guamense** and **Tuberosladium guamense**. There is a known single occurrence of each species within the northeastern portion of Finegayan. Both species would be salvaged to the maximum extent practicable and translocated to suitable habitat (see Section 2.8). With the implementation of BMPs, such as potential translocation of *D. guamense* and *T. guamense* to suitable habitat, there would be less than significant impacts to both species with implementation of the construction activities associated with Alternative E. In addition, the implementation of the potential mitigation measures under the *Vegetation* section above would also benefit the survival of these orchid species. In particular ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures.

**Special-Status Species: Guam-Listed and SOGCN**

**Micronesian Starling.** The Micronesian starling is present in an existing housing area (see Figure 4.5.8-5) that would be redeveloped to accommodate the new housing area on AAFB. During proposed construction and demolition activities, some Micronesian starlings would relocate to other suitable areas on AAFB, particularly to the north and south of the proposed family housing area. To the maximum extent practicable, the mature palm trees that starlings use for nesting and roosting within the existing housing area would not be removed during the proposed construction activities. Construction and demolition would also occur in phases, thereby not impacting the entire starling population within the existing housing area at one time. After construction, starlings could return to the new cantonment/family housing area. It is also expected that the new cantonment/family housing area may potentially increase the area of suitable habitat on AAFB by increasing potential nesting habitat (i.e., man-made structures, palm trees, areas with brown treesnake control). Therefore, as the loss of a portion of existing Micronesian starling habitat on AAFB would be temporary and there would be an increase in starling habitat during and after construction, there would be less than significant impacts to the Micronesian starling with implementation of proposed construction activities associated with Alternative E.

**White-throated Ground Dove.** Although considered extirpated from Guam since the 1980s, the white-throated ground dove has been observed on AAFB on rare occasions (JRM *et al.* 2012a, 2012b; NAVFAC Marianas 2013b). The primary cause of its extirpation and lack of reestablishment on Guam is due to predation by the brown treesnake (GDAWR 2006). It has not been reported in the proposed impacted areas associated with Alternative E, only in other areas on AAFB including the MSA and the southeastern corner of AAFB. Therefore, there would be no impacts to the white-throated ground dove with implementation of the construction activities associated with Alternative E.

**Moth Skink and Pacific Slender-toed Gecko.** The moth skink and Pacific slender-toed gecko were detected in northeastern corner of Finegayan and within a proposed utility corridor along the south-central area of AAFB within secondary limestone forest that would be directly impacted under Alternative E (see Figures 4.5.8-4 and 4.5.8-5). Construction activities associated with Alternative E would result in the loss of approximately 857 acres (347 ha) of occupied limestone forest habitat for both the skink and gecko. This loss of occupied limestone forest habitat for both the skink and gecko would be a significant but mitigable impact.

The following BMPs and potential mitigation measures may be implemented to avoid, minimize, and mitigate potential direct long-term impacts of proposed construction activities on the moth skink and
slender-toed gecko with implementation of Alternative E. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2 under Construction. Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

Potential Mitigation Measures

The potential forest enhancement mitigation measures described above in the Vegetation section would also result in a conservation benefit to the moth skink and slender-toed gecko. The proposed brown treesnake research and suppression measures discussed above under the Mariana crow may also benefit the skink and gecko. See the potential mitigation discussions for the Mariana crow, Micronesian kingfisher, and the Guam rail for more information. No additional impacts to other Guam-listed species and SOG-CN from construction beyond those previously described for Alternative A (see Section 4.1.8.2) would occur under Alternative E. Therefore, there would be less than significant impacts to Guam-listed species and SOG-CN with implementation of proposed construction activities associated with Alternative E.

Operation

Operational impacts would only occur for the proposed cantonment at Finegayan and housing at AAFB. Operational requirements for the proposed utilities would require only periodic, limited maintenance activities along established utility corridors and impacts to biological resources would be less than significant. Consequently, only the potential operational impacts at the proposed Finegayan cantonment and AAFB housing area are evaluated below.

Vegetation. With implementation of BMPs and potential mitigation measures (see Section 2.8), including invasive species outreach and education, ongoing implementation of standard DON biosecurity protocols regarding detection and management of non-native species, and applicable elements of the SIP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of the cantonment and housing area under Alternative E is considered unlikely. Therefore, there would be less than significant impacts to vegetation with operation of the proposed cantonment at Finegayan and housing area at AAFB under Alternative E.

Terrestrial Conservation Areas. After construction of the cantonment and housing areas under Alternative E, approximately half of the remaining designated Overlay Refuge area on Finegayan would be developed, while the majority of remaining designated Overlay Refuge lands on AAFB would remain undeveloped. Therefore, operational activities of the cantonment under Alternative E are expected to result in less than significant impacts to the remaining Overlay Refuge lands on Finegayan and there would be no impact to Overlay Refuge lands with operation of the proposed housing area at AAFB.

All cantonment components would be located on the upper plateau area of Finegayan and not within the Haputo ERA. However, potential increased usage of the Haputo ERA by military and civilian personnel
associated with the proposed cantonment and housing facilities at Finegayan would result in significant but mitigable impacts to the Haputo ERA. The following potential mitigation measures may be implemented to mitigate potential direct, long-term impacts of proposed operational activities on the Haputo ERA with implementation of Alternative E.

Potential Mitigation Measures

The following measures may be implemented to mitigate potential direct, long-term impacts of proposed operational activities on the Haputo ERA with implementation of Alternative E.

- Fencing of the Haputo ERA access trail to control and manage access.
- Development and installation of informational and educational signage.
- Development of educational materials for military and civilian personnel on the sensitive biological resources within the Haputo ERA.
- Monitoring of visitor use.

An ERA is established to conserve and protect characteristic or outstanding botanical, ecological, geological, and scenic features or processes and where current natural conditions are maintained. These conditions are ordinarily achieved by allowing natural, physical, and biological processes to prevail without human intervention. Fencing to manage access would assist in maintaining the characteristics and integrity of the Haputo ERA and would prevent overuse and potential damage to terrestrial biological resources. These measures are consistent with the goals and objectives of the Haputo ERA Management Plan (NAVFAC Marianas 2010).

Wildlife - Native Species. Potential impacts to wildlife were evaluated in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.2.1: North, page 10-101) for a similar proposed action but impacting a larger area, and were found to be less than significant.

No additional impacts to native wildlife species from operations at Finegayan beyond those previously described for Alternative A (see Section 4.1.8.2) would occur under Alternative E. Lighting along the perimeter of the cantonment and housing areas would be hooded or shielded to the maximum extent practicable to prevent unnecessary light beyond operational areas. Proposed operational activities and associated movement of materials onto and off of Guam could increase the potential for the spread of existing or introduction of new non-native invasive species. To prevent the inadvertent spread of non-native species on Guam or to other locations off of Guam, the DON would implement standard biosecurity measures (e.g., brown treesnake interdiction measures, outreach/education, and 1-year post-construction monitoring to evaluate effectiveness of HACCP) into operational procedures and activities. Therefore, there would be less than significant impacts to wildlife due to proposed operation of the cantonment and housing areas under Alternative E.

However, the following BMPs would be implemented to avoid and minimize potential indirect, long-term impacts of proposed operational activities on native wildlife with implementation of Alternative E.

Best Management Practices

- *Biosecurity Outreach and Education*. See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
With implementation of these BMPs, including ongoing implementation of standard DON biosecurity protocols regarding detection and management of non-native species and 1-year post-construction monitoring to evaluate effectiveness of HACCP, the risk of the introduction and establishment of new or spread of existing non-native species on Guam is substantially reduced.

Continued implementation of the potential mitigation measures under the Construction, Vegetation and Special-status Species sections above would also benefit native wildlife species and habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species. The implementation of the potential mitigation measures under the Terrestrial Conservation Areas section above would also benefit native wildlife species. Fencing to manage access would assist in maintaining the characteristics and integrity of the Haputo ERA and would prevent potential disturbance to native wildlife species within the Haputo ERA. Therefore, there would be less than significant impacts to native wildlife species related to the introduction and establishment of non-native species due to operational activities associated with Alternative E.

Special-Status Species: Federal ESA-Listed and Proposed Species

MARIANA FRUIT BAT. Potential impacts to the Mariana fruit bat from operational activities are based on the distances from operations that are likely to cause disturbance to this species (e.g., noise, lighting, and general human disturbance). These are the same distances that were previously discussed for construction impacts. This area of fruit bat recovery habitat would continue to be impacted from operational activities of the cantonment area at Finegayan and housing area at AAFB after construction activities have ceased.

Operation of the proposed cantonment and housing areas under Alternative E would result in significant but mitigable impacts to fruit bats due to potential direct disturbance (e.g., noise, lighting, and general human disturbance) to fruit bats within 150-m of the cantonment/family housing area. The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential long-term impacts of proposed operational activities on the Mariana fruit bat with implementation of Alternative E.

Best Management Practices

- **Lighting Installation.** Lighting would be designed to meet minimum safety and AT/FP requirements. Hooded lights would be used to the maximum extent practicable at all roads and facilities adjacent to fruit bat habitat. Illumination of forest would be kept to an absolute minimum.

- With implementation of BMPs (see previous discussion of construction impacts under Vegetation), including ongoing implementation of standard DON and commercial biosecurity protocols (e.g., Port of Guam, A.B. Won Pat International Airport) regarding detection and management of non-native species, invasive species outreach and education, 1-year post construction monitoring to evaluate effectiveness of HACCP, and applicable elements of the SIP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of the proposed cantonment/family housing under Alternative E is considered unlikely.

Potential Mitigation Measures

- Continued implementation of the potential mitigation measures under the Construction, Vegetation and Special-status Species sections above would also benefit the Mariana fruit bat and recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species. The implementation of the potential mitigation measures
under the Terrestrial Conservation Areas section above would also benefit the fruit bat and recovery habitat. Fencing to manage access would assist in maintaining the characteristics and integrity of the Haputo ERA and would prevent potential disturbance to fruit bats within the Haputo ERA.

**Mariana Crow, Guam Rail, and Guam Micronesian Kingfisher.** These species are extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of these species is reasonably certain to occur and the species are likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of these species, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the crow, rail, and kingfisher are successfully re-introduced and then have the potential to be exposed to cantonment and housing operational activities under Alternative B, there would be no impact to these species. If the species are reintroduced and exposed to cantonment and housing operational activities under Alternative E, they may be disturbed.

**Sea Turtles.** Potential impacts to sea turtles were evaluated for a similar, but larger, proposed action in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.2.1: North, NCTS and South Finegayan; page 10-118), and were found to be less than significant and would continue to be less than significant with implementation of Alternative E.

As discussed previously under construction impacts, to avoid and minimize any potential impacts to nesting and potential hatchling sea turtles from proposed facility lighting at Finegayan and AAFB, hooded lights would be used to the maximum extent practicable at all new roads and facilities near coastline areas. Illumination of coastline areas would be kept to an absolute minimum.

Increased recreational use of Tarague Beach by military and civilian personnel associated with the proposed housing facilities at AAFB could potentially impact sea turtles using the beach and nearshore waters. The implementation of the potential mitigation measures under the Construction, Vegetation and Terrestrial Conservation Areas sections above would benefit the survival of sea turtles (e.g., reducing erosion, reducing nest predation by rodents). In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Free-roaming pets are not permitted on DON installations. All pets must be either kept indoors or, when outside, on a leash and collar or within a cage or fenced yard. This policy would prevent potential impacts to nesting sea turtles from harassment, injury or mortality from free-roaming pets. Pets are not permitted in the Haputo ERA. Fencing to manage access would assist in maintaining the characteristics and integrity of the Haputo ERA and would prevent potential disturbance to nesting sea turtles that may potentially use Haputo Beach.

Given the low probability of sea turtle nesting at Haputo Beach combined with implementation of potential mitigation measures for Vegetation, Terrestrial Conservation Areas and Wildlife-Native Species, impacts resulting from the proposed action would be less than significant to nesting sea turtles at Haputo Beach within the Haputo ERA and Tarague Beach with implementation of the operational activities associated with Alternative E.

**Mariana Eight-Spot Butterfly.** The Mariana eight-spot butterfly and its host plants are known to occur within the Haputo ERA, but not within the impacted areas of Finegayan or the housing area on AAFB (see Figure 4.5.8-4). With the exception of periodic fence maintenance in the northern portion of
Haputo ERA near the known butterfly area, there would be no operational impacts to butterflies or host plants with implementation of Alternative E.

**Tree Snails.** Three species of proposed endangered tree snails are present along the coast in the Haputo ERA. Potential impacts to tree snails at Haputo ERA were evaluated for a similar, but larger proposed action in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.2.1: North, page 10-118). Potential impacts to tree snails at the Haputo ERA due to operations associated with Alternative E would be less than significant. Implementation of the potential mitigation measures discussed below would provide additional benefits to tree snails.

The implementation of the potential mitigation measures under the Vegetation and Terrestrial Conservation Areas sections above would also benefit tree snails. In particular, the objectives of ungulate management, rodent control, control/suppression of invasive plants, and outplanting of native species proposed under the potential forest enhancement mitigation measures. There is the potential for impacts to tree snails within the Haputo ERA from disturbance of vegetation and collecting and handling of tree snails due to increased usage of the ERA by military and civilian personnel associated with the proposed cantonment and housing facilities at Finegayan. Fencing to manage access would assist in maintaining the characteristics and integrity of the Haputo ERA and would prevent potential disturbance to tree snail species and their habitat within the Haputo ERA.

**Tabernaemontana Rotensis and Cycas Micronesica.** There would be no impacts to *T. rotensis* and *C. micronesica* due to operations associated with Alternative E. The implementation of the potential mitigation measures under the Terrestrial Conservation Areas section above would also benefit special-status plant species. Fencing to manage access would assist in maintaining the characteristics and integrity of the Haputo ERA and would prevent potential disturbance to special-status plant species within the Haputo ERA.

**Dendrobium Guamense and Tubulabium Guamense.** After proposed construction of Alternative E facilities and infrastructure, there would be no known occurrences of either species within Finegayan or AAFB support areas associated with Alternative E. Therefore, there would be no impacts to both species with implementation of Alternative E operations.

**Special-Status Species: Guam-Listed and SOGCN**

No additional impacts to Guam-listed species and SOGCN from operations beyond those described for Alternatives A and C would occur under Alternative E. There would be no impacts to the moth skink or slender-toed gecko due to operations associated with Alternative E. The implementation of the potential mitigation measures under the Terrestrial Conservation Areas section above would also benefit the skink and gecko. Fencing to manage access would assist in maintaining the characteristics and integrity of the Haputo ERA and would prevent potential disturbance to these species and their habitat within the Haputo ERA.

Micronesian starlings are adapted to human presence and associated activities based on their ability to nest and forage in housing areas. Therefore, there would be no operational impacts to starlings under Alternative E.

Although considered extirpated from Guam, the white-throated ground dove is observed on AAFB on rare occasions (JRM et al. 2012a, 2012b; NAVFAC Marianas 2013b). The white-throated ground dove has not been reported in the Alternative E impacted areas. Therefore, there would be no impacts to the white-throated ground dove due to operations associated with Alternative E.
Therefore, there would be less than significant impacts to Guam-listed species and SOGCN with the operation of the cantonment area at Finegayan and family housing area at AAFB under Alternative E.

4.5.9 Marine Biological Resources

4.5.9.1 Affected Environment

Under Alternative E, the affected environment for marine biological resources is as described for Alternative A (Section 4.1.9) and Alternative C (Section 4.3.9). In addition, an extensive discussion of the affected environment for marine biological resources surrounding Guam is provided in the 2010 Final EIS (Volume 2, Chapter 11: Marine Biological Resources, Section 11.1: Affected Environment, pages 11-1 to 11-68). Under Alternative E, the family housing would be constructed at AAFB in existing disturbed areas and would be further away from the coast than the family housing location under Alternative A. The cantonment at Finegayan would be located at the same location as for Alternative A.

4.5.9.2 Environmental Consequences

The environmental consequences for marine biological resources in the vicinity of Alternative E would be similar to those previously described for Alternatives A and C in Sections 4.1.9.2 and 4.3.9.2, respectively. Because the family housing under Alternative E would be located inland at AAFB and not in proximity to any recreational beaches (e.g., Haputo Beach) compared to Alternative A, the potential for any impact to marine biological resources would be reduced during construction and operation. The only anticipated indirect impact to all marine biological resources from project operations is associated with temporary increased wastewater discharge from the Northern District WWTP. Mitigation to address this impact would be the same for Alternative E as described for Alternative A in Section 4.1.9.2. With such mitigation, the impact to marine biological resources via water quality could be beneficial in the long-term because wastewater discharge from the Northern District WWTP would improve over existing conditions with treatment system upgrades. However, during the interim period of change when the effluent discharged from the Northern District WWTP would continue to not meet Guam Water Quality Standards, the proposed action may indirectly impact marine biological resources via water quality, but effects would be temporary and less than significant as described for Alternatives A and C in Sections 4.1.9.2 and 4.3.9.2, respectively.

In accordance with the Magnuson-Stevens Fishery Conservation and Management Act, the DON initiated informal consultation with the NOAA’s NMFS Pacific Islands Regional Office, Habitat Conservation Division in May 2014 to determine the potential effects of construction and operations of DON’s preferred alternatives (Alternatives E and 5) on EFH. NMFS reviewed the 2014 Draft SEIS on Guam and CNMI Military Relocation (2012 Roadmap Adjustments) and supplementary information provided by the DON during the course of the EFH consultation.

NMFS determined that adverse effects to EFH would occur unless recommended conservation measures were implemented. NMFS identified seven conservation recommendations to avoid and minimize impacts to EFH. The NMFS EFH effects determination letter of April 27, 2015 containing the complete list of recommendations and the DON’s response to the determination letter are located in Vol. 2 Appendix F.5. NMFS’ recommended conservation measures are summarized below.

- The DON should commit to ensure that the Northern District WWTP is upgraded to meet Guam Water Quality Standards (GWQS) with an emphasis on orthophosphate, nitrate-nitrogen, and ammonia concentrations. The DON should encourage GWA to reduce nutrient levels even further as the GWQS are still above recommended levels of nitrate and orthophosphate discharges for coral reef habitats.
• The DON should, to the greatest extent practicable, minimize stormwater runoff and prevent increases in the amount of water discharged through freshwater seeps into nearshore coastal waters for each project component.

• The DON should further examine the fate of stormwater for these project components, particularly the Finegayan Cantonment and NWF LFTRC, to determine whether stormwater practices affect sensitive nearshore reefs such as the HAPCs at Haputo ERA and the Ritidian Unit of the Guam NWR through seeps.

• The ROD should clearly identify funding and provide minimal guidelines for programs to minimize impacts from training, recreation, and fishing activities for Marine Corps personnel.

• Ensure that each Marine Corps unit assigned to Guam irrespective of duration and deployment status will institute a physical training awareness and operational guidance that identifies appropriate physical training areas as well as identify sensitive areas that are off-limits for such activities in coordination with installation and regional resource management plans.

• Develop methods to minimize fishing impacts by reducing take of fish species from key functional groups and rare species. This could include a ban for DoD personnel on use of destructive methods of fishing including for species of local concern such as humphead wrasse and green humphead parrotfish.

• The DON should provide a commitment to develop and implement a detailed and comprehensive Adaptive Management Plan that defines watershed management and erosion control mechanisms that will be adopted based on current best available information and involve a protocol articulating the framework to include assessing and mitigating cumulative impacts.

On December 10, 2014, pursuant to section 7(a)(2) of the ESA, the DON requested informal consultation with NMFS Pacific Islands Regional Office regarding the effects of the proposed action on ESA-listed marine species: the threatened scalloped hammerhead shark and four species of threatened coral (Acropora globiceps, Acropora retusa, Pavona diffusa, and Seriatopora aculeata). Based on further consultation with NMFS, the DON determined that only three of these recently listed coral species could occur in the vicinity of the proposed action (Acropora globiceps, Acropora retusa, and Seriatopora aculeata) and accordingly, the DON requested informal consultation to address potential effects to these three recently listed species.

The DON requested informal consultation for two separate proposed action elements, which may have the potential to affect the scalloped hammerhead shark and the three species of threatened coral identified above:

• The effects of the projected increase of effluent from the Northern District WWTP outfall, a GWA facility.

• The effects of constructing the Amphibious Vehicle Laydown Area (AVLA) in Inner Apra Harbor.

The DON determined that the projected increase of effluent from the Northern District WWTP outfall may affect, but is not likely to adversely affect Acropora globiceps, Acropora retusa, and Seriatopora aculeata, and the scalloped hammerhead shark because the effects are insignificant.

The AVLA includes a vehicle ramp which is the only in-water project not completed from the original 2010 EIS and associated ESA section 7 consultation with NMFS. The DON determined that the AVLA project may affect, but is not likely to adversely affect the scalloped hammerhead shark, because the effects are discountable. At the request of NMFS, on April 13, 2015 the DON provided additional detailed information about the proposed action and potential conservation and mitigation measures (see
Appendix F.5). Consultation with NMFS concluded with a letter of concurrence on May 18, 2015 (see Appendix F.5). NMFS considered the information in the DON’s EIS/OEIS (2010), the Draft SEIS (2014), and consultation requests, as well as the best scientific information available about the biology and expected behaviors of the ESA-listed marine species and agreed with the DON conclusion that the proposed action is not likely to adversely affect the scalloped hammerhead shark or the ESA-listed corals.

NMFS also agreed that the proposed action would have no effect on critical habitat. NMFS provided in their letter of concurrence five conservation recommendations that they deemed prudent. The DON will consider adoption of one or more of these conservation recommendations and will address them in the ROD for this proposed action.

4.5.10 Cultural Resources

4.5.10.1 Affected Environment

The following discussion summarizes previous cultural resources studies and known historic properties and other cultural resources within the area of potential cultural resource impacts associated with Alternative E. The discussion below addresses historic properties, as defined in the NHPA, and resources of cultural importance as defined under NEPA. The discussion refers to the terms direct effects and indirect effects to historic properties as defined under the NHPA, and impacts to other cultural resources as defined under NEPA (see Section 3.10.3.2). The section is organized to address cultural resources for the cantonment/family housing, followed by discussion of the same resource types for off-site utilities and school expansions associated with this alternative. If this alternative is selected for implementation, the information presented here would be augmented by reviews consistent with the 2011 PA, which provides overall NHPA Section 106 compliance and addresses other cultural resource issues. Refer to Section 3.10 for a detailed description of the 2011 PA. Additionally, some built properties in this section are covered by Program Comments executed by the ACHP, which resolve Section 106 responsibilities for certain DoD facilities. See Chapter 3, Section 3.10 for more information on definitions and procedures.

Alternative E is located in two locations on the northern portion of Guam: Finegayan and AAFB. The cantonment area of Alternative E includes the same area as the proposed cantonment for Alternative A. The housing area for Alternative E would be located at the current AAFB family housing area as discussed under Alternative C.

Located on the northwestern side of Guam, Finegayan is a telecommunications installation that was first established during the 1950s. The installation includes radio frequency systems and terrestrial-based fiber optic cables. Alternative E would construct and operate administrative facilities and associated utilities (see Figure 2.4-13 in Chapter 2 of this SEIS) for the cantonment.

AAFB is located on the northern plateau area of Guam. It includes the main active airfield and an array of operations, maintenance, and community support facilities. The central third of the installation is a MSA. The western third is NWF, a WWII-era airfield used for fixed-wing aircraft and helicopter training and various field exercises and bivouacs. Alternative E would construct and operate administrative and housing areas, community support facilities (e.g., schools, child development center, community center), and associated utilities (see Figure 2.4-13 in Chapter 2 of this SEIS).
The affected environment for cultural resources associated with Alternative E is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 12: Cultural Resources, Section 12.1.2.2: Finegayan, pages 12-16 to 12-19 and Volume 2, Chapter 12: Cultural Resources, Section 12.1.2.1: Andersen AFB, pages 12-9 to 12-16), which were based on surveys of the PDIAs completed at that time. The description of the affected environment provided here has been updated with new information from recent archaeological and architectural investigations supporting other projects. To determine whether information is from an existing reference (such as the 2010 Final EIS or other cultural resource studies) or collected during in-fill studies conducted in support of this SEIS, refer to dates in the reference column in each table for the archaeological sites. Information for the architectural resources was derived from the internet Navy Facilities Asset Data Store (iNFADS).

Surveys conducted to support the 2010 Final EIS included the PDIA for Alternative E. Those previous investigations included intensive archaeological surveys (Athens 2009; Welch 2010), architectural inventories (Welch 2010; SEARCH 2013), potential TCP studies (Griffin et al. 2010), and oral histories (Welch 2010). In addition to these surveys and other past surveys (Grant et al. 2007), an intensive archaeological survey of 993 acres (402 ha) and an architectural inventory was conducted for this SEIS (Dixon et al. 2014). The previous investigations provide a comprehensive inventory of cultural resources and TCPs occurring within the Alternative E PDIA.

On-site utility corridors associated with Alternative E would be located along the southern boundary of AAFB adjacent to Route 9 (see Figure 2.4-13) and along Route 3 east of Finegayan. Intensive archaeological surveys of the proposed utility line impacted area on AAFB were conducted in 2004 (Yee et al. 2004), 2008 (Athens 2009) and 2010 (Dixon and Walker 2011).

All cantonment/housing alternatives would include construction of off-site utilities along Routes 1, 3, and 9, a water well field at AAFB, and expansion or construction of two schools at Naval Base Guam and AAFB (see Figure 2.4-14). Assessments of potential impacts to cultural resources from construction of utilities along road right-of-ways are based on a reconnaissance survey of portions of the area in 2010 (Dixon et al. 2011b) and a literature review of previous surveys and historic development in the area. Assessments of impacts to cultural resources from the development of a water well field and from the two school expansions are based on in-fill surveys conducted in support of this SEIS (Dixon et al. 2014).

Based on data from previous surveys of the proposed cantonment/family housing area, and utility corridor impacted areas, Table 4.5.10-1 lists 16 known archaeological sites located within PDIA for Alternative E. Of the 16 sites, 7 are considered eligible for listing in the NRHP and include 4 Pre-Contact/Latte Period artifact/ceramic scatters, 1 Pre-Contact/Latte Period habitation site, and 2 historic/First and Second American Administration sites. Nine sites ineligible for listing are comprised of disturbed WWII encampments and Pre-Contact/Latte Period pottery scatter.

**Legend:** GHPI = Guam Historic Properties Inventory; NRHP = National Register of Historic Places; NA = not applicable. NRHP criteria D = eligible for potential to yield information important in prehistory or history.

**Notes:**
- Map numbers are from Welch et al. (2009) and Welch (2010).
- **Revised to match Guam GHPI forms dated May 28, 2014.**
- ***The Guam SHPO concurs with this recommendation (Guam SHPO correspondence dated July 2, 2014 [RC2013-0853]).***

Two NRHP-eligible archaeological sites, located on AAFB, have been identified within the PDIA for Alternative E on-site utility corridors (see Figure 2.4-5; Table 4.5.10-2). However, data recovery for both sites has been performed as mitigation for a previous project (Eakin et al. 2012). No TCPs have been identified in the PDIA for this alternative.

Legend: NRHP criterion D = eligible for potential to yield information important in prehistory or history.

Note: *Data recovery excavations were conducted at both sites (Eakin et al. 2012), which determined that neither site had an intact subsurface cultural deposit.
**Revised to match Guam GHPI forms dated May 28, 2014.
***The Guam SHPO concurs with this recommendation (Guam SHPO correspondence dated July 2, 2014 [RC2013-0853]).

There are 974 architectural properties, constructed between 1953 and 2008, within the PDIA for Alternative E (Table 4.5.10-3). These buildings and structures include barracks, administrative facilities, and recreational facilities. Thirty-nine buildings are bachelor housing covered under the Program Comment for Cold War Era Unaccompanied Personnel Housing (ACHP 2006; see Chapter 3.10.3 for more information on the Program Comments). A total of 766 buildings are family housing and are covered under the Program Comment for Wherry and Capehart Era Family Housing at Air Force and Navy Bases (ACHP 2004). Seventeen buildings are housing support facilities, including garages and other facilities, all of which are covered under the Program Comment for Wherry and Capehart Era Family Housing at Air Force and Navy Bases (ACHP 2004). Four buildings and structures are support facilities (recreational and hydrologic facilities) that are greater than 50 years in age that have not been evaluated. Five wells and three buildings of unknown age have also not been evaluated for NRHP-eligibility. If Alternative E were selected, any unevaluated properties would be evaluated under the procedures identified in the 2011 PA. One-hundred and thirty-eight buildings have been determined ineligible for listing in the NRHP, including 74 buildings that are less than 50 years old and do not meet the exceptional significance threshold required under NRHP Criteria Consideration G. The 2011 PA includes procedures for the identification of historic properties, as specific projects are developed, through consultation with the Guam SHPO and the public.

Certain off-site utility improvements are common to all of the cantonment/family housing alternatives. In addition to the cantonment/family housing and utility corridor areas, Alternative E would include construction of off-site utilities, a water well field, and expansion or construction of two schools. One site, T-H-1, is within the off-site utility corridor. This site is not eligible for listing in the NRHP. No architectural properties or TCPs have been identified within the off-site utilities PDIA.

In addition to the cantonment/family housing and utility corridor areas, Alternative E would include construction of off-site utilities, a water well field, and expansion or construction of two schools. Nine NRHP-eligible archaeological sites and 15 sites not considered eligible for listing in the NRHP have been identified in these areas (see Alternative A, Table 4.1.10-4 and 4.1.10-5). As under Alternative A, one structure within the well development area on AAFB is eligible for listing in the NRHP, four structures are not eligible, and six structures are unevaluated. (No architectural properties or TCPs have been identified within the off-site utilities potential impacted area).

*Note: Information on type, number, and date of construction from iNFADS.*

Under Alternative E, the Andersen Middle School facility would be repurposed as an elementary school and expanded at its current site, and a new middle school would be constructed. This area is within the AAFB cantonment/family housing potential direct impacted area. The expansion of the DoDEA High School would involve construction at the Naval Hospital site in central Guam. No NRHP-eligible sites, architectural properties, or TCPs have been recorded in this area.
4.5.10.2 Environmental Consequences

Construction

Construction activities associated with Alternative E may adversely affect historic properties. Final determinations of effect would occur under the 2011 PA. Following is a discussion of potential adverse effects for purposes of this analysis. Excavation and soil removal associated with buildings and on-site utility construction could adversely affect seven known NRHP-eligible archaeological sites, including Pre-Contact/Latte Period artifact scatters and other sites (see Table 4.5.10-1 and Table 4.5.10-2). In addition, two of sites (GHPI Numbers 66-08-2551 and 66-08-2552) have been previously mitigated via archaeological data recovery conducted in consultation with SHPO (Eakin et al. 2012).

Construction at Finegayan would also require the demolition of 24 buildings (see Table 4.1.10-7). Of these 24 buildings in the PDIA, 16 are covered under the Program Comment for Cold War Era Unaccompanied Personnel Housing (ACHP 2006), 7 are not eligible, and 1 (facility number 209) is not evaluated. Consistent with the 2011 PA, final determinations of eligibility, including the one unevaluated property, and assessment of effect would be completed in conjunction with project-specific reviews, if this alternative is selected.

Construction at AAFB would also require the demolition of 832 buildings (Table 4.5.10-4). Of these 832 buildings and structures, two buildings are covered under the Program Comment for Cold War Era Unaccompanied Personnel Housing (ACHP 2006), and 766 are covered under the Program Comment for Wherry and Capehart Era Family Housing at Air Force and Navy Bases (ACHP 2004). Fifty-eight buildings and structures are not eligible, and seven are unevaluated.

*Facilities that would be demolished for the Andersen Middle School expansion.

**Legend:**  
KW = kilowatt

The Program Comments resolve NHPA Section 106 requirements for demolition of 784 buildings. As 65 buildings and structures are not eligible for listing in the NRHP, the demolition of these buildings under Alternative E would be consistent with a finding of no historic properties affected. Consistent with the 2011 PA, final determinations of eligibility, including the seven unevaluated properties, an assessment of effect would be completed in conjunction with project-specific reviews, if this alternative is selected.

Excavation and soil removal associated with the construction of off-site utilities and expansion of two schools could adversely affect 9 known NRHP-eligible archaeological sites (see Alternative A, Tables 4.1.10-4 and 4.1.10-5) and 1 NRHP-eligible structure. Six structures that are unevaluated could also be adversely affected by construction.
In addition, construction at Finegayan and AAFB has the potential to directly impact culturally important resources that are not historic properties, but may be considered under NEPA. The project would require the removal of limestone forest where culturally important natural resources may be present. The 2011 PA contains measures for coordinating with the SHPO and concurring parties to contact traditional natural healers, herbal practitioners, and traditional artisans regarding identification and disposition of these important resources (see 2010 Final EIS, Volume 2: page 2-10; Volume 9, Appendix G, Chapter 4).

**Operation**

Operations associated with Alternative E would not directly affect any historic properties or impact other resources of cultural importance. Indirect adverse effects to known NRHP-eligible archaeological sites due to an increase in population would be minimal as these sites are not adjacent to the cantonment area.

**Summary of Impacts and Potential Mitigation Measures**

Implementation of Alternative E could cause direct, adverse effects to 16 known NRHP-eligible sites and 1 historic structure, which is less than Alternatives A, B, and C, but more than Alternative D. Refer to Section 4.7, Table 4.7-1 for a comparison of cultural resources impacts and potential mitigation measures for each cantonment/family housing alternative. Demolition could also affect 14 buildings and structures that have not been evaluated for listing in the NRHP (see Tables 4.5.10-3 and 4.5.10-4).

Direct impacts could occur to natural resources of cultural importance as a result of limestone forest removal. The 2011 PA includes measures to coordinate with SHPO and concurring parties to address appropriate treatment of these resources.

The 2011 PA, as discussed in Section 3.10.2., establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. Broadly, the 2011 PA includes processes to share information, consider views of the public, and develop mitigation measures when historic properties may be adversely affected. The 2011 PA provides measures for mitigating adverse effects to NRHP-eligible or listed archaeological sites, consulting on new projects and initiating additional identification efforts, and resolving impacts due to loss of access to culturally important natural resources. To the degree possible, direct and indirect impacts to historic properties and other resources of cultural importance would be avoided or minimized during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, Table 4.5.10-5 presents potential mitigation measures to resolve adverse effects to historic properties and reduce impacts to cultural resources resulting from the implementation of Alternative E. With the implementation of these measures and processes as outlined in the 2011 PA, it is expected that significant direct and indirect impacts due to construction, as defined under NEPA, would be reduced to a level below significance.
Table 4.5.10-5. Potential Mitigation Measures for Alternative E for Adverse Effects (NHPA) and Impacts to Other Cultural Resources (NEPA)

<table>
<thead>
<tr>
<th>NHPA Effects</th>
<th>Mitigation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Potential direct adverse effects to 17 historic properties - 16 NRHP-eligible archaeological sites and 1 NRHP-eligible structure</td>
<td>Consistent with the 2011 PA, data recovery is the standard mitigation for historic properties that are strictly archaeological in nature. Accordingly, the DON will submit a mitigation plan to the SHPO, consult with other PA Signatories and Concurring Parties if requested, and submit data recovery reports for SHPO review prior to finalizing mitigation reports. Mitigation also includes preparation of public education and interpretation materials in English and Chamorro using the information developed or data recovered to create a summary of the work completed and a statement regarding the mitigated site’s significance to the regional culture. Additional mitigation would include enforcement of construction contract stipulations and GHPI data form updates as required by the 2011 PA.</td>
</tr>
<tr>
<td>Undetermined effects to 14 unevaluated buildings</td>
<td>If this alternative is selected in the ROD, unevaluated properties that may be affected would be evaluated consistent with the 2011 PA. If determined eligible for listing in the NRHP, appropriate mitigation measures would be developed to resolve any adverse effects.</td>
</tr>
<tr>
<td>Potential direct impacts to culturally important natural resources</td>
<td>Through the 2011 PA process, coordinate with the SHPO and concurring parties to contact traditional natural healers, herbal practitioners, and traditional artisans to provide an opportunity to collect these resources consistent with installation security instructions and safety guidelines.</td>

4.5.11 Visual Resources

4.5.11.1 Affected Environment

A list and description of visual resources at Finegayan and AAFB is contained in the 2010 Final EIS (Volume 2, Chapter 13: Visual Resources, Section 13.1.1.2: Affected Environment, pages 13-9 to 13-13 and pages 13-1 to 13-8, respectively). The Finegayan area includes DON communication facilities surrounded by low grasslands, shrubs, and densely forested areas. Wide open vistas from, and into, this area are limited due to the terrain and vegetative canopy. Nevertheless, there are some areas with breaks in the canopy, providing panoramic vistas of natural and man-made features along Route 3.

AAFB is composed of runways, buildings, facilities, and housing areas all surrounded by moderately to heavily vegetated forest. Due to the relatively flat topography and moderate to heavy vegetation, the surrounding communities of Dededo and Yigo have limited views into AAFB. One exception to this is the views afforded from Mount Santa Rosa (Photos 4.3.11-1 and 4.3-11-2). From this point, sweeping 360-degree views can be seen of the entire north area, including distant views of AAFB facilities and surrounding landscape.

4.5.11.2 Environmental Consequences

Construction

Short-term direct impacts to existing public views would result from the presence of construction equipment, then would cease to continue after construction. Therefore, there would be less than significant impacts on visual resources at both the Finegayan cantonment site and the AAFB family housing site.

Operation

The operational impacts for the Finegayan cantonment under Alternative E would be less than significant, as described for Alternative A, Section 4.1.11.2. In summary, the proposed facilities would not be visible
from recognized viewpoints, vistas, or overlooks. While some features would be publicly visible from roadways, no recognized view corridors or sensitive receptors would be impacted. The new base features would be designed to be consistent with the 2011 Installation Appearance Plan so that the visible elements are consistent in design. In addition, the Haputo ERA Management Plan requires a no construction buffer zone of 100 feet (30.5 m) from the ERA boundary. There would also be an additional buffer of approximately 440 feet (134 m) from the cliffline to the Haputo Bay shoreline (total of 0.1 mile [0.2 km]).

The visual impacts related to the AAFB family housing would be as described for Alternative C, Section 4.3.11.2. In summary, the operational impacts on visual resources would be less than significant. The existing family housing area would be redeveloped at a greater density than the existing housing but the panoramic views from Mount Santa Rosa would retain the dominant presence of vegetation throughout the region.

All alternatives would have a less than significant impact on visual resources. The visual resource impacts of Alternative E would be as described for Alternatives A and C. Most of the differences in layout would be interior of the installation and not perceived from public roadways.

4.5.12 Ground Transportation

4.5.12.1 Affected Environment

The affected environment for ground transportation resources associated with Alternative E includes transportation facilities internal to the site (on-base roadways and intersections) and entry control facilities. This section addresses existing conditions and assesses how the construction and operation of Alternative E would potentially affect transportation conditions for roadways, transit facilities, and pedestrian and bicycle facilities on-base. Potential ground transportation impacts to off-base (external) roadways are addressed in Section 6.1 of this SEIS.

Roadway Network

As described in Section 4.1.12.1, Ground Transportation, for Alternative A, Finegayan is currently accessible via the existing gate located on Route 3 near Bullard Avenue. Currently, all of the on-base roadways are two lanes (one lane in each direction). Traffic counts at this military access point were conducted in December 2012. Based on the relatively low traffic demand observed at this location, the internal roadways and intersections are expected to operate at acceptable LOS (LOS A, B, C, D, or E) during the weekday a.m. and weekday p.m. peak hours.

As described in Section 4.3.12.1, Ground Transportation, for Alternative C, AAFB has two existing access gates. The Main Gate provides access between Route 1 and Arc Light Boulevard. Arc Light Boulevard is the main roadway on-base and provides an east/west route across the base. The Santa Rosa Gate is located approximately 1.1 mile (1.8 km) southeast of the Main Gate and provides access between Route 15 and Santa Rosa Boulevard. Santa Rosa Boulevard passes through housing areas on-base. All of the base roadways are two lanes (one lane in each direction), with additional separate turning lanes at major intersections. All of the on-base intersections are currently controlled by two- or all-way stop signs. The AAFB Traffic and Safety Engineering Study (AAFB 2009) concluded that most of the on-base intersections were operating at acceptable LOS (LOS A, B, C, D, or E), with the exception of several intersections along Arc Light Boulevard. The study recommended improvements for those intersections.
Transit Network

As described in Section 4.1.12.1, Ground Transportation, for Alternative A and Section 4.3.12.1, Ground Transportation for Alternative C, there is no existing transit service on Finegayan or AAFB. The GRTA operates fixed route and paratransit service. The Blueline 1, servicing Hagåtña, Tamuning, Micronesia Mall, and Tumon, is the nearest fixed route bus line, a distance of approximately 5.6 miles (9.0 km) from Finegayan and approximately 10.5 miles (16.9 km) from AAFB. Paratransit service is provided to all ADA-eligible certified passengers. Paratransit service provides transportation to the nearest fixed route.

Pedestrian and Bicycle Network

As described in Section 4.1.12.1, Ground Transportation, for Alternative A, there are no dedicated pedestrian or bicycle facilities on or near Finegayan. However, shoulders exist along Route 1 and on Route 3, south of Route 28. Typically, the outside lane or shoulder, which is generally unpaved, functions as the pedestrian/bicycle space. As described in Section 4.3.12.1, Ground Transportation, for Alternative C, there is a dedicated pedestrian jogging trail provided along Arc Light Park and Bonins Avenue. No other dedicated pedestrian or bicycle facilities exist on or near AAFB.

Environmental Consequences

4.5.12.2 Environmental Consequences

Potential ground transportation impacts addressed in this section are limited to elements of the proposed action that could affect on-base (internal) roadways. Potential ground transportation impacts to off-base (external) roadways are addressed in Section 6.1 of this SEIS.

Construction

Potential short-term, direct construction impacts generated by the proposed action at Alternative E would be similar to Alternative A (Section 4.1.12.2) and Alternative C (Section 4.1.12.2). Potential impacts to ground transportation resources from construction would be reduced to less than significant levels with implementation of appropriate work zone traffic management strategies and BMPs. Therefore, Alternative E would result in less than significant short-term, direct impacts to on-base (internal) roadways.

Operation

Roadway Network

The Alternative E Finegayan cantonment would be directly accessible from Route 3 and Route 3A. The existing gate would be closed, removed, and replaced. The cantonment area would be located at the north end of the site and would be accessible via a new Main Gate. The new Main Gate would be aligned with the westbound approach of the second roadway south of Potts Junction (i.e., the roadway immediately south of the access road to the Starts Golf Resort). At the north end of the site, a new Commercial/Tactical Vehicle Gate would be constructed on Route 3A. Within Finegayan, a four-lane arterial roadway would extend from the proposed new Main Gate to the Marine Expeditionary Brigade Headquarters. This road would be designed and expected to carry the heaviest traffic volumes, including civilian employee trips from off-base to/from work locations within the cantonment area, as well as trips by military personnel to/from the cantonment and other off-base locations.

The Alternative E AAFB family housing area would be accessed by the existing family housing gate (the Santa Rosa Gate) at the northern end of Route 15, and could also be accessed from the AAFB Main Gate off Route 9. Within AAFB, existing roadways would be utilized to the extent possible. Santa Rosa Boulevard would extend from the Santa Rosa Gate to Carolines Avenue at the north end of the family.
housing area. Santa Rosa Boulevard would be upgraded and would be designed and expected to carry the heaviest traffic volumes; including civilian employee trips from off-base to/from work locations within the family housing area, as well as trips by military personnel to/from the family housing area and other off-base locations. Marianas Boulevard would provide access to residences and facilities to the east and west of Santa Rosa Boulevard. Two existing internal roadways on AAFB, Marianas Boulevard and Carolines Avenue, would connect the family housing area with AAFB.

Traffic between the Alternative E Finegayan cantonment and AAFB family housing would be off-base (external) and is addressed in Section 6.1 of this SEIS.

The proposed on-base (internal) roadway network hierarchy for Alternative E was determined based on the conceptual development plan and layout of the main cantonment and family housing area, and the capacity required to accommodate the expected travel demand on the facilities. The proposed on-base (internal) roadway network hierarchy diagram for Alternative E cantonment is included in Appendix F of this SEIS.

**Entry Control Facilities**

Under any of the proposed cantonment/family housing alternatives, construction of new on-base (internal) roadway facilities and entry control facilities would be required. The proposed action includes construction of on-base (internal) roadways and entry control facilities that would be implemented by the DoD. On-base (internal) roadways and entry control facilities for Alternative E, include, but are not limited to, the following:

- The existing gate would be closed and a new Finegayan Main Gate would be constructed. The new Finegayan Main Gate would form the fourth leg (eastbound approach) of the existing Route 3/Chalan Kareta intersection.
- A new Commercial/Tactical Vehicle Gate (unattended) would be constructed at the north end of the cantonment on Route 3A.
- The existing AAFB Main Gate on Route 9, and the existing Santa Rosa Gate on Route 15, would provide direct access to the family housing area. The AAFB Santa Rosa Gate would be improved as part of the proposed action.

All on-base (internal) roadway segments and intersections have been designed with the capacity required to accommodate the expected travel demand. Specifically, on-base (internal) roadway segments and intersections are designed to operate at acceptable LOS (LOS A, B, C, D, or E) under future year (Year 2030) conditions with the proposed action. Alternative E would not result in significant long-term, direct impact to on-base (internal) roadways or intersections, because Alternative E would not:

- For roadway segments and intersections - cause a roadway segment or intersection operating at acceptable LOS (LOS A, B, C, D, or E) to degrade to unacceptable LOS F.
- For roadway segments - add 5% or more to the total directional peak hour volume (measured in passenger car equivalents) and result in unacceptable LOS F.
- For intersections - add 50 or more peak hour trips (measured in passenger car equivalents) and result in unacceptable LOS F.
Transit Conditions

Implementation of Alternative E would not result in significant long-term, direct impact to transit, because Alternative E would not:

- Substantially increase traffic hazards to transit due to a design feature (e.g., sharp curves or dangerous intersections) that does not comply with applicable design standards.
- Fundamentally conflict with adopted policies, plans, or programs regarding public transit, or otherwise decrease the performance or safety of transit facilities.

Pedestrian and Bicycle Conditions

Bicycle and pedestrian facilities would be included in the construction of new on-base (internal) roadway facilities. Bicycle and pedestrian paths and facilities are integrated into the on-base transportation network as a means to improve mobility and safety of non-motorized traffic. The proposed bicycle and pedestrian network diagram for Alternative E is provided in Appendix F of this SEIS.

The proposed bicycle and pedestrian network at Finegayan includes an extensive multi-purpose trail network along most major roadways that would provide access to most facilities within the cantonment. Additionally, a jogging/biking trail would circumnavigate the periphery of the cantonment. The proposed bicycle and pedestrian network at AAFB includes a multi-purpose trail along the main corridor of the family housing area. Additionally, all residential streets would be constructed with sidewalks on both sides and a jogging/biking trail would circumnavigate the periphery of the family housing area.

Implementation of Alternative E would not result in significant long-term, direct impact to pedestrians or bicycles because Alternative E would not:

- Substantially increase traffic hazards to pedestrians or bicycles due to a design feature (e.g., sharp curves or dangerous intersections) that does not comply with applicable design standards.
- Fundamentally conflict with adopted policies, plans, or programs regarding bicycle or pedestrian facilities, or otherwise decrease the performance or safety of such facilities.

4.5.13 Marine Transportation

4.5.13.1 Affected Environment

The level of use of marine transportation facilities is predicted to be the same regardless of the selected alternative. Therefore, the affected environment for marine transportation under Alternative E is the same as described in Section 3.1.13.1 for Alternative A.

4.5.13.2 Environmental Consequences

The environmental consequences for marine transportation under Alternative E would be the same as described in Section 4.1.13.2 for Alternative A. Short-term and long-term impacts would be less than significant.

4.5.14 Utilities

4.5.14.1 Affected Environment

Electrical Power

Electrical distribution for the cantonment of Alternative E at Finegayan is the same as Alternative A. This includes the existing federally owned power distribution system solely for critical Naval Computer and Telecommunications Station operations. The general power being supplied to this area comes from the
GPA generation system via a 34.5 kV transmission line (owned by the DoD and leased to the GPA). The situation and condition of these utility systems is unchanged from the 2010 Final EIS (Volume 6, Chapter 3: Utilities, Section 3.1: Affected Environment, pages 3-5).

There is existing power infrastructure for the existing Family Housing at AAFB. The electrical power is provided by GPA 34.5 kV transmission lines along Routes 3, 9, and 1 that feed the recently replaced main substation at AAFB.

**Potable Water**

The affected environment for the potable water utility under Alternative E is the same as under Alternatives A and C.

**Wastewater**

The GWA compliance background presented in Section 4.1.14.1 for Alternative A is the same for Alternative E.

The affected environment for the cantonment at Finegayan in Alternative E is the same as Alternative A. The affected environment for the family housing in Alternative E is the same as Alternative C. Both existing DoD wastewater collection systems at Finegayan and AAFB convey flow to a GWA interceptor sewer along Route 9 and Route 3 to the Northern District WWTP for treatment and disposal.

**Solid Waste**

The affected environment for the cantonment at Finegayan in Alternative E is the same as Alternative A. The affected environment for the family housing in Alternative E is the same as Alternative C.

**Information Technology and Communications**

The existing IT/COMM utility for the cantonment at Finegayan in Alternative E is the same as Alternative A. The existing IT/COMM utility includes existing DoD and commercial telecommunication duct banks, manholes/handholes, and connection buildings. The existing DoD IT/COMM infrastructure has extensive high bandwidth fiber optic distribution systems present throughout the Finegayan site. This infrastructure includes a system of duct banks and manholes/handholes that feed from existing Building 112 on Finegayan where the existing telecommunication node is located.

Existing commercial phone and television services at Finegayan are provided through a combination of overhead and underground distribution lines from local service providers. Telephone services at the Finegayan site are currently provided by GTA TeleGuam via the existing Astumbo telephone switching station along Route 3. Television services at Finegayan are currently provided by MCV from an overhead distribution line along Route 3. The existing IT/COMM at the family housing area at AAFB in Alternative E is the same as Alternative C and includes existing and underground DoD and commercial communication lines.

4.5.14.2 Environmental Consequences

**Electrical Power**

The environmental consequences of Alternative E are the same as Alternative A. The reduction in the projected load as a result of moving the housing load to AAFB does not impact the environmental consequences as discussed in Alternative A. Also the existing AAFB main substation has adequate capacity to support the proposed new housing at AAFB.
Therefore, the environmental impact to the electrical power resource for Alternative E is less than significant for both construction and operations at both the cantonment and family housing areas.

**Potable Water**

The existing DoD water system at Finegayan does not have the additional capacity to handle the increased demand from the cantonment portion of the proposed action. The proposed potable water distribution system for the Marine Corps cantonment under Alternative E has been developed to handle the system demands of the proposed action. The current water system serving existing facilities would remain in service, with interconnections to the proposed water system to provide for redundancy and operational efficiency. There are seven active water production wells currently producing water on Finegayan and one operational well on standby being used as an aquifer monitoring well. There are also some GWA water production wells in the area along Route 3. Continued use of some of these wells would need to be negotiated with the GEPA due to the proximity of proposed cantonment facilities that are within the wellhead protection zone and could cause groundwater contamination. Through the use of best management practices and protective design features, it appears that it may be feasible to keep the DON Finegayan wells in service. Initial discussions regarding this approach have been held with GEPA on May 16, 2014. Agreement in principle on this approach has been obtained. All construction and operation activities within the wellhead protection zone of DoD wells would be done in accordance with GEPA regulations, as described above.

There would be no significant direct, short-term impact to current DoD water customers as the proposed system would supplement any lost water production. During construction, the proposed system would have excess capacity until the Marine Corps fully occupies the proposed cantonment installation. It should also be noted that the water production from the existing Finegayan wells is used to meet demands from both existing facilities and operations at Finegayan, Barrigada and other DON users as needed. It is also anticipated that the proposed water supply wells at AAFB would be installed during the early phases of construction. The short- and long-term direct impact to the Finegayan DoD potable water system from Alternative E is therefore considered less than significant during both construction and final operational conditions.

At AAFB there is an existing potable water distribution system serving the area proposed for family housing that would need to be restructured during the redevelopment proposed under Alternative E. As part of the DoD water system improvements to support the proposed action, approximately 11 new water supply wells are proposed to be installed at AAFB. This new water supply system would also be tied into the existing AAFB water system. The proposed potable water distribution system for Alternative E has been developed to handle all system demands currently in existence for areas served by the current DoD water distribution system, in addition to the increased demand from the family housing portion of the proposed action. During construction, service would be maintained to current DoD customers via construction phasing, temporary lines, or other actions. Thus, there would be no adverse impacts for the current DoD water customers aside from potentially brief water outages during construction of the expanded and modified systems. With careful planning, these potential outages would be minimized.

**DoD Potable Water System**

The short- and long-term direct impacts to the DoD potable water system with the implementation of Alternative E would be the same as under Alternative A, as described in Section 4.1.14.2. These impacts would be less than significant during both construction and during final operational conditions because the improvements would provide adequate potable water to meet current needs, and the proposed Marine Corps facilities would be in compliance with regulatory requirements.
GWA Potable Water System

Potential impacts to the GWA system would be the same for Alternative E as for Alternative A, as described in Section 4.1.14.2. Thus, the short- and long-term impact to the GWA’s distribution system from the proposed action is expected to be less than significant due to the small increase in demand from the indirect impacts of the proposed action.

NGLA Water Extraction

Potential short- and long-term impacts to the NGLA and proposed mitigation measures for impacts would be the same for Alternative E as for Alternative A, as described in Section 4.1.14.2. Thus, the localized direct impact to the NGLA is considered significant, but the impact to the overall NGLA is less than significant.

Wastewater

The proposed wastewater infrastructure for Alternative E, as described in Section 2.4.4.5, has been developed to meet the needs of the proposed action. As described below, the potential impacts and mitigations for wastewater utilities for Alternative E would be the same as for Alternative A.

In 2010, the DON conducted a sewer capacity study (DON 2010) using a hydraulic model developed for the GWA WRMP that was modified and calibrated with 2010 flow monitoring data. Based on the flow scenario in the sewer capacity study (which was similar to the 2010 Final EIS proposed action estimated flows), the GWA interceptor sewer along Route 3 and Route 9 can adequately convey dry- and wet-weather flows. The GWA interceptor sewer ranges in size from 30 inches (76 cm) to 42 inches (107 cm) in diameter along Routes 3 and 9. There is one segment of each sewer size where the maximum flow depth could be three quarters of the pipe diameter at peak flows. Updated sewer collection system model runs were completed and the results show that the existing sewers have adequate capacity to handle the projected flow in year 2028. However, in late 2014 the DON obtained closed circuit television footage from GWA of the main sewer lines from AAFB to the Northern District WWTP, mostly routed along Routes 3 and 9. Based on available information from closed-circuit television footage of the Northern District WWTP collection system, the concrete reinforced pipe sewer line from AAFB to the Northern District WWTP along Routes 3 and 9 is in a state of deteriorated condition that requires rehabilitation or replacement. Therefore, this operations impact is significant but mitigable.

GovGuam received funding from USEPA to conduct the sewer system evaluation survey in northern Guam. GWA awarded a sewer system evaluation survey of the northern collection system in late 2014, but those results were not available at the time of publication of the Final SEIS.

The Northern District WWTP currently treats wastewater to primary treatment standards. The 2013 NPDES permit for the plant requires discharge to meet secondary treatment standards and Guam Water Quality Standards, including those for nutrients. The Northern District WWTP requires treatment system upgrades to meet the NPDES permit standards. Until the required upgrades are operational, additional projected wastewater flows from the proposed action and all other sources would be treated to primary treatment standards. Increasing the wastewater flow to a non-compliant treatment plant would be a significant direct impact during the period of non-compliance with the permit. Because some of the proposed construction would occur during this period of non-compliance, there would be direct and unmitigable significant impacts to the wastewater system until the Northern District WWTP upgrades are completed.
Upgrading the Northern District WWTP treatment systems (as required by the 2013 NPDES permit) would mitigate significant impacts to the wastewater system on Guam. The FY 2014 NDAA directed the Secretary of Defense to convene the EAC in part to develop an implementation plan that will address public infrastructure requirements necessary to support the preferred alternative. The implementation plan will detail descriptions of work, costs, and schedules for completion of construction, improvements, and repairs to Guam public infrastructure affected by the realignment, including improvements and upgrades to the Guam wastewater system. The water and wastewater assessment that DoD prepared to support the implementation plan recommends upgrades to the Northern District WWTP and refurbishment of the GWA interceptor sewer from AAFB to the Northern District WWTP. Section 8102 of the FY 2014 Consolidated Appropriations Act (Public Law No. 113-76) appropriated $106.4 million to the Secretary of Defense, acting through the OEA, for civilian water and wastewater improvements on Guam. These funds will remain available until expended.

The indirect impacts to the Agaña WWTP from Alternative E are the same as from Alternative A, as described in Section 4.1.14.2. Under Alternative E, the increased wastewater flows from the proposed action would be considered negligible (less than 1% of the total projected flow [see Table 4.1.14-2]). Therefore, consistent with impact assessment criteria in the SEIS, the impact from the proposed action to Agaña WWTP would be less than significant.

The indirect impacts to the central wastewater collection system conveying flow to the Agaña WWTP are deemed less than significant due to the negligible increase in flow from the proposed action for both construction and operations.

The indirect impacts to GWA’s southern WWTPs and collection systems from Alternative E are the same as from Alternative A, as described in Section 4.1.14.2. With the negligible flows anticipated to these southern wastewater systems and the planned capital improvements projects, the indirect impacts of the proposed action would be less than significant, for both construction and operations.

Mitigation measures for significant impacts in Alternative E would be the same as in Alternative A as described in Section 4.1.14.2.

Solid Waste

The environmental consequences for the solid waste infrastructure associated with the cantonment at Finegayan are similar to Alternative A. The differences with Alternative A are that the family housing area would be located at AAFB and not Finegayan and would also require increased C&D waste generation from the additional housing units being demolished and constructed. The handling of this additional C&D waste would be the same as for Alternative A. The family housing area located at AAFB would be served by the existing local solid waste infrastructure at AAFB that currently services the existing family housing area. The impacts to the existing solid waste infrastructure would be an approximate 11% increase to the solid waste generation based on the increased number of housing units planned for the AAFB family housing area. The environmental consequences to the solid waste infrastructure serving the AAFB family housing area would be the same as described for Alternative C.

Therefore, the potential long-term direct impact on the Guam solid waste infrastructure support systems for Alternative E would be less than significant.

Information Technology and Communications

As in Alternative A, the current DoD IT/COMM infrastructure for the cantonment at Finegayan in Alternative E would remain in place during and after the proposed new facilities are constructed and in operation. Any existing lines for areas that would be under new roads, parking lots, or other areas subject to loads at ground surface would have to be encased in concrete, and several existing communication
lines would require rerouting. During this rerouting construction, close coordination with Naval Computer and Telecommunications Station operations would be required to ensure any critical communication lines impacted would be kept in operation via alternate signal routing. Existing Building 112 currently has adequate connection capacity to handle additional IT/COMM connectivity that would be required by the proposed alternative at Finegayan, but additional distribution of conduit and lines would need to be installed to properly interconnect the DoD communications requirements. New duct banks required for Alternative A as described in Chapter 2 of this SEIS include a duct bank of up to twelve 4-inch (10-cm) conduits looped between the main IT/COMM distribution facilities, as well as a system of duct banks and various conduits distributed in and around the site connecting the main distribution facilities to each building or end user. Various cables types would be required within this system of conduits, including 144 and 288 strand fiber optic cables, copper cables with 600 pair telephone lines, and smaller cables to individual buildings.

Additional inter-base IT/COMM connectivity would be required as described in Chapter 2. This includes the connection between AAFB and the existing Tata cable landing facility in southern Guam, which would require new rights of way along some southern roads and the access road to the Tata facility.

Current DoD IT/COMM underground communication lines within the family housing area at AAFB would remain in place during and after the proposed new facilities are constructed and in operation. Any existing lines for areas that would be under new roads, parking lots, or other areas subject to loads at ground surface would have to be encased in concrete, and several existing communication lines would require rerouting. During this rerouting construction, close coordination with the Department of the Air Force operations would be required to ensure any critical communication lines impacted would be kept in operation via alternate signal routing.

The current commercial IT/COMM facilities have adequate capacity within nearby infrastructure at Finegayan for the cantonment and at AAFB for the family housing. The existing commercial cables within the proposed remodeled family housing area at AAFB could be rerouted or demolished as required. New duct banks would be required to provide commercial service to the proposed cantonment area at Finegayan and the family housing at AAFB. There could be short-term lack of commercial service during the construction phase, but no permanent or long-term environmental consequences to the commercial IT/COMM infrastructure. The direct impact to IT/COMM is deemed less than significant both during construction and in operation.

4.5.15 Socioeconomics and General Services

4.5.15.1 Affected Environment

The affected environment for socioeconomics and general services on Guam is presented for the entire island of Guam and does not vary by alternative. Because the affected environment does not vary by alternative, it is only presented one time, under Alternative A. A full description of the affected environment for socioeconomic and general services is presented in Section 4.1.15.

4.5.15.2 Environmental Consequences

The socioeconomics and general services impacts under Alternative E would be island-wide, direct and indirect, short- and long-term, and would be the same as described under Alternative A in Section 4.1.15. The population change associated with Alternative E would not likely put excessive strain on Guam’s public services and permitting agencies, and the estimated increases in GovGuam tax revenues would likely compensate for any increased demand that would occur. The economic impacts would be beneficial, leading to increased employment and standards of living, and impacts to Guam’s housing
stock and availability would not bring about reactionary development, which could have otherwise lead to dislocations in the housing market. There is a potential for sociocultural impacts to occur, but the magnitude of the impacts could vary substantially based on policy and program choices yet to be made on how to address them.

**4.5.16 Hazardous Materials and Waste**

**4.5.16.1 Affected Environment**

Under Alternative E, the affected environment for hazardous materials and waste is as described for Alternative A (Section 4.1.16.1) and Alternative C (Section 4.3.16.1). The affected environment for hazardous materials and waste management is summarized briefly below under the following two subheadings: Finegayan (cantonment), and AAFB (housing).

**Finegayan (Cantonment)**

NAVFAC is responsible for overseeing the management of hazardous materials on all DON facilities on Guam. Hazardous materials at Naval Base Guam are stored at a warehouse operated by Joint Environmental Material Management Service. Joint Environmental Material Management Service consolidates hazardous materials for reuse and tracks it through an inventory management program. Unused hazardous materials are returned to Joint Environmental Material Management Service for redistribution or disposal.

Operations at DoD installations on Guam generate a variety of hazardous waste, including, but not limited to waste of: medical and dental supplies, adhesives, solvents, contaminated absorbents, corrosive liquids, aerosols, pesticides, used POLs, and sludges. In accordance with DoD policies, all facilities must seek to reduce or eliminate hazardous waste generation by implementing BMPs, SOPs, and best available technologies. DRMO maintains all hazardous waste documentation and ensures that all disposal actions are performed in accordance with pertinent federal, state, and local laws and regulations.

There are two IRP sites located on Finegayan; however, these sites are not located within the proposed footprint of the main cantonment. The sites are summarized in Table 4.1.16-1 and depicted in Figure 4.1.16-1.

**AAFB (Housing)**

Hazardous materials at AAFB are managed by the installation’s Hazardous Materials Pharmacy, under the Logistics Readiness Squadron. The Air Force has requirements for readily accessible fuel and related storage facilities on Guam. Numerous fueling operations to support aircraft, vehicle operation, and emergency power generation are performed at AAFB. The majority of fuel is aviation fuel.

DRMO arranges for all hazardous waste collection, transportation, and disposal via licensed contractors who ultimately dispose of the hazardous waste at permitted off-island disposal facilities (AAFB 2007).

There are six IRP and potentially contaminated sites located in the AAFB ROI (see Table 4.3.16-1), however, only 1 is located within the proposed family housing footprint. The remaining sites are at such a distance from the proposed family housing footprint that they are unlikely to affect site conditions. Additionally, the majority of the sites have been remediated or determined to not present a risk to human health or ecological receptors. Those sites that are currently active or have land use restrictions are depicted in Figure 4.3.16-1.
4.5.16.2 Environmental Consequences

Short-term construction impacts and long-term operational impacts to hazardous materials and waste under Alternative E would be similar to those described under Alternative A (Section 4.1.16.2) and Alternative C (Section 4.3.16.2) of this SEIS.

In summary, adherence to applicable BMPs and SOPs during construction and operations would reduce the likelihood and volume of accidental releases, allow for accelerated spill response times and enable timely implementation of cleanup measures, thereby minimizing potential impacts to the environment. Construction and demolition activities associated with this alternative would have no long-term direct or indirect impact on the management of hazardous materials at DoD facilities on Guam. Hazardous materials would continue to be managed under established hazardous material SOPs. Indirect Long-term beneficial impacts would occur to fuel storage and conveyance infrastructure as it would need to be brought into compliance before planned increases in capacity could be implemented.

The overall reduction in long-term increased use of hazardous materials from operations under the SEIS alternatives, as compared to the 2010 Final EIS, would be dependent on a variety of factors and cannot be quantified based on available information. Although reduced relative to the 2010 Final EIS volumes of hazardous materials, operations under Alternative E would still represent a substantial long-term increase in the volumes of hazardous materials relative to baseline conditions.

Should suspected environmental contamination be encountered during construction or operational activities, work would stop and the appropriate authorities would be notified. If appropriate, soil and groundwater samples would be collected to determine the nature and the extent of the contamination and whether remedial action would be required.

Under Alternative E, direct or indirect impacts to contaminated sites from construction or operations would be less than significant. Any potentially contaminated sites would be assessed and remediated, as appropriate, for the proposed reuse of the site. Construction or operational activities would not disturb any remediation sites or controls or interfere with monitoring areas, if present.

Should there be a need to import off-island earthen materials, all GEPA, Department of Agriculture, and local rules and regulations would be followed.

Therefore, implementation of Alternative E would result in less than significant direct and indirect impacts to hazardous materials and waste.

4.5.17 Public Health and Safety

4.5.17.1 Affected Environment

Under Alternative E, the affected environment for public health and safety is as described for Alternative A and Alternative C in Section 4.1.17.1 and Section 4.3.17.1, respectively. In addition, an extensive discussion of the affected environment for public health and safety matters on Guam is provided in the 2010 Final EIS (Volume 2, Chapter 18: Public Health and Safety, Section 18.1: Affected Environment, pages 18-1 to 18-12).

In summary, to protect the general public from intentional or accidental entry onto Finegayan or AAFB, locked or manned gates are used where vehicle access is provided and a series of signs warning unauthorized personnel not to enter the area are posted along the perimeter of the installation. Unauthorized personnel are not allowed on the installation at any time.
Activities on existing small arms range at both Finegayan and AAFB are conducted in accordance with SOPs to ensure the safety of both range participants as well as the public. While these existing small arms ranges are not part of the proposed action, they would remain active at both locations. Additionally, the areas proposed for housing at AAFB under Alternative E are situated outside of the APZs. Off-base lands within the APZ were addressed in the 2010 Final EIS (Volume 2, Chapter 8: Land and Submerged Land Use, Section 8.1.2.1: Andersen AFB, page 8-24).

Aircraft take-off/departure from AAFB flies over Finegayan, generating noise in the range of 60-65 dBA. Current noise levels are within the acceptable range for cantonment/residential facilities. At AAFB, the areas proposed for housing that are south of the airfield are situated within the 60-70 dB noise contours. Areas north and west of the airfield are within the 65-80 dB noise contours (see Figure 4.1.4-1). Details regarding current noise conditions at AAFB are provided in Section 4.3.4.1.

4.5.17.2 Environmental Consequences

Potential direct and indirect impacts on public health and safety from implementation of Alternative E would be similar to those discussed under Alternative A (Section 4.1.17.2) and Alternative C (Section 4.3.17.2).

Notifiable Diseases

Potential increases in notifiable diseases for Alternative E would be the same as discussed in Section 4.1.17.2 for Alternative A.

Mental Illness

Potential increases in mental illness for Alternative E would be the same as discussed in Section 4.1.17.2 for Alternative A.

Operational Safety

To protect the general public from intentional or accidental entry onto Finegayan and AAFB, locked or manned gates would continue to be used where vehicle access is provided and a series of signs warning unauthorized personnel not to enter the area would remain posted along the perimeter of the installation. Unauthorized personnel would not be allowed on the installation at any time.

The areas proposed for housing at AAFB are situated outside of the APZs. Specific and documented procedures would be in place to ensure the public is not endangered by operations and training activities. Therefore, Alternative E would result in no direct or indirect impacts on public health and safety (resulting from operations and training activities).

Construction and infrastructure improvements related to the proposed military relocation to Finegayan and AAFB would be consistent with established ESQD areas on the installations. SOPs would ensure the safe transportation of munitions, and incident response procedures are in place in the event of a munitions transport incident.

In addition, no direct or indirect impact on public health and safety related to electromagnetic emissions is anticipated.

Because a health and safety program would be implemented for construction activities and the public would be excluded from entering construction areas, potential short-term construction impacts on public health and safety would not result in any greater safety risk.

Therefore, no significant impacts associated with operational safety would occur.
Environmental Health Effects

Potential short-term construction and long-term operational noise emissions associated with Alternative E would be similar to those discussed under Alternative A and Alternative C. Enforcement of OSHA guidelines for hearing protection for workers would be the responsibility of the construction contractor. The public would be excluded from entering construction areas. Therefore, short-term construction noise impacts on public health and safety would be less than significant. Long-term operational noise from activities occurring on Finegayan and AAFB would be similar to current noise levels. The area proposed for housing that is south of the airfield is situated within the 60 to 70 dB noise range and is compatible with residential development. Areas north and west of the airfield are within the 65 to 80 dB noise range. These areas would mostly be incompatible for residential development but would allow for operations activities. Construction of buildings in these areas should implement noise level reduction measures to reduce interior noise levels to allow normal conversation. Existing aircraft noise is not at a level that would result in the loss of hearing of housing area occupants. Therefore, the overall direct or indirect impacts associated with noise to human health and safety would be less than significant.

Potential water quality impacts associated with Alternative E would be similar to those discussed under Alternative A and Alternative C. Groundwater withdrawal would likely increase. However, sustainability practices would be implemented to reduce the amount of groundwater needed. Proposed development and operational activities would be conducted in accordance with GEPA guidance and BMPs to minimize the potential for contaminants to be introduced in these areas. Therefore, direct and indirect public health and safety impacts from long-term increased demand on potable water and potential water-related illnesses would be less than significant.

Hazardous Substances

Potential direct impacts from hazardous substances for Alternative E would be similar to those discussed under Alternative A and Alternative C. The use, handling, storage, transportation, and disposition of hazardous substances would be conducted in accordance with applicable hazardous material and waste regulations, and established BMPs and SOPs to ensure that the health and safety of workers and the general public is maintained.

IRP investigations and/or remediation activities, as necessary, would continue in an effort to clean up past releases of hazardous substances and receive regulator concurrence that necessary actions have been completed to ensure the safety of the public. No off-site population is near the IRP sites. Building construction is not proposed within the footprint of IRP sites. Based on investigations of the contaminants associated with sites on Finegayan and AAFB (within proposed cantonment and housing development areas), no health hazards have been identified. Because hazardous substance management and IRP investigative/cleanup activities would be conducted in accordance with applicable regulations and established BMPs and SOPs, no direct or indirect impacts on public health and safety are anticipated.

Unexploded Ordnance

Potential direct impacts from UXO under Alternative E would be similar to those discussed under Alternative A and Alternative C. The general public would be excluded from entering construction zones and training areas. BMPs would be implemented to identify and remove potential MEC items prior to the initiation of ground-disturbing activities. UXO personnel supervision would occur during earth-moving activities and MEC awareness training would be provided to construction personnel involved in grading and excavations prior to and during ground-disturbing activities. Because UXO would be identified and removed prior to initiating construction activities and construction personnel would be trained as to the
hazards associated with UXO, potential direct impacts from encounters with UXO would be minimized and less than significant.

**Traffic Incidents**

As a result of the long-term increase in military personnel and their dependents, there would be more vehicles on the roadways potentially resulting in more heavily congested roadways and, thus, more potential for accidents and traffic fatalities. As illustrated in Table 4.1.17-4, the annual number of traffic accidents could increase. Although implementing Alternative E could mean more military personnel on the roads, the actual potential for increased traffic incidents is small (5% increase/358 traffic incidents annually). Because no high crash frequency intersections are located near Finegayan or AAFB and the overall long-term potential increase in the number of traffic accidents as a result of the increase in personnel would be minimal, there would be a less than significant impact on the health and safety of the citizens of Guam (from traffic incidents).

**4.5.18 Environmental Justice and the Protection of Children**

4.5.18.1 Affected Environment

As described in Alternative A, the affected environment for environmental justice and the protection of children analysis is the entire island of Guam. Therefore, the affected environment for Alternative E is the same as for Alternative A. In addition, both Alternative E locations are in the northern area of the island, the same region as Alternative A. The villages of Dededo and Yigo are within this region.

4.5.18.2 Environmental Consequences

Potential impacts to environmental justice populations under Alternative E would be to noise, recreation, socioeconomic and general services (including health services), and public health and safety.

**Noise**

The potential impacts would be the same as Alternative A.

**Recreation**

Impacts are generally island-wide and would be the same as described for Alternative A.

**Socioeconomics and General Services**

Impacts are generally island-wide and would be the same as described for Alternative A, as would the identified measures to mitigate impacts.

**Public Health and Safety**

Impacts are generally island-wide and would be the same as described for Alternative A, as would the identified measures to mitigate impacts.
4.6 **NO-ACTION ALTERNATIVE FOR CANTONMENT/HOUSING**

Under the No-Action Alternative for this SEIS, the DON would continue to implement the September 2010 ROD, including construction and operation of a cantonment area for approximately 8,600 Marines and approximately 9,000 dependents on DoD-controlled lands at Finegayan and South Finegayan and by acquiring land known as the former FAA parcel.

4.6.1 **Geological and Soil Resources**

For the No-Action Alternative, the impacts to geological and soil resources would be the same as those described for the preferred alternative (Alternative 2) in the 2010 Final EIS (Volume 2, Chapter 3: Geological and Soil Resources, Section 3.2.3, page 3-49). Under the No-Action Alternative, there would be adverse, but less than significant, direct long-term impacts to topography due to permanent alteration of the landscape. The construction footprint for the No-Action Alternative would be 78% larger than the footprint for Alternative A and would involve a proportionately larger amount of excavation than Alternative A. Approximately 62 features have been preliminarily identified as sinkholes or depressions that may contain sinkholes within or on the perimeter of the No-Action Alternative footprint but there would be less than significant direct, short- and long-term impacts to sinkholes with implementation of sinkhole protection measures. By comparison, 43 similar features have been identified for Alternative A (the most for any of the action alternatives) which would also have less than significant direct, short- and long-term impacts to sinkholes with implementation of sinkhole protection measures.

4.6.2 **Water Resources**

For the No-Action Alternative, impacts to water resources would be generally as described for the preferred alternative (Alternative 2) in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.3: Alternative 2 (Preferred Alternative), pages 4-118 to 4-123), except as updated below with new information or analysis.

No buildings/structures would be constructed in the 100-year or 500-year flood zones and no surface waters are located within or near the proposed construction areas under the No-Action Alternative. Given compliance with the Construction General Permit and BMPs, off-site transport of stormwater runoff, sediment, or other pollutants would be unlikely. Therefore, construction activities associated with the No-Action Alternative would result in no impacts to surface waters.

While it is expected that the GWA could meet the increased potable water demand during construction and that there would only be a minimal increase in pumping from the NGLA due to construction, the number of spills from GWA’s sewage collection system continues to greatly exceed spill rate norms for similar wastewater systems. Increased wastewater flows associated with the additional construction/DoD workforce would potentially increase the rate of sewage spills, potentially resulting in significant indirect impacts to groundwater quality during construction.

The No-Action Alternative would add substantially more impervious surface area to Guam (883 acres [357 ha]), as compared to the action alternatives discussed in Chapter 4, with Alternative D having the greatest increase in impervious area (319 acres [129 ha]) of the five action alternatives.

After construction, the large increase in island-wide demand on the existing Guam sewer collection systems, due to the large amount of induced growth projected (as compared to the five SEIS action alternatives), would result in significant adverse indirect impacts from increased potential for sewage spills anywhere on the central sewer collection system. Such spills could affect all categories of water resources (e.g., surface waters, groundwater, nearshore waters) anywhere on Guam. These impacts would
be mitigated by improvements and upgrades to the Guam wastewater system and expansion/rehabilitation of the NGLA monitoring well network, as described for the wastewater impacts of the SEIS action alternatives (see Section 4.1.2.2).

The No-Action Alternative and the five action alternatives would have similar short-term significant direct impacts to nearshore waters. Upgrades of the Agaña WWTP and Northern District WWTP treatment systems in the long-term would be beneficial to the water quality of nearshore waters. However, until the WWTP upgrades were completed there would be an indirect and unmitigable significant impact to nearshore waters during construction and operation. The No-Action Alternative would have no direct impacts on wetlands similar to Alternatives A, B, C, and E.

Under the No-Action Alternative the estimated daily average groundwater withdrawals from the NGLA to meet potable water demand would be 5.8 MGd (22.0 MLD), as compared to 1.7 MGd (6.4 MLD) for the five action alternatives in this SEIS. The 2010 Final EIS concluded that groundwater withdrawals from the NGLA would result in less than significant impacts. However, results from the new USGS study, which was completed in 2013 (USGS 2013c), indicate that the five action alternatives would result in localized significant impacts to the NGLA, and less than significant impacts to the overall NGLA. Therefore, it is assumed that the significantly larger groundwater withdrawals under the No-Action Alternative would have similar, but greater localized significant impacts to the NGLA that would be mitigated as described for the action alternatives.

4.6.3  Air Quality

For the No-Action Alternative, air quality impacts would be the same as those described for the preferred alternative (Alternative 2) in the 2010 Final EIS (Volume 2, Chapter 5: Air Quality, Section 5.2.3: Preferred Alternative (Alternative 2), pages 5-27 to 5-29 and 5-35 and Volume 6, Chapter 7: pages 7-37 to 7-46 and 7-72). Air quality impacts under the No-Action Alternative and the action alternatives discussed in Chapter 4 would be less than significant. However, impacts under the No-Action Alternative would be slightly greater than the action alternatives, given the greater scale of construction and operational activities.

4.6.4  Noise

Under the No-Action Alternative, noise impacts would be the same as those described for the preferred alternative (Alternative 2) in the 2010 Final EIS (Volume 2, Chapter 6: Noise, Section 6.2.3: Preferred Alternative (Alternative 2), pages 6-21 to 6-59 and Volume 6, Chapter 8: Noise, Section 8.2: Environmental Consequences, pages 8-11 to 8-50). Noise impacts under the No-Action Alternative would be less than significant or significant but mitigable, depending on the location of construction activities. By comparison, the construction period for the action alternatives discussed in Chapter 4 would be extended, which would allow for the construction schedule to sequence work tasks and only one or two pieces of heavy equipment to operate in areas close to the nearest receptors, resulting in a reduction of noise impacts. As a result, all of the action alternatives would result in less than significant noise impacts with the implementation of BMPs.

4.6.5  Airspace

For the No-Action Alternative, impacts to airspace would be the same as those described for the preferred alternative (Alternative 2) in the 2010 Final EIS (Volume 2, Chapter 7: Airspace, Section 7.2.3: Alternative 2 (Preferred Alternative), page 7-15). There would be no impacts to airspace for both the No-Action Alternative and action alternatives discussed in Chapter 4.
4.6.6 Land and Submerged Land Use

For the No-Action Alternative, impacts to land and submerged land use would be the same as those described for the preferred alternative (Alternative 2) in the 2010 Final EIS (Volume 2, Chapter 8: Land and Submerged Land Use, Section 8.2.4: Alternative 2 (Preferred Alternative), pages 8-75 to 8-76). The No-Action Alternative would be developed on federally owned land (Finegayan and South Finegayan) but would also require land acquisition of the former FAA parcel (680 acres [275 ha]). By comparison, the action alternatives discussed in Chapter 4 would not require land acquisition. Significant but mitigable impacts to land use under the No-Action Alternative would result from the new public access restrictions to the Latte Stone Park at South Finegayan. To mitigate this impact to a less than significant level, the DoD would work with the community to provide access to Latte Stone Park to the extent practicable. Similar significant impacts under the proposed action (2012 Roadmap Adjustments) would only occur under Alternative B due to similar public access restrictions to the Latte Stone Park. Additional significant public access impacts would occur under the No-Action Alternative due to loss of public access to the jogging trail at the former FAA parcel but this impact would be unmitigable.

4.6.7 Recreational Resources

For the No-Action Alternative, impacts to recreational resources would be the same as those described for the preferred alternative (Alternative 2) in the 2010 Final EIS (Volume 2, Chapter 9: Recreational Resources, Section 9.2.3: Alternative 2 (Preferred Alternative), pages 9-27 to 9-29). There would be significant impacts to recreational resources (i.e., increased user demand, accelerated deterioration, diminished user satisfaction due to reduced recreational opportunities, and conflicts between users and uses) under the No-Action Alternative, while there would be would less than significant impacts to recreational resources under the action alternatives discussed in Chapter 4 due to the substantially smaller number of Marines and dependents that would arrive on Guam.

4.6.8 Terrestrial Biological Resources

Table 4.6.8-1 provides a brief summary of terrestrial biological resource impacts that would result with implementation of the No-Action Alternative as described in the 2010 ROD and as the preferred alternative in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.3: Alternative 2, pages 10-169 to 10-177).

Table 4.6.8-1. Potential Impacts from the Proposed Cantonment/Family Housing Area under the No-Action Alternative

<table>
<thead>
<tr>
<th>Impact Component</th>
<th>Vegetation</th>
<th>Special Management Areas</th>
<th>Wildlife</th>
<th>SS Species (significant impacts only)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cantonment/Family Housing at Finegayan, South Finegayan, and the Former FAA Parcel</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Construction</td>
<td>Direct - SI</td>
<td>Direct - SI (Loss of 1,106 acres (448 ha) of Overlay Refuge)</td>
<td>Direct - LSI Indirect - LSI</td>
<td>ESA-Listed Fruit Bat: Direct - SI-M (loss of habitat) Indirect - SI-M (invasive species) All other SS species currently present: Indirect - SI-M (invasive species)</td>
</tr>
</tbody>
</table>

Legend: LSI = less than significant impact, SI = significant impact, and SI-M = significant impact that is mitigable.
Of the approximate 21,690 acres (8,778 ha) of Overlay Refuge, 1,106 acres (448 ha) would be removed with construction of the cantonment area as proposed under the preferred alternative in the 2010 ROD. This area represents 5.1% of Overlay Refuge lands on Guam. Overlay Refuge lands contain habitat that would be suitable for recovery efforts of special-status species, including those that do not presently occur within the action area.

The 2010 Final EIS concluded that implementation of the preferred alternative would result in significant impacts to the Mariana crow and Guam Micronesian kingfisher. However, the Mariana crow is now considered extirpated from Guam (Personal communication via letter from USFWS, Pacific Islands Fish and Wildlife Office, Honolulu, HI regarding the DON NOI for Proposed Placement of LFTRC on Guam NWR, December 7, 2012). As both the crow and the kingfisher are extirpated from Guam, there would be no impacts to these species from the construction and operation of the proposed cantonment/family housing complex under the No-Action Alternative.

There would be a direct, significant impact on the Mariana fruit bat due to the removal of 816 acres (330 ha) of suitable habitat during construction and indirectly due to disturbance of habitat adjacent to the proposed facilities. This would be mitigated with the conservation actions proposed in the 2010 Final EIS to less than significant.

Indirectly, movement of construction personnel, equipment, and supplies could result in the spread of invasive plant and animal species to Guam, within Guam, or to other locations from Guam. Invasive species could affect special-status species or degrade habitat and therefore would result in potential indirect impacts. Although impacts to special-status species would be significant under the No-Action Alternative, implementation of mitigation and conservation measures, such as the preparation of the Micronesia Biosecurity Plan and Hazard Analysis and Critical Control Points planning will reduce the potential impacts from invasive species to less than significant. Even though the potential impacts under the No-Action Alternative would be less than significant, those impacts would be relatively greater than those identified in the materially smaller current proposed action.

### 4.6.9 Marine Biological Resources

For the No-Action Alternative, the impacts to marine biological resources would be the same as those described for Alternative 2 in the 2010 Final EIS (Volume 2, Chapter 11: Marine Biological Resources, Section 11.2.7: Summary of Impacts, page 118 and Section 11.2.8: Summary of Essential Fish Habitat Assessment, pages 11-123 to 11-124). While less than significant impacts to marine biological resources would occur for both the No-Action Alternative and the action alternatives discussed in Chapter 4, impacts under the No-Action Alternative would be of greater intensity than those for the proposed action in this SEIS due to the larger proposed footprint and number of the Marines and dependents that would arrive on Guam.

### 4.6.10 Cultural Resources

For the No-Action Alternative, impacts to cultural resources would be the same as those described for the preferred alternative (Alternative 2) in the 2010 Final EIS (Volume 2, Chapter 12: Cultural Resources, Section 12.2.3: Preferred Alternative (Alternative 2), pages 12-57 to 12-62). The No-Action Alternative would adversely affect 12 historic properties, while the action alternatives discussed in Chapter 4 would adversely affect historic properties as follows:

- Alternative A: 21 historic properties. Seven unevaluated buildings could also be affected.
- Alternative B: 18 historic properties. Seven unevaluated building could also be affected.
- Alternative C: 17 historic properties. Twelve unevaluated buildings could also be affected.
- Alternative D: 10 historic properties. Thirteen unevaluated archaeological locations, and 8 unevaluated buildings could also be affected.
- Alternative E: 17 historic properties. Fourteen unevaluated buildings could also be affected.

The historic properties affected under the No-Action Alternative do not include utility-related construction such as the well development area, which is analyzed under the current proposed action and would affect an additional 10 historic properties and 6 unevaluated structures. The No-Action Alternative and the five action alternatives also have the potential to result in significant long-term, direct impacts to culturally important resources that are not historic properties. These significant impacts would be mitigated through measures identified in the 2011 PA, regardless of which alternative was selected for implementation. In addition, the substantially greater number of Marines and their dependents under the No-Action Alternative, as compared to the proposed action in this SEIS, would potentially result in increased accidental or inadvertent damage to historic properties, especially Latte Stone Park (GHPI Number 66-08-0141). The resulting significant long-term, direct impacts to cultural resources would be mitigated through the 2011 PA stipulation on Cultural Resources Awareness orientation.

4.6.11 Visual Resources

For the No-Action Alternative, impacts for visual resources would be the same as those described for the preferred alternative (Alternative 2) in the 2010 Final EIS (Volume 2, Chapter 13: Visual Resources, Section 13.2.3: Preferred Alternative (Alternative 2), pages 13-69 to 13-72). There would be significant impacts to visual resources under the No-Action Alternative that may be reduced to less than significant through the implementation of potential mitigation measures. By comparison, there would be less than significant impacts on visual resources under the action alternatives discussed in Chapter 4, as a result of less development associated with the reduced number of Marines and dependents that would arrive on Guam.

4.6.12 Ground Transportation

For the No-Action Alternative, impacts to ground transportation would be the same as those described for the preferred alternative (Alternative 2) in the 2010 Final EIS (Volume 6, Chapter 4: Roadways, Section 4.2.2.2: Preferred Alternative (Alternative 2), pages 4-88 to 4-89). Impacts to ground transportation may become less than significant through the implementation of potential mitigation measures, specifically, the required roadway improvements. By comparison, action alternatives would also result in less than significant impacts to ground transportation.

4.6.13 Marine Transportation

For the No-Action Alternative, impacts to marine transportation would be the same as those described for the preferred alternative (Alternative 2) in the 2010 Final EIS (Volume 2, Chapter 14: Marine Transport, Section 14.2.2.3: Apra Harbor, pages 14-11 to 14-14), but altered only by the start date of construction. The predicted level of use under the No-Action Alternative would be well below capacity of existing marine transportation resources, resulting in less than significant impacts. By comparison, the action alternatives discussed in Chapter 4 would result in a smaller increase in use due to the reduced magnitude of the proposed action.
4.6.14 Utilities

Electrical Power

For the No-Action Alternative, impacts to electrical power would be the same as described in the 2010 Final EIS (Volume 6, Chapter 3: Utilities, Section 3.2.2: Power, pages 3-47 to 3-51). Less than significant impacts to power would occur for both the No-Action Alternative and the action alternatives discussed in Chapter 4. However, upgrades to off-base electrical transmission and generation systems would be required to support the No-Action Alternative, while no upgrades to existing generating facilities would be required as a result of implementing the proposed action alternatives; and the total estimated increase in electrical demand would be three times greater under the No-Action Alternative.

Potable Water

For the No-Action Alternative, impacts for potable water would be similar to those described in the 2010 Final EIS (Volume 6, Chapter 3: Utilities, Section 3.2.3: Potable Water, pages 3-51 to 3-67). However, since the 2010 Final EIS was issued, there have been several improvement projects (completed, in-progress, or planned) for the Air Force water system. These improvements include refurbishing the Tumon-Maui well and five Marbo wells, slip lining some of the water mains to reduce leaks, and repairs to the Mount Santa Rosa Water Storage Tank to eliminate leaks. These initiatives have reportedly reduced water demand through leak elimination. The refurbished wells improve the reliability of the water supply with the Marbo wells by adding an estimated 0.23 MGd (0.87 MLd), and the Tumon-Maui well by adding up to 1.3 MGd (4.9 MLd) to the water supply when put in service. In addition, five new wells, in progress during the 2010 Final EIS preparation, have been completed at AAFB and are now in production. The 2010 Final EIS assessment included the five new planned wells at AAFB in the impacts analysis, but not the other improvements. Those other improvements should reduce the impact of the No-Action Alternative from what was in the 2010 Final EIS for the DoD water system.

The GWA water system remains much the same as presented in the 2010 Final EIS. There have been some improvements made, mostly in leak detection and repair, well maintenance, and the installation of several new wells. The general water system, however, remains similar to that analyzed in the 2010 Final EIS. The DoD system reportedly would have increased excess water production capability, and could therefore offer excess water to the GWA should the need arise. The No-Action Alternative indirect impacts to the GWA water system would be the same as presented in the 2010 Final EIS for all subcategories (supply, transmission, and distribution).

Since completion of the 2010 Final EIS, the NGLA has been the subject of a major study by the USGS with support from WERI and others. Under the No-Action Alternative the estimated daily average groundwater withdrawals from the NGLA to meet potable water demand would be 5.8 MGd (22.0 MLd), as compared to 1.7 MGd (6.4 MLd) for the five action alternatives. The 2010 Final EIS concluded that groundwater withdrawals from the NGLA would result in less than significant impacts. However, results from the new USGS study, which was completed in 2013 (USGS 2013a), indicate that the five action alternatives would result in localized significant impacts to the NGLA but would be a less than significant impact to the NGLA overall. Therefore, it is assumed that the greater groundwater withdrawals under the No-Action Alternative would have similar, but greater localized significant impacts to the NGLA that would be mitigated as described for the action alternatives. The ramifications of this new information on the No-Action Alternative would be that the impacts assessment contained in the 2010 Final EIS would be similar but that the potable water solution would likely require an increased number of new wells above that proposed for the preferred alternative.
Wastewater

For the No-Action Alternative, impacts to wastewater would be similar to those described in the 2010 Final EIS (Volume 6, Chapter 3: Utilities, Section 3.2.4: Wastewater, pages 3-69 to 3-81), with the additional significant but mitigable impact to the collection system from AAFB to the Northern District WWTP. There have been some improvements in the operation of the Northern District WWTP since the 2010 Final EIS assessment was prepared. In 2013, the primary treatment system at the Northern District WWTP was repaired and upgraded in accordance with a 2011 Court Order. A capacity evaluation following the completion of the primary treatment upgrades has shown the Northern District WWTP has an operational capacity to treat wastewater to primary treatment standards of up to 9 MGd (34 MLd). It should be noted this limit is imposed by the 2011 Court Order, and is not a hydraulic limitation as the plant has a design capacity of 12 MGd (45 MLd). Issuance of the 2013 NPDES permits established effluent quality requirements consistent with secondary treatment and Guam Water Quality Standards, including those for nutrients. The Northern District WWTP and the Agaña WWTP currently cannot meet the permitted discharge limits, and are in non-compliance with the NPDES permit. Connection to a WWTP that does not meet NPDES permit conditions is a significant impact. As a result, the No-Action Alternative and the five proposed action alternatives would have similar significant impacts. The potential mitigation measure for the No-Action Alternative would be to seek other funding to upgrade these wastewater treatment plants in total capacity, treatment systems, and other wastewater infrastructure improvements.

Solid Waste

For the No-Action Alternative, impacts to solid waste would be similar to those described in the 2010 Final EIS (Volume 6, Chapter 3: Utilities, Section 3.2.5: Solid Waste, pages 3-81 to 3-83). However, the solid waste existing condition on Guam has changed significantly since the 2010 Final EIS was issued. This change is due to the opening of the new GovGuam Layon Landfill at Dandan. Now that this landfill is open, all acceptable MSW from existing DoD facilities on Guam is disposed at Layon Landfill. Required transfer stations and road improvements have also been completed and are operational. Less than significant impacts to solid waste would occur for both the No-Action Alternative and the action alternatives discussed in Chapter 4. Although impacts would be similar, the estimated increase in solid waste generation under the proposed action alternatives would be roughly 1/3 that of the No-Action Alternative. This would extend the life of the Layon Landfill over that under the No-Action Alternative.

Information Technology and Communications

The IT/COMM requirements for the No-Action Alternative would be similar to that for the action alternatives discussed in Chapter 4, with a less than significant impact, with the potential for brief outages during construction. The No-Action Alternative intra-base (cantonment area and family housing areas) would require a somewhat larger communication network because these areas would be larger than the action alternatives. However, the intra-base and off-base connectivity requirements would be the same in order to meet the Marine Corps IT/COMM criteria.

4.6.15 Socioeconomics and General Services

For the No-Action Alternative, the potential population, economic, public service, sociocultural, and land acquisition impacts would be the same as those described in the 2010 Final EIS (Volume 2, Chapter 16: Socioeconomics and General Services, Section 16.2.2: Proposed Action, pages 16-73 to 16-156). The action alternatives discussed in Chapter 4 would be substantially different from the No-Action Alternative. The population projections for the action alternatives are of a substantially lesser magnitude
than those presented in the No-Action Alternative due to a change in the proposed action being analyzed, including:

- Fewer active duty Marines - compared to the No-Action Alternative, the number of active duty Marines would be 42% lower for the action alternatives (from 8,552 to 5,000).
- Fewer military dependents of active duty Marines - military dependents are lower by 86% (from approximate 9,000 to approximately 1,300). The disproportionate decline in the number of dependents is due to a change in composition of active duty Marines. Under the action alternatives, two-thirds of active duty Marines would be rotational - spending 6 months per deployment to Guam - and would not be accompanied by dependents.
- Singular focus on the Marine Corps relocation - compared to the No-Action Alternative, the action alternatives do not assess impacts related to a potential DON nuclear-powered aircraft carrier berthing or a potential AAMDTF, or any connected actions such as roadways or utilities construction that are not directly associated with cantonment or LFTRC operations.
- An extended construction period - construction work resulting from implementation of the proposed action is expected to begin in 2015; construction would ramp up for a couple of years and then an extended period of construction activity would occur from 2017 through 2023, and then begin to taper off from 2024 until the final year of construction in 2027.

The action alternatives analyzed in Chapter 4 would avoid such a population peak and many of the social problems that can result from sharp population increases and subsequent sharp declines in population (a “Boomtown” economy, Appendix D).

### 4.6.16 Hazardous Materials and Waste

For the No-Action Alternative, the environmental impacts associated with hazardous materials and waste would be the same as those described for the preferred alternative (Alternative 2) in the 2010 Final EIS (Volume 2, Chapter 17: Hazardous Materials and Waste, Section 17.2.3: Preferred Alternative (Alternative 2), page 17-55). The No-Action Alternative would result in less than significant impacts from hazardous materials and waste but the amount of hazardous materials and waste used and generated would be 64% greater than the levels described for the action alternatives discussed in Chapter 4 due to the increased personnel and operations under the No-Action Alternative.

### 4.6.17 Public Health and Safety

For the No-Action Alternative, impacts to public health and safety would be the same as those described for the preferred alternative (Alternative 2) in the 2010 Final EIS (Volume 2, Chapter 18: Public Health and Safety, Section 18.2.3: Alternative 2 (Preferred Alternative), page 18-23). The No-Action Alternative and the action alternatives discussed in Chapter 4 would result in similar impacts to public health and safety with less than significant impacts during construction and no impacts during operations, except for Alternative C and Alternative E, which would have a significant, unmitigable impact associated with operational safety (explosives safety).

### 4.6.18 Environmental Justice and the Protection of Children

For the No-Action Alternative, the potential environmental justice and the protection of children impacts would be the same as those described for the preferred alternative (Alternative 2) in the 2010 Final EIS (Volume 2, Chapter 19: Environmental Justice and Protection of Children, Section 19.2.3: Preferred Alternative (Alternative 2), pages 19-18 to 19-19). There would be no significant noise impacts, and no land acquisition impacts disproportionately affecting minority and low-income populations. The
magnitude of potential impacts to environmental justice under the No-Action Alternative would be larger than the potential impacts under the action alternatives discussed in Chapter 4, due to the increased scope and size of the No-Action Alternative. The action alternatives would avoid or significantly reduce environmental justice issues that can result from a substantial and rapid influx of people to a single island location, as proposed in the No-Action Alternative. There would be no significant noise impacts under the action alternatives. In addition, impacts to the economy, public health services, and social services relating to environmental justice would be reduced. The “boom and bust” cycle of population growth and decline proposed in the No-Action Alternative would be substantially alleviated under the action alternatives, reducing potential adverse impacts to the economy (and thus to low-income residents). Access to public health and social services would continue to be problematic under the action alternatives due to the increase in population accessing these services, but the level of strain to public health and social services would be lessened.

4.7 SUMMARY OF IMPACTS AND POTENTIAL MITIGATION MEASURES FOR THE MAIN CANTONMENT/HOUSING ALTERNATIVES

Table 4.7-1 summarizes the impacts and potential mitigation measures of each cantonment/family housing alternative, including the No-Action Alternative. BMPs to minimize impacts would be employed during construction (see Section 2.8). Significant impacts are highlighted in yellow in Table 4.7-1 and any potential mitigation measures are identified immediately following the associated impact.
Sinkholes.

Since no sinkhole hydrogeologic assessment to ensure adverse impacts expected. Potential over the longer term due to substantially larger impervious surface area (883 acres [357 ha]) compared to the construction alternatives. No prime farmland is identified in the development footprint. Under Alternative B, 41 features were preliminarily identified as topographic features that may contain sinkholes. Impacts and BMPs would be as described for Alternative A. Under Alternative C, 28 features were preliminarily identified as topographic features that may contain sinkholes. Impacts and BMPs would be as described for Alternative A. No adverse impact given compliance with 22 GAR Chapter 10 § 10106F for protection of sinkholes, so there would be no adverse impacts to sinkholes.

</table>
| SI-M                     | Long-term increase in annual groundwater production of 1.7 MGd could result in a localized significant impact to the NGLA. Also, further deterioration to the existing GWA interceptor sewer system from AAFB to the Northern District WWTP could result in failure and significant impacts to groundwater quality from wastewater leaks. | Potential Mitigation Measures
The DoD would, as appropriate, implement enhanced water conservation measures for the proposed action, improve existing DoD water systems to reduce system leaks, adjust pumping rates at DoD wells, use existing wells, and/or increase the use of surface water from Fena Reservoir, in order to reduce withdrawals from the NGLA. The DoD would continue to support the GWRDG and would support USGS’s recommendation to rehabilitate and expand the hydrologic data collection network and monitoring necessary to ensure sustainable management of NGLA. As required in the FY 2014 NDA, the EAC implementation plan will address public infrastructure requirements necessary to support the preferred alternative, as well as address groundwater-related issues including technical and financial assistance for an updated and expanded NGLA monitoring well network and the refurbishment of the GWA interceptor sewer from AAFB to the Northern District WWTP. The implementation plan will detail descriptions of work, costs, and schedules for completion of construction, improvements, and repairs to Guam public infrastructure affected by the realignment, including improvements and upgrades to the NGLA monitoring well network. To support this implementation plan, DoD assessed GWA’s water and wastewater potential for sewage spill from increased flow through the GWA interceptor sewer system would be the same as under Alternative A. Mitigation would be the same as under Alternative A. | Potential Mitigation Measures

Note: The table above provides a summary of the impacts and potential mitigation measures for the Cantonment/Family Housing Alternatives. The impacts are classified based on their significance, with SI representing significant impacts, SI-M indicating significant impact-mitigable, LSI denoting less than significant impacts, NI signifying no impacts, and BI designating beneficial impacts. The table includes detailed descriptions of the impacts and the proposed mitigation measures for each alternative. The summary highlights key environmental considerations, such as changes in aquifer recharge rates and nearshore water quality, and the actions taken to mitigate these effects. The table also indicates the level of compliance with regulatory standards and the anticipated timing of actions to address non-compliance. The summary is informed by the Guam Military Relocation Act (Public Law No. 113-76) appropriated $106.4 million to the Secretary of Defense, acting through the OEA, for civilian water and wastewater improvements on Guam. These funds will remain available until expended.

Legend: SI = significant impact; SI-M = significant impact-mitigable; LSI = less than significant impact; NI = no impact; BI = beneficial impact.
preferred alternative. The implementation plan will detail descriptions of work, costs, and schedules for completion of construction, improvements, and repairs to Guam public infrastructure affected by the realignment, including improvements and upgrades to the Guam wastewater system. The water and wastewater assessment that DoD prepared to support the Implementation Plan recommended upgrades to the Northern District WWTP and the refurbishment of the GWA interceptor sewer from AAFB to the Northern District WWTP. Section 8102 of the FY 2014 Consolidated Appropriations Act (Public Law No. 113-76) appropriated $106.4 million to the Secretary of Defense, acting through the OEA, for civilian water and wastewater improvements on Guam. These funds will remain available until expended.

### Finegayan (Alternative A)

- **NI**: No direct or indirect impact from stormwater runoff discharge from the project area to nearshore waters.
- **LSI**: Minor increase in runoff volume and pollutant loading potential.

### Finegayan/South Finegayan (Alternative B)

- **NI**: Impacts would be similar to Alternative A, except that there would be greater vegetative cover than under Alternative A.

### Andersen Air Force Base (Alternative C)

- **NI**: Impacts would be similar to Alternative A.

### Barrigada (Alternative D)

- **NI**: Impacts would be similar to Alternative A.

### Finegayan/Andersen Air Force Base (Alternative E)

- **NI**: Impacts would be similar to Alternative A.

### No-Action Alternative

- **LSI**: Minor increase in runoff volume and pollutant loading potential.

**Potential Mitigation Measures**

Mitigation would be the same as defined in the 2010 ROD.
Traffic congestion and mobile source air toxics from increased long-term operational phase off-road vehicle CO, PM, and MSATs emissions within both Piti and Tanguisson nonattainment areas would be less than or similar to those under Alternative A. The hot-spot traffic congestion impacts along the truck routes off-site on road vehicle CO, PM, and MSATs hot-spot impact concentrations for Alternative E would be similar in magnitude to those predicted for Alternative A. Project impacts of all non-carcinogenic and all non-carcinogenic MSATs are considered acceptable. Project impacts of all non-carcinogenic MSATs are also considered acceptable.

Operation Impacts

Direct and indirect impacts associated with long-term operational phase off-base roadway hot-spot particulate matter, carbon monoxide, and mobile source air toxics from increased traffic congestion.

Impacts would be similar to Alternative A. In addition, because AAFB is a Prevention of Significant Deterioration source, a permit modification could be required as a result of the proposed project. This determination would be made during the final design stage to ensure that the development on AAFB would be in compliance with applicable regulatory requirements.

Impacts would be similar to Alternative A. The estimated traffic congestion conditions under Alternative E would be comparable to those for Alternatives A and C. Gained the low levels of CO and MSATs impact concentrations predicted under Alternative A and the comparable traffic congestion conditions at analyzed intersections under Alternative C as compared to Alternative A, the hot-spot impact of off-site on-road vehicle CO and MSATs emissions under Alternative E during operational years would be less than or similar to those under Alternative A. Based on these findings, long-term operational phase air quality impacts under Alternative E are considered less than significant.

<td>Construction Impacts</td>
<td>LSI Direct and indirect impacts from construction noise. Short-term construction noise affecting the nearest receptors at Finegayan would be 65.4 dB L$<em>{eq}$, which is below USEPA threshold guideline of 75 dBA L$</em>{eq}$. Receptors include 20 houses (70-75 people) along Route 3. Long-term noise emanating from the center of the cantonment/family housing area would be 54.9 and 51.5 dBA L$_{eq}$, respectively, and be below PUCUN guidelines.</td>
<td>LSI Direct and indirect impacts from construction noise. Short-term construction noise affecting the nearest receptors at Finegayan would be 74.8 dB L$<em>{eq}$ for family housing and 59 dBA L$</em>{eq}$ for cantonment. Similar to Alternative 1; 20 homes (36 people) would be impacted. Long-term noise emanating from the center of the cantonment/family housing area would be 50.4 and 57.8 dBA L$_{eq}$ respectively, and be well below PUCUN guidelines.</td>
<td>LSI Direct and indirect impacts from construction noise. Short-term construction noise affecting the nearest receptors at Andersen AAFB would be 74.8 dB L$<em>{eq}$ and within acceptable limits. 25 homes (92 people) would be impacted, which is the greatest and only slightly more than Alternative A. The extended construction period would further lessen impacts. Long-term noise emanating from the center of the cantonment/family housing area would be 62.4 and 56.4 dBA L$</em>{eq}$ respectively, and be well below PUCUN guidelines.</td>
<td><strong>LSI</strong> Impacts would be similar to Alternative A and C. Direct and indirect impacts from construction noise. Short-term construction noise affecting the nearest receptors at Finegayan would be 65.4 dB L$_{eq}$ and within acceptable limits. 20 homes (70-75 people) would be impacted, which is similar to Alternative A.</td>
<td><strong>LSI-M</strong> Construction noise would impact residences along Route 3. Impacts would be less than significant or significant but mitigable, depending on the location of construction activities.</td>
<td></td>
</tr>
<tr>
<td>Operation Impacts</td>
<td><strong>LSI</strong> Long-term direct impact. Traffic noise would be below 66 dB and comply with Guam Department of Public Works guidelines. Long-term operations would be similar to an office park/residential setting.</td>
<td>Impacts would be similar to Alternative A. However, there would be slightly more traffic in a 1 mile (1.6 km) stretch.</td>
<td>Impacts would be similar to Alternative A. However, traffic noise would be less than other alternatives.</td>
<td>LSI Impacts would be similar to Alternative A. However, steady state noise would be primarily due to ongoing aircraft noise. Traffic noise would be reduced using sound reducing devices on construction equipment and periodic inspection of machinery.</td>
<td><strong>LSI-M</strong> Noise impacts would occur as a result of traffic noise.</td>
<td></td>
</tr>
</tbody>
</table>

### Noise Mitigation Measures

- **LSI** Construction associated with the cantonment/family housing facilities consist of support, maintenance/storage, housing, and non-live fire training functions; there would be no changes to airspace.
- **LSI** Impacts would be similar to Alternative A.
- **LSI** Operation and functions associated with the cantonment/family housing facilities consist of support, maintenance/storage, housing, and non-live fire training functions; there would be no changes to airspace.
- **LSI** Impacts would be similar to Alternative A.
- **LSI** Impacts would be similar to Alternative A.

**Legend:** SI = significant impact; SI-M = significant impact-mitigable; LSI = less than significant impact; NI = no impact; BI = beneficial impact.

**Potential Mitigation Measures**

Upgrading the Northern District WWTP to secondary treatment standards and Guam Water Quality Standards, including those for nutrients (as required by the 2013 NPDES permit), would mitigate significant impacts to marine biological resources. The FY 2014 NDAA requires the EAC to develop an implementation plan that addresses assistance to public infrastructure requirements necessary to support the preferred alternative. The implementation plan will detail descriptions of work, costs, and schedules for completion of construction, improvements, and repairs to the Guam wastewater system. The water and wastewater assessment that DOE prepared to support the Implementation Plan recommends upgrades to the Northern District WWTP and the refurbishment of the GWA Interceptor sewer from AAFP to the Northern District WWTP. Section 8102 of the FY 2014 Consolidated Appropriations Act (Public

### Essential Fish Habitat

**SI**
- Increasing wastewater discharge from a non-compliant treatment plant could result in significant indirect impacts to essential fish habitat during the period of non-compliance.

**Potential Mitigation Measures**
Upgrading the Northern District WWTP to secondary treatment standards (as required by the 2013 NPDES permit) would mitigate significant impacts to marine biological resources. The FY 2014 NDAA requires the EAC to develop an implementation plan that addresses assistance to public infrastructure requirements necessary to support the preferred alternative. The implementation plan will detail descriptions of work, costs, and schedules for completion of construction, improvements, and repairs to Guam public infrastructure affected by the realignment, including improvements and upgrades to the Guam wastewater system. The water and wastewater assessment that DoD prepared to support the Implementation Plan recommends upgrades to the Northern District WWTP and the refurbishment of the GWA interceptor sewer from AAFB to the Northern District WWTP. Section 8102 of the FY 2014 Consolidated Appropriations Act (Public Law No. 113-76) appropriated $106.4 million to the Secretary of Defense, acting through the OEA, for civilian water and wastewater improvements on Guam. These funds will remain available until expended.

**Impacts would be similar to Alternative A.**

**Potential Mitigation Measures**
Mitigation would be the same as under Alternative A.

**LSI**
- Mitigation would be the same as under Alternative A. The water and wastewater system in the area of the proposed footprints of Andersen and Barrigada would be upgraded to meet secondary treatment standards (as required by the 2013 NPDES permit) to mitigate impacts. The Guam WWTP and Northern District WWTP upgrade would be designed and implemented consistent with the mitigation measures developed for the preferred alternative. A non-compliant treatment plant greater than slightly reduced since the Finegayan cantonment would be developed further from the coast, thus minimizing impacts.

**LSI**
- Mitigation would be the same as under Alternative A.

Cultural Resources

**Construction Impacts**

SI-M: Potential direct adverse effects to 21 historic properties, including 11 historic properties within the cantonment and housing area and undetermined effects to 7 unevaluated buildings.

Potential impacts to culturally important natural resources from vegetation removal.

Potential Mitigation Measures:

- **Proposed mitigation through 2011 PA processes, including data recovery and contractor measures, and coordination with SHPO, concuring parties, and knowledgeable traditional practitioners.**

**Operation Impacts**

SI-M: Potential indirect adverse effects to one NRHP-eligible archaeological site/potential traditional cultural property due to increased recreation use.

Potential Mitigation Measures:

- **Proposed mitigation through the 2011 PA stipulation on Cultural Resources Awareness orientation and educational signage.**

**Visual Resources**

LSI: Short-term direct impacts from presence of construction equipment.

- **Impacts would be similar to Alternative A.**

Potential Mitigation Measures:

- **Prepare Installation Appearance Plan and implement design guidelines for all buildings.**

- **Minimize impact by using native flora to create a natural-appearing “screen” around the cleared range areas, outside of the firebreaks/perimeter roads.**

- **Develop and implement a landscape plan focused on retention of mature specimen trees during construction (where possible).**

<tr>
<td>The new Layon Landfill has the capacity to accommodate the projected MSW for the reduced levels of the current proposed action. The C&amp;D debris that cannot be recycled or reused, and wastes that are prohibited at Layon Landfill would be disposed at the Naval Base Guam Landfill and permitted private landfill facilities. All green waste would be processed for reuse. The DON is currently coordinating with the GSP regarding the status of the permit for the Naval Base Guam Landfill. The proposed action would be consistent with solid waste permit terms and conditions.</td>
<td>No long-term, directs impacts as electrical power distribution system has been developed to handle the increased demand from the proposed action and proposed improvements to electrical transmission systems would accommodate future demand. The island-wide electrical power generating system owned and operated by the GPA has adequate capacity to provide for the additional demands from the proposed action. With the proposed improvements to electrical transmission systems and measures to minimize outages during construction, long- and short-term direct impacts to the electrical systems would be less than significant.</td>
<td>Short-term interruption to commercial service during rerouting of duct banks during construction. Commercial IT/COMM would need to be expanded into the proposed new development and would add users, presenting a minimal short-term, direct impact to current users.</td>
<td>Impacts would be similar to Alternative A. Minimal potential for short- or long-term adverse environmental consequences to the existing DoD IT/COMM facilities at AAFB. Direct impact from short-term lack of commercial service during the construction phase.</td>
<td>Impacts would be similar to Alternative A. For the proposed housing area at Barrigada, there are several existing DoD IT/COMM lines, but no commercial lines. The proposed housing area has been designed around those existing lines using the best available information on their locations. It is possible that these lines could be impacted during construction. Should the locations of these existing lines be different from available information, the lines might require relocation or the proposed development might require revisions to avoid the existing lines.</td>
<td>Short-term interruption to commercial service during rerouting of duct banks during construction. Commercial IT/COMM would need to be expanded into the proposed new development areas at both Finegayan (main cantonment) and AAFB (housing) and would add users, presenting a minimal short-term, direct impact to current users.</td>

Potential Mitigation Measures

- The DoD would, as appropriate, implement enhanced water conservation measures for the proposed action, improve existing DoD water systems to reduce system leaks, adjust pumping rates at DoD wells, use existing wells, and/or increase the use of surface water from Fena Reservoir to reduce withdrawals from the NGLA. The DoD would continue to support the GWRDG and would support USGS's recommendation to rehabilitate and expand the hydrologic data collection network and monitoring necessary to ensure sustainable management of NGLA.

- Expansion/rehabilitation of the NGLA monitoring well network would mitigate significant impacts. The FY 2014 NDAA directed the Secretary of Defense to convene the EAC in part to develop an implementation plan that will address public infrastructure requirements necessary to support the preferred alternative. The implementation plan will detail descriptions of work, costs, and schedules for completion of construction, improvements, and repairs to Guam public infrastructure affected by the realignment, including rehabilitation and expansion of the NGLA monitoring well network. The water and wastewater assessment that DoD prepared to support the Implementation Plan recommended an updated and expanded NGLA monitoring well network. Section 802 of the FY 2014 Consolidated Appropriations Act (Public Law No. 113-76) appropriated $106.4 million to the Secretary of Defense, acting through the OEA, for civilian water and wastewater improvements on Guam. These funds will remain available until expended.

Legend:  
SI = significant impact; SI-M = significant impact-mitigable; LSI = less than significant impact; NI = no impact; BI = beneficial impact.

</tr>
<tr>
<td>Operation of the cantonment/family housing facilities under Alternative A would result in significant direct impacts during the period of non-compliance with the 2013 NPDES permit at the Northern District WWTP. However, upgrades to bring the Northern District WWTP into compliance with the permit are expected to be completed early in the operational phase of the proposed action so operation impacts would therefore be significant but mitigable. The existing GWA interceptor sewer system is in a state of deterioration and needs to be refurbished. Increased flow from the proposed action would accelerate this deterioration and could lead to failure of the sewer system. This would represent a significant but mitigable impact.</td>
<td>Impacts would be similar to Alternative A. Potential Mitigation Measures Mitigation would be the same as under Alternative A.</td>
<td>Impacts would be similar to Alternative A. Potential Mitigation Measures Mitigation would be the same as under Alternative A.</td>
<td>Impacts would be similar to Alternative A. However, impacts would result from permit noncompliance and increased wastewater flows from both Northern District WWTP and Agaña WWTP. Potential Mitigation Measures Mitigation would be the same as under Alternative A.</td>
<td>Impacts would be similar to Alternative A. Potential Mitigation Measures Mitigation would be the same as under Alternative A.</td>
<td>SI-M For the No-Action Alternative, impacts to wastewater would be similar to those described in the 2010 Final EIS (Volume 6, Chapter 3: Utilities, Section 3.2.4 Wastewater, pages 3-69 to 3-81), with the additional significant but mitigable impact to the collection system from AAFB to the Northern District WWTP. Potential Mitigation Measures Mitigation would be the same as described in the 2010 ROD with the addition of refurbishment of the existing collection system from AAFB to the Northern District WWTP.</td>
</tr>
</tbody>
</table>

Legend: SI = significant impact; SI-M = significant impact-mitigable; LSI = less than significant impact; NI = no impact; BI = beneficial impact.
The difference would be 4.1%. However, the higher than it otherwise would have been.

Between the years 2021 and 2023 the proposed Marine Corps relocation would be considered significant during both the construction and operation phases of the proposed action. At a steady-state the difference would be 4.1%. However, the significant change would not be considered entirely negative. Impacts related to population change would be mixed, with some adverse and some beneficial outcomes, as noted in the following subsections.

*LSI: Project design would avoid overlap with contaminated sites. Various BMPs and construction operational protocol would be followed if relocation of construction projects is not possible. Special design techniques and methodology would be required to ensure the long-term structural integrity of proposed construction projects.*

*Toxic Substances: Demolition of older buildings and/or utilities may result in encountering PCBs, ACM and LBP that were used in the older building materials. Toxic substances would not be utilized for new construction. Because the proposed construction areas are located in a USEPA Radon Zone 1, it is possible that new buildings, facilities, and structures could encounter radon intrusion. To minimize this impact, radon resistant construction techniques and potential mitigation systems would be incorporated into the building/facility designs. In addition, DoD would periodically test facilities constructed in known radon zones to verify that no unacceptable radon gas buildup occurs and install radon mitigation systems as appropriate.*

*Operation Impacts:*

-Hazardous Materials Management:
- **LSI**: Long-term, direct impact from increase in transportation/transfer of hazardous materials, primarily from use of POL. Current hazardous materials handling, storage, and disposal capacity is sufficient. BMPs and SOPs would minimize potential direct or indirect impacts. Training use would be in compliance with MCO P5900.2A. Existing hazardous waste accumulation sites would be maintained to support the proposed cantonment/family housing area and a 90-day accumulation area would be provided. In addition, an undetermined number of satellite accumulation sites would be created, as needed, in proximity to hazardous materials use and hazardous waste generation to support cantonment activities.

-Hazardous Waste Management:
- **LSI**: Increase in transportation/transfer of hazardous waste on Guam from increased population. New satellite hazardous waste storage areas would be created in proximity to hazardous materials use and hazardous waste generation, and would be managed with applicable regulations.

**Legend:** SI = significant impact; SI-M = significant impact-mitigable; LSI = less than significant impact; NI = no impact; BI = beneficial impact.

Environmental Health Effects:

LSI Similar to the construction impacts, operations would result in less than significant direct impacts due to long-term operations noise. Operations would result in less than significant direct impacts to water quality as a result of increased long-term demand and potential water related illness.

NSI Similar to construction impacts, operations would result in no impacts to hazardous substances use.

Hazardous Substances:

NSI Similar to construction impacts, operations would result in no impacts to hazardous substances use.

Unexploded Ordnance:

LSI Similar to the construction impacts, operations would result in less than significant direct impacts relative to potential contact with UXO.

Traffic Incidents:

LSI Similar to the construction impacts, operations would result in less than significant long-term impacts due to potential increase in traffic incidents.

Legend: SI = significant impact; SI-M = significant impact-mittigable; LSI = less than significant impact; NI = no impact; BI = beneficial impact.

**Public Health and Safety**

SI-M: Since the number of public health and safety professionals required to maintain current levels of service at public health and safety agencies would increase by more than 2%, and due to existing deficiencies in facilities and equipment at these agencies, there would be short-term, direct and indirect significant impacts to public health agencies and significant direct and indirect impacts on public safety agencies, both short-term (during construction) and during the steady-state period (during operation).

Given that public health agencies that serve low-income and uninsured populations already have insufficient staffing levels, population increase would further strain these resources, causing a significant environmental justice impact.

**Potential Mitigation Measures**

The DoD would continue to support the efforts of the CMCC to develop recommendations, as appropriate, regarding adjustment of construction tempo and sequencing to directly influence workforce population levels and indirectly influence induced population growth before infrastructure capabilities are exceeded. Such support may include providing project-related employment and population forecasts, participating in the identification of shortfalls in Guam public services, and assisting in the identification of federal programs and funding sources that may help GovGuam to address shortfalls.

The FY 2014 Consolidated Appropriations Act (Public Law No. 113-76) appropriated $13,000,000 for the construction of a regional public health laboratory on Guam.

CHAPTER 5

AFFECTED ENVIRONMENT AND ENVIRONMENTAL CONSEQUENCES AT LIVE-FIRE-TRAINING RANGE COMPLEX SITE ALTERNATIVES

This chapter describes the affected environment and potential environmental consequences associated with the LFTRC component of this SEIS proposed action. As shown in the box at right, this is the second of three major sections of this SEIS that analyze the direct and indirect impacts of the 2012 Roadmap Adjustments. The impacts associated with the cantonment alternatives are addressed in Chapter 4 and the impacts that are unique to specific combinations of a cantonment/family housing alternative and an LFTRC alternative are addressed in Chapter 6.1. When considered in conjunction with the related Marine Corps actions that remain final under the 2010 ROD, as is done in Chapter 6.2, the resulting “collective” impacts represent the total impacts related to the proposed Marine Corps relocation to Guam.

Chapter 5 is structured around each of the five action alternatives for the LFTRC plus the No-Action Alternative, with associated subsections to address the 18 environmental resource areas that were evaluated for each alternative. The Affected Environment subsection for each resource area describes the baseline environmental conditions in the proposed project areas. These baseline conditions provide a comparative framework for evaluating the impacts to each resource, which are presented in the Environmental Consequences subsections. In compliance with CEQ regulations implementing NEPA, the environmental consequences discussion includes both direct and indirect impacts. The impact analyses also take into account the implementation of the BMPs included in the proposed action as described in Chapter 2 of this SEIS. At the end of Chapter 5, following the impact analysis for each LFTRC is a table that summarizes the impacts and potential mitigation by alternative for each resource subsection (Table 5.7-1).

The box at right summarizes the elements of the proposed action for the LFTRC that are analyzed in this chapter. These include the construction and operation of the LFTRC at one of the five alternative sites, associated utility infrastructure both on- and off-site, and the construction and operation of the HG Range at Andersen South.
As appropriate to each alternative and each resource area, applicable information from the 2010 Final EIS that remains relevant in the context of this SEIS is incorporated by reference and briefly summarized. Each subsection then places particular emphasis on updating any key resource information that changed since the 2010 Final EIS, and on presenting any new information regarding baseline conditions or environmental consequences that was not included in the 2010 Final EIS.

5.1 **ROUTE 15 LIVE-FIRE TRAINING RANGE COMPLEX - ALTERNATIVE 1**

Under Alternative 1, the proposed development of a live-fire training range complex would occur on land crossed by Route 15 adjacent to Andersen South. Details about this alternative are provided in Section 2.5.4.1 and the proposed site is illustrated in Figure 2.5-2.

5.1.1 **Geological and Soil Resources**

5.1.1.1 Affected Environment

The affected environment for geological and soil resources associated with Route 15 LFTRC Alternative 1 is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 3: Geological and Soil Resources, Section 3.1.3.3: Non-DoD Land which is summarized below for reference. The affected environment for geological and soil resources associated with the stand-alone HG Range at Andersen South is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 3: Geological and Soil Resources, Section 3.1.3.1: Andersen South). The proposed reduction in the number of relocating Marines and dependents under the proposed action does not alter the description of the affected environment for geological and soil resources, but it would reduce some potential impacts to geological and soil resources that were determined to be less than significant or mitigated to less than significant in the 2010 Final EIS, as described in the analysis of environmental consequences for Alternative 1 below.

Route 15 LFTRC Alternative 1 would be located in a topographically hilly area on the eastern side of Guam’s northern limestone structural province. Within the proposed project footprint, the ground surface slopes downward from northeast to southwest. Elevations range from approximately 300 feet (91 m) above MSL on the slope between Pågat Plateau and Sasayan Valley east of Route 15 to approximately 560 feet (171 m) MSL on a ridge approaching Lujuna Peak north of Pågat Plateau. East of Pågat Plateau is a steep cliffline that drops down to the Sasayan Valley below and then to the Pacific Ocean. All construction for Route 15 LFTRC Alternative 1 would take place on the limestone plateau. The only Alternative 1-related improvements below the plateau would consist of a line of warning signs posted on the range boundaries and along the shoreline.

The HG Range site at Andersen South is located about 0.6 mile (0.9 km) to the west of Alternative 1. The proposed site of the HG Range stands at an elevation of approximately 374 feet (114 m) MSL, at the crest of a gentle ridge.

Bedrock underlying the Route 15 LFTRC Alternative 1 footprint and the HG Range site is young (Mariana) limestone, the geologic setting for sinkhole formation (see Section 3.1.1.1). One major and one minor bedrock fault cross the length of the Alternative 1 footprint, trending from northeast to southwest roughly parallel with Route 15 (Figure 5.1.1-1). No bedrock faults are mapped in the HG Range footprint. Other major and minor bedrock faults are mapped to the northeast of the proposed Alternative 1 footprint. Based on available topographic and field data, three features have been preliminarily identified as sinkholes/depressions that may contain sinkholes within, or on the perimeter of, the proposed Route 15 LFTRC Alternative 1 footprint.

Guam Urban Land Complex, Guam Cobbly Clay Loam, and Ritidian-Rock Outcrop Complex comprise the soils of Route 15 LFTRC Alternative 1. The HG Range site soil consists of Guam Cobbly Clay Loam (Figure 5.1.1-2). Guam Cobbly Clay loam is shallow well-drained soil, runoff is slow, and the water erosion hazard is slight (Young 1988). For the Ritidian-Rock Outcrop Complex soil, runoff is very slow and the water erosion hazard is slight (Young 1988). Urban Land comprises land covered by roads, buildings, parking lots and other impervious surfaces (Young 1988).

Subsistence farming currently takes place on less than 1% of the undeveloped land in the proposed acquisition area for Alternative 1 (see Section 5.1.6 of this SEIS). The land where the HG Range would be constructed is located inside Andersen South and used for military purposes. Prime farmland soils, as defined by the USDA, are soils best suited to producing food, seed, forage, fiber and oilseed crops, favorable for economic production and sustained high yield, with minimal inputs of energy and resulting in least damage to the environment (Young 1988). None of the soils in the Alternative 1 and HG Range footprints are identified by USDA as prime farmland (Young 1988).

5.1.1.2 Environmental Consequences

Potential geology and soil impacts addressed in this section are limited to elements of the proposed action that could affect onshore landforms or that could be affected by geologic hazards. Potential soil contamination issues are addressed in Section 5.1.16.2 of this SEIS (Hazardous Materials and Waste).

Construction

Construction of the Route 15 realignment would be similar to the description in the 2010 Final EIS (Volume 2, Chapter 3: Geological and Soil Resources, Section 3.2.2.2: Non-DoD Land), which is summarized below for reference. Route 15 would be moved into Andersen South about 0.3 mile (0.5 km) north of its current alignment (Figure 2.5-2 in Section 2.5.4.1 of this SEIS). The new Route 15 would be constructed below grade for 1.2 miles (1.9 km) of its 1.7-mile (2.8 km) length. Its average distance (depth) below grade would be 12 feet (3.7 m). Construction of the Route 15 realignment would involve clearing, grubbing, soil moving and mass grading for proper highway grade. Earthwork for construction of the Route 15 realignment would include 323,509 yd$^3$ (247,340 m$^3$) of excavation (cut) and 34,837 yd$^3$ (26,635 m$^3$) of fill, resulting in a net 288,672 yd$^3$ (220,705 m$^3$) of cut.

Construction of the new ranges, range support building, roads, bridges, and related infrastructure associated with Alternative 1 would include clearing, grubbing and grading, and excavation (cut) and filling. Earthwork for Alternative 1 range construction would include 2,488,676 yd$^3$ (1,902,730 m$^3$) of cut and 2,451,937 yd$^3$ (1,874,640 m$^3$) of fill, resulting in a net of 36,740 yd$^3$ (28,090 m$^3$) of cut. Alternative 1 would involve a smaller excavation volume than Alternatives 3 and 4, and a larger volume than Alternatives 2 and 5 (Alternative 3 would involve the greatest; Alternative 2 would require the least).

Within the Alternative 1 footprint, there are major differences in elevation in the areas planned for construction of the MPMG Range, MRF Range and KD Rifle Range. There would be substantial changes to surface elevation for construction of the MPMG Range, MRF Range and KD Rifle Range. Because of the major elevation changes, the substantial alteration of the surrounding landscape, and the amount of excavation, filling and contouring that would occur; construction of the Alternative 1 is expected to have a significant direct, long-term impact on topography.

Construction of the HG Range at Andersen South would involve 8,894 yd$^3$ (6,800 m$^3$) of cut and 12,641 yd$^3$ (9,665 m$^3$) of fill, for a net of 3,747 yd$^3$ (2,865 m$^3$) of fill. The 36,740 yd$^3$ (28,090 m$^3$) of cut generated by construction of the other Alternative 1 ranges would provide sufficient additional fill to supply the need at the HG Range.
Figure 5.1.1-2
Soils in the Vicinity of Route 15 LFTRC Alternative 1

Sources: NAVFAC Pacific 2013; NRCS 2006
Potential mitigation is not considered feasible for this impact because smaller cut/fill volumes would not provide the necessary level surfaces for the referenced ranges and roadway. This significant impact to topography would occur with implementation of any LFTRC Alternative except Alternative 2, which would involve the least amount of cut and fill (i.e., the impact would be similar for all alternatives except Alternative 2).

Construction of the HG Range without Alternative 1 would include the same activities as described for LFTRC Alternative 1, but would involve much smaller amounts of cut (8,890 yd³ [6,600 m³]) and fill (12,641 yd³ [9,645 m³], with a net 3,747 yd³ [2,865 m³]) of fill. Grading, contouring, and changes to elevation would not be substantial, so direct, long-term impacts to topography from construction of the HG Range alone would be less than significant.

There is a potential for increased erosion, compaction, and soil loss from physical disturbance caused by construction activity and changes to existing topography. However, project design and construction for realignment of Route 15, Alternative 1 ranges and the HG Range would incorporate engineering controls as BMPs to minimize erosion within the project construction footprint, as required by Title 22 of GAR, Chapter 10 Guam Soil Erosion and Sediment Control Regulations. Examples of such engineering controls include:

- Use of drainage diversion and control to temporarily direct runoff from adjacent undisturbed areas away from construction sites.
- Use of benches or terraces and drainage control on cut or fill slopes higher than 15 feet (5 m) to minimize erosion on slope faces.
- Compliance with the DoD Program-level SWPPP for construction, in addition to individual project SWPPPs during construction to reduce the potential for erosion, runoff, sedimentation, and stormwater pollutant loading.
- For each project, limit the size of the unstabilized disturbed areas to less than 20 acres (8 ha) during construction.
- Planning earth-moving operations for periods of low rainfall to minimize exposure of disturbed soil to potential runoff.
- Re-vegetating and permanently stabilizing disturbed areas as soon as possible.
- Engineering project slopes in consideration of soil and geological conditions to avoid and minimize erosion.

In addition, construction activities associated with Alternative 1 and the HG Range would comply with the Construction General Permit. Potential construction-specific stormwater BMPs would be implemented in compliance with the Construction General Permit as listed in Table 4.1.2-2. Construction-specific stormwater BMPs would provide erosion and sediment control during the construction period, generally by employing on-site measures that reduce the flow of stormwater and minimize the transport of soils and sediment off-site. Fill material would be generated on-site, whenever possible. In addition, roadway-specific BMPs, as identified in the most recent CNMI and Guam Stormwater Management Manual, would be included in the planning, design, and construction of all roadways and facilities. There would be no stream re-routing involved with construction of Alternative 1. Through compliance with 22 GAR Chapter 10 § 10106F and the Construction General Permit and implementation of roadway stormwater BMPs, and because the rate of erosion and soil loss would not be substantially increased, direct, short-term impacts to soils from erosion during construction of Alternative 1 and the HG Range would be less than significant. In addition, no indirect, short-term impacts associated with soil erosion are expected.
The soil that would be disturbed in construction of the Route 15 realignment, Alternative 1 ranges, and the HG Range is not identified as prime farmland and is used minimally for farming (Young 1988). Therefore, disturbance of soil during construction of the Route 15 realignment, Alternative 1 ranges, and the HG Range would have a less than significant direct, long-term impact to agricultural soils.

There are three topographic features that may contain sinkholes within, or on the perimeter of, the Alternative 1 footprint. No such features are identified for the HG Range footprint. However, the HG Range is underlain by limestone bedrock (see Figure 5.1.1.1). For any sinkholes discovered before or during construction, implementation of BMPs would include compliance with 22 GAR Chapter 10 § 10106F. In order to ensure compliance with 22 GAR Chapter 10 § 10106F, BMPs would be modified or an environmental and hydrogeologic assessment must be performed to ensure adverse effects will not result, including but not limited to the displacement of groundwater, interference with well production, significant changes to groundwater recharge, flooding, or the threat or introduction of any pollutant to groundwater. After a preferred alternative is selected and the ROD is signed for the proposed project, final design work would begin for the preferred alternative site. A geotechnical study, including subsurface borings, would be conducted to determine whether the depressions on the site contain sinkholes, and whether there are additional sinkholes not evident from the surface. Hydrogeological studies would be conducted to confirm groundwater flow at the site as well. The geotechnical and hydrogeological studies would be coordinated with the GEPA to design and implement an appropriate analysis. These studies would be part of the final design process and would take place before any construction begins. With implementation of these BMPs, and because no sinkholes would be filled that would adversely affect site drainage, no adverse impacts to sinkholes would occur. Therefore, construction of Alternative 1 and the HG Range would have less than significant direct, short-term impacts to sinkholes.

Hazards associated with earthquakes, fault rupture and slope instability would be minimized by adherence to UFC 3-310-04 Seismic Design of Buildings dated June 1, 2013 (USACE 2013). The realigned Route 15, Alternative 1 ranges and the HG Range would be located higher than the elevation prone to tsunamis, and so would not be susceptible to inundation. The consolidated limestone bedrock underlying the Route 15 LFTRC Alternative 1 and the proposed HG Range footprints is not subject to liquefaction. There would not be a change to soil and/or bedrock conditions that would increase vulnerability to a geologic hazard. As stated in the previous paragraph, 22 GAR Chapter 10 § 10106F requires that for sinkholes within the project development footprint that would be modified or used, an environmental and hydrogeologic assessment must be performed to ensure adverse effects will not result. Compliance with these regulations would minimize potential geologic hazards associated with sinkholes. Therefore, construction of Route 15 LFTRC Alternative 1 and the HG Range would result in less than significant direct and indirect short-term impacts with respect to geologic hazards.

Operation

Operation of the proposed Route 15 realignment, Alternative 1 ranges and the HG Range would not alter topography post construction, so no direct or indirect impacts to topography would occur.

Operational activities and conditions that may directly cause or increase naturally occurring soil erosion at a firing range would include ongoing soil disturbances resulting from vehicular and pedestrian traffic and inadequate maintenance of vegetated areas. The changes to topography caused by construction of the MPMG Range, MRF Range and KD Rifle Range and the realignment of Route 15 raise the risk of erosion during the operational phase, because graded features (cut and fill slopes) and altered surface flow patterns can potentially create conditions that may promote additional soil erosion.
The area of impervious surfaces that would be constructed for the ranges and associated infrastructure (range buildings, roads, and parking areas) would comprise approximately 30.8 acres (12.5 ha) total (see Appendix F) including about 29.9 acres (12.1 ha) for Alternative 1 and about 0.9 acre (0.4 ha) for the HG Range. There would be a minor increase in runoff from the new impervious surfaces as compared with existing conditions. Stormwater infrastructure improvements included as part of the proposed action would incorporate LID measures and BMPs as described in Section 5.1.2.2 of this SEIS to minimize soil erosion from increased runoff. Where possible, stormwater flow paths would continue to mimic pre-development flows through area topography. Stormwater BMPs that would be implemented to minimize and control runoff as described in Section 5.2.2.2 would also minimize soil erosion. Implementation of roadway-specific BMPs in the planning, design, and construction of the Route 15 realignment would minimize the potential for soil erosion associated with increased impervious surfaces and changes to elevation resulting from the realignment.

The range complex and the HG Range would be managed in accordance with current Marine Corps range management policies and procedures, which are designed to ensure the safe, efficient, effective, and environmentally sustainable use of the range area. A thorough explanation of Marine Corps range management is detailed in the 2010 Final EIS (Volume 2, Chapter 2: Description of Proposed Action and Alternatives, Section 2.3.1.4: Firing General Military Skills, pages 2-55 to 2-59). Marine Corps range management policies and procedures include procedures for removing expended rounds from live-fire ranges with impact berms, managing stormwater, controlling erosion, maintaining vegetation on berms and drainage ways and turf on the range, and restricting vehicular activities to designated/previously identified areas. Range roads would be maintained to minimize erosion.

Because the NGLA is used as a source for drinking water, prior to the construction of the ranges, both a site inspection and a site assessment, as well as actual munitions loading data, would be provided to the Marine Corps’ Range Environmental Vulnerability Assessment (REVA) and Operational Range Clearance (ORC) programs. These programs would use the site specific data to determine the appropriate frequency of monitoring and range clearance.

Under the REVA Program, site specific data would be used to evaluate the potential for MCs to reach potential receptors. This would allow the REVA program to determine whether follow-on actions would be required (e.g., sampling, additional studies) and the frequency of any further evaluations. The REVA assessment would use conservative assumptions and available site specific information to determine if modeling can be performed for lead components. Monitoring of the ranges for MCs migrating off-range would be based on the outcome of the REVA assessment. REVA assessments would begin in the first year of operation and would then be conducted at a minimum every 5 years.

The ORC program would not only consider the site-specific and REVA data but also safety and sustainability considerations in its assessment to determine the required frequency of range clearance.

Munitions constituents associated with small arms ammunition commonly used at operational ranges include lead, antimony, copper, and zinc. Lead is the primary munitions constituent indicator for small arms ranges because lead is the most prevalent (by weight) constituent associated with small arms ammunition. No specific quantitative conclusions can be made regarding the fate and transport of lead, because lead is geochemically specific regarding its mobility in the environment. Site-specific conditions are required (i.e., geochemical properties) in order to quantitatively assess lead migration. Site-specific geochemical properties are only identified via sampling and cannot be observed physically. Without site-specific physical and chemical characterization, lead cannot effectively be modeled using fate and transport modeling. The scientific community has established that metallic lead (such as recently fired,
un-weathered bullets and shot) generally has low chemical reactivity and low solubility in water and is relatively inactive in the environment under most ambient or everyday conditions. However, a portion of lead deposited on a range may become environmentally active if the right combination of conditions exists.

As indicated in the above paragraphs, a site inspection and site assessment will be completed at the range and the site-specific information provided to the REVA Manager. The REVA manager will utilize this site-specific information in their assessments of the range, which begin the first year of range operation. Assessing small arms ranges first involves defining and documenting its physical and environmental conditions, as well as how the range is utilized and maintained. The assessment process involves a review of possible factors that can influence the potential for lead to migrate off range including range use and management (source), surface water, groundwater and soil conditions, pathways and receptors (including but not limited to people, sensitive and endangered species). Upon review, if factors or a combination of factors are found to exist that would indicate possible lead migration, REVA program managers consider sampling appropriate media, identifying and implementing BMPs adjustments, or taking other steps as required.

Quarterly inspections of the range BMPs will also be performed. Inspections will lead to identifying if BMPs are still in place or if maintenance is required. Any deficiencies that cannot be immediately addressed will be reported to the Public Works Department for corrective action. Additionally, the REVA program will also evaluate BMP effectiveness and recommend adjustments as needed.

The DON will investigate additional technologies that could assist with range design and minimizing potential impacts (specific technologies or brands were not mentioned to ensure the full range of BMPs are considered). Prior to the construction of the range, the DON will perform a site survey/inspection to inform range design activities, to include evaluating the optimal site grading and any necessary soil amendments to minimize range constituent migration. Appropriate BMPs will be evaluated and incorporated into the design and construction of the range to minimize the off-site migration of stormwater runoff and reduce the infiltration of MCs (e.g. vegetation buffers, pH adjustment of soil and water quality/quantity BMPs). Designs will subsequently be coordinated and approved through Head, Range Design and Safety, Commanding General Marine Corps Combat Development Command.

There would be minor ground disturbance associated with utility maintenance. Construction stormwater BMPs would be implemented during maintenance activities to minimize and control runoff on-site and minimize potential effects of erosion.

Agriculturally-productive soils would be disturbed. Existing agricultural use of soils in the disturbed area is minimal, and the disturbed soils would not be in areas identified as prime farmland. Therefore, disturbance of these soils during the Alternative 1 and HG Range operational phase would be an adverse, but less than significant direct, long-term impact.

A potential indirect impact of firing range operations includes the possibility of live ammunition causing wildland fires. As a BMP and in accordance with range safety protocols, a Range Fire Management Plan would be prepared, based on the DON’s Wildland Fire Management Plan (USFS 2008). It would include protocols for monitoring fire conditions and adjusting training as needed. Units undergoing training at the ranges would be briefed by range control on requirements suitable to the conditions of the day and protocols should a fire occur (e.g., specifying how the range would shut down and how fire suppression action would be taken). With these measures, potential wildfires caused by the live ammunition would be unlikely. Effects to soils from erosion associated with wildfires associated with operation of Alternative 1 and the HG Range would be minimal and direct and indirect impacts would be less than significant.
With implementation of Marine Corps range management policies and procedures, fire suppression and potential mitigation measures, and stormwater BMPs (for ranges and utility maintenance), and because the rate of erosion and soil loss would not be substantially increased, less than significant direct and indirect long-term impacts to soils from erosion would occur due to Alternative 1 and HG Range operations.

The BMPs for sinkholes would be implemented in the event that maintenance activities should involve sinkholes or their immediate perimeter, so no adverse impacts to sinkholes would occur. Therefore, Alternative 1 and HG Range operations would have less than significant direct, long-term impacts to sinkholes.

Hazards associated with earthquakes, fault rupture and slope instability would be minimized by adherence to UFC 3-310-04 Seismic Design of Buildings dated June 1, 2013 (USACE 2013) during project design and construction, so direct and indirect long-term impacts with respect to seismic hazards would be less than significant. The consolidated limestone bedrock underlying Alternative 1 and the HG Range site is not vulnerable to liquefaction. The Route 15 realignment, Alternative 1 and the HG Range would be sited higher than the elevation prone to tsunamis, so they would not be susceptible to inundation. In addition, there would not be a change to soil and/or bedrock conditions that would increase vulnerability to a geologic hazard. Implementation of sinkhole BMPs would minimize potential geologic hazards associated with sinkholes. Therefore, operation of realigned Route 15, Alternative 1 and the HG Range would have less than significant direct and indirect long-term impacts associated with geologic hazards.

5.1.2 Water Resources

5.1.2.1 Affected Environment

The affected environment for water resources in the Alternative 1 project area is described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.1.3.1: Andersen South and Section 4.1.3.2: Non-federal land, pages 4-34 and 4-35). A summary of site conditions for Alternative 1 is provided in Appendix F.

Surface Water

As indicated in the 2010 Final EIS, there are no surface water resources in the Route 15 project area or the project area for the HG Range on Andersen South (Figure 5.1.2-1). Impervious areas on the Route 15 parcel amount to 71 acres (28.7 ha), or 3.5% of the total Route 15 parcel area of 2,031 acres (822 ha). Impervious areas on Andersen South amount to 132 acres (53 ha), or 6.4% of the total Andersen South area of 2,061 acres (834 ha). There are no 100-year flood zones identified within the proposed construction area. The 500-year flood zones identified within the proposed construction area are shown in Figure 5.1.2-1.

Groundwater

As indicated in the 2010 Final EIS, Route 15 land primarily overlies the Mangilao Basin and a small portion of the Yigo Basin, both of which are part of the NGLA. As also described in that document, the project area for the HG Range overlies the very permeable limestone in the Yigo Basin within the larger NGLA. The groundwater model being developed by the USGS (USGS 2013) includes the Mangilao and Yigo basins and the current well production is the same as described under Alternative A in Section 4.1.2.1 of this SEIS.
Figure 5.1.2-1
Water Resources in the Vicinity of Route 15 LFTRC Alternative 1

Sources: WERI 2001; FEMA 2007; NAVFAC Pacific 2013
Nearshore Waters

As described in the 2010 Final EIS, the Route 15 project area is located along the eastern coast of Guam along Pågat Point, and has no public beaches. Nearshore waters are mostly inaccessible to the public because there are no roads, few trails, steep terrain, and a lack of safe boat landing areas due to rough sea conditions for much of the year (Figure 5.1.2-1). The project area for the HG Range is adjacent to and inland from the Route 15 project area.

Wetlands

As indicated in the 2010 Final EIS, no wetlands were identified in the Route 15 and HG Range project areas (Figure 5.1.2-1).

5.1.2.2 Environmental Consequences

Construction

General construction impacts to water resources under Alternative 1 would be similar to those described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.1: North, pages 4-84 to 4-88) and under Alternative A in Section 4.1.2.2 of this SEIS. Under Alternative 1, there would be construction activities associated with the proposed LFTRC ranges in the Route 15 and HG Range project areas. Similar to Alternative A, Alternative 1 would occur in an area that does not contain any waters of the U.S. but would comply with the Construction General Permit as described under Alternative A.

Construction under Alternative 1 would result in the potential for short-term increases in stormwater runoff and erosion. However, through compliance with the Construction General Permit and Program SWPPP and implementation of a site-specific SWPPP and associated erosion control, runoff reduction, and sediment removal BMPs (see Table 4.1.2-2), these effects would be minimized and off-site transport of stormwater runoff would be unlikely unless during extreme weather events (i.e., typhoons). Specifically, the site-specific SWPPP would identify appropriate BMPs for the site that would serve to contain runoff and sediment on-site by reducing the flow rate of runoff and thereby minimize transport of suspended sediment through settling and promote infiltration of runoff.

Surface Water

No buildings/structures would be constructed in the 100-year flood zone and the proposed KD Rifle Range located in the 500-year flood zone (see Figure 5.1.2-1) would be in compliance with EO 11988 as the construction would not be categorized as a “critical action.” No surface waters are located within or near the proposed construction areas under Alternative 1. Given compliance with the Construction General Permit and implementation of a Program SWPPP and site-specific SWPPP, off-site transport of stormwater runoff, sediment, or other pollutants would be unlikely. Therefore, construction activities associated with Alternative 1 would result in no direct or indirect short-term impacts to surface water.

Groundwater

Construction activities under Alternative 1 would include stormwater runoff protection measures that would also serve to protect groundwater quality. By adhering to the provisions of the Construction General Permit and implementing BMPs associated with addressing site- and activity-specific water resource protection requirements, there would be a reduction in stormwater pollutant loading potential and thus a reduction in pollution loading potential to the underlying groundwater basins of the NGLA. As described under Alternative A, an environmental and hydrogeologic assessment for the selected alternative would be performed for sinkholes within the project development footprint to ensure adverse
effects to groundwater resources would not occur. Given stormwater runoff protection measures (i.e., compliance with Construction General Permit requirements and implementation of BMPs) and the environmental and hydrogeologic assessment for sinkhole protection (if encroachment is unavoidable), construction activities associated with Alternative 1 would result in less than significant direct or indirect short-term impacts to groundwater.

Nearshore Waters

The Route 15 and HG Range project areas would be located approximately 0.2 mile (0.3 km) and 1.3 miles (2.1 km), respectively, from nearshore waters (see Figure 5.1.2-1). Given compliance with the Construction General Permit and implementation of a Program SWPPP and site-specific SWPPP, off-site transport of stormwater runoff, sediment, or other pollutants would be unlikely (see discussion of BMPs under Construction). In addition, vegetative cover between the construction area and the edge of the steep cliffline and the shoreline would provide an additional buffer and protection from stormwater runoff or sediment reaching nearshore waters. Given adherence to the provisions of the Construction General Permit and implementation of BMPs, it is expected that stormwater runoff, sediment, or other pollutants would not discharge to nearshore waters. Therefore, construction activities associated with Alternative 1 would result in no direct or indirect impacts to nearshore waters.

Wetlands

No wetlands are located in or near the construction areas associated with Alternative 1. Therefore, construction activities associated with Alternative 1 would result in no impacts to wetlands.

Operation

Alternative 1 would incorporate the concept of LID in the final planning, design, and construction of the stormwater management system as described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.1: North, pages 4-85 to 4-87) and under Alternative A in Section 4.1.2.2 of this SEIS. Stormwater runoff associated with the operational phase of Alternative 1 would be similar as described under the Route 15 option in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.2: Central, page 4-97). Minimal increases in stormwater runoff from increased impervious area would be accommodated through the implementation of LID measures and BMPs. Alternative 1 would potentially increase the amount of POLs, hazardous waste, herbicides, pesticides, and fertilizers being stored, transported, and utilized on the proposed facilities. However, impacts from these contaminants would be minimized with the implementation of a SWPPP, SWMP, and SPCC plan.

Alternative 1 would include implementation of the REVA program and range management preventative measures (i.e., vegetation, pH adjustment, LID). The REVA program utilizes available site-specific data and actual munitions loading data to determine further assessments regarding the potential for an identified receptor to be impacted by potential munition constituent migration through an identified pathway (see Section 5.5.1.2, Operation). As listed in Section 2.8 of this SEIS, the BMPs would reduce the potential for contaminants to migrate off-site. In addition, DoD would investigate additional technologies that could assist with range design and management to minimize potential impacts. Baseline data on water quality and range site conditions would be collected prior to range construction and quarterly monitoring would occur during operations to verify the effectiveness of BMPs. For each range, water quality treatment strategies would be selected to achieve reductions of non-point source pollutants to meet the same water quality requirements as identified under Alternative A in Section 4.1.2.2 of this SEIS.
Surface Water

No surface waters are located within the Alternative 1 project area and the implementation of an appropriate and comprehensive stormwater management plan utilizing a LID approach and range management BMPs would ensure that there would be no increase in off-site transport of excess stormwater runoff, sediment, or other pollutants for up to the 25-year design storm event. Therefore, implementation of Alternative 1 would result in no impacts to surface water.

Groundwater

Potential impacts to groundwater associated with the operational phase of Alternative 1 would be similar to those described under the Route 15 option in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.2: Central, pages 4-97 to 4-98) and summarized in Chapter 2 of this SEIS. Range operations under Alternative 1 have the potential to leach MCs to the groundwater. However, range management BMPs would be implemented, as listed in Section 2.8 of this SEIS. As indicated in the 2010 Final EIS, the Route 15 project area overlies the Mangilao Basin and a small portion of the Yigo Basin of the NGLA. Because the NGLA is used as a source for drinking water, prior to the construction of the ranges, both a site inspection and a site assessment, as well as actual munitions loading data, would be provided to the Marine Corps’ REVA and ORC programs. These programs would use the site specific data to determine the appropriate frequency of monitoring and range clearance.

Under the REVA Program, site specific data would be used to evaluate the potential for MCs to reach potential receptors. This would allow the REVA program to determine whether follow-on actions would be required (e.g., sampling, additional studies) and the frequency of any further evaluations. The REVA assessment would use conservative assumptions and available site specific information to determine if modeling can be performed for lead components. Monitoring of the ranges for MCs migrating off-range would be based on the outcome of the REVA assessment. REVA assessments would begin in the first year of operation and would then be conducted at a minimum every 5 years.

The ORC program would not only consider the site-specific and REVA data but also safety and sustainability considerations in its assessment to determine the required frequency of range clearance.

Munitions constituents associated with small arms ammunition commonly used at operational ranges include lead, antimony, copper, and zinc. Lead is the primary munitions constituent indicator for small arms ranges because lead is the most prevalent (by weight) constituent associated with small arms ammunition. No specific quantitative conclusions can be made regarding the fate and transport of lead, because lead is geochemically specific regarding its mobility in the environment. Site-specific conditions are required (i.e., geochemical properties) in order to quantitatively assess lead migration. Site-specific geochemical properties are only identified via sampling and cannot be observed physically. Without site-specific physical and chemical characterization, lead cannot effectively be modeled using fate and transport modeling. The scientific community has established that metallic lead (such as recently fired, un-weathered bullets and shot) generally has low chemical reactivity and low solubility in water and is relatively inactive in the environment under most ambient or everyday conditions. However, a portion of lead deposited on a range may become environmentally active if the right combination of conditions exists.
As indicated in the above paragraphs, a site inspection and site assessment will be completed at the range and the site-specific information provided to the REVA Manager. The REVA manager will utilize this site-specific information in their assessments of the range, which begin the first year of range operation. Assessing small arms ranges first involves defining and documenting its physical and environmental conditions, as well as how the range is utilized and maintained. The assessment process involves a review of possible factors that can influence the potential for lead to migrate off range including range use and management (source), surface water, groundwater and soil conditions, pathways and receptors (including but not limited to people, sensitive and endangered species). Upon review, if factors or a combination of factors are found to exist that would indicate possible lead migration, REVA program managers consider sampling appropriate media, identifying and implementing BMPs adjustments or taking other steps as required.

Quarterly inspections of the range BMPs will also be performed. Inspections will lead to identifying if BMPs are still in place or if maintenance is required. Any deficiencies that cannot be immediately addressed will be reported to the Public Works Department for corrective action. Additionally, the REVA program will also evaluate BMP effectiveness and recommend adjustments as needed.

The DON will investigate additional technologies that could assist with range design and minimizing potential impacts (specific technologies or brands were not mentioned to ensure the full range of BMPs are considered). Prior to the construction of the range, the DON will perform a site survey/inspection to inform range design activities, to include evaluating the optimal site grading and any necessary soil amendments to minimize range constituent migration. Appropriate BMPs will be evaluated and incorporated into the design and construction of the range to minimize the off-site migration of stormwater runoff and reduce the infiltration of MCs (e.g. vegetation buffers, pH adjustment of soil and water quality/quantity BMPs). Designs will subsequently be coordinated and approved through Head, Range Design and Safety, Commanding General Marine Corps Combat Development Command.

All proposed ranges under Alternative 1, except for the HG Range at Andersen South and the MPMG Range, would be entirely located to the southwest of the groundwater divide, which places a low permeability barrier (i.e., volcanic basement rock) between the ranges and the Marbo production wells (Figure 5.1.2-2). A portion of the MPMG Range would be located to the west of the groundwater divide and could potentially leach contaminants to the Marbo production wells (Figure 5.1.2-2). However, the potential for contaminants would be primarily at the eastern end of the MPMG Range where the berm area would be located, and therefore isolated from the Marbo production wells by the low permeability barrier. HQMC commissioned a study on the effects of pumping and drought on the NGLA (USGS Scientific Investigations Report 2013-5216: The Effects of Withdrawals and Drought on Groundwater Availability in the Northern Guam Lens Aquifer, Guam). Information from this report will be used to adjust pumping rates in order to avoid increased salinization and reversal of groundwater flow patterns.

Impacts associated with the ranges would be minimized through implementation of the REVA program and range management preventative measures (i.e., vegetation, pH adjustment, LID) listed in Section 2.8 of this SEIS. The HG Range at Andersen South would be located near the Marbo #8 and Marbo #9 wells (Figure 5.1.2-2). However, the HG Range has been sited outside of the 1,000-foot (300-m) wellhead protection zone in accordance with GEPA regulations, and potential impacts to groundwater from contaminants would be minimized through implementation of BMPs listed in Section 2.8 of this SEIS.
Figure 5.1.2-2
Groundwater Wells in the Vicinity of Route 15 LFTRC Alternative 1

Sources: USGS 2003; NAVFAC Pacific 2013
Given the aforementioned BMPs, including the REVA program, and the location of range activities in relation to active and proposed wells, operations associated with Alternative 1 would result in less than significant long-term, direct or indirect impacts to groundwater.

Nearshore Waters

Under Alternative 1, proposed operations would be in compliance with the stormwater runoff protection measures identified above that would ensure that there would be no increase in off-site transport of stormwater runoff, sediment, or other pollutants to nearshore waters for up to the 25-year design storm event. In addition, vegetative cover between the project area and the edge of the steep cliffline and the shoreline would provide an additional buffer and protection from stormwater runoff or sediment reaching nearshore waters. Therefore, there would be no impacts to nearshore waters from stormwater runoff associated with increased impervious areas and training activities under Alternative 1.

The SDZ associated with the Alternative 1 LFTRC range would overlap nearshore waters by approximately 2,805 acres (1,135 ha) (see Figure 5.1.2-1). There would be a very small chance that an expended projectile would fall outside of the range footprint, within the SDZ. There would be an even smaller chance for an expended projectile to fall within the nearshore water portion of the SDZ. Due to the small number of potential projectiles that could fall into the nearshore SDZ and the relatively small size of the projectiles, potential impacts to nearshore water quality from these projectiles would be negligible under Alternative 1.

Wetlands

No wetlands are located within or near the proposed operational areas under Alternative 1. Therefore, operations associated with Alternative 1 would result in no impacts to wetlands.

5.1.3 Air Quality

5.1.3.1 Affected Environment

Ambient air quality conditions along Route 15 where LFTRC Alternative 1 would be developed are affected primarily by mobile source emissions along Route 15 and aircraft operations at AAFB. The closest main stationary combustion source, Marbo Power Station, is owned by the GPA and located approximately 2 miles (3.2 km) due west of the proposed LFTRC, and would also affect air quality conditions in the neighborhood around the proposed site. Table 5.1.3-1 shows the permitted emissions from Marbo Power Station. Sensitive populations near the site are relatively small in size, and are scattered along those major routes, such as Route 15.

5.1.3.2 Environmental Consequences

Construction

Annual Emissions

Direct emissions of criteria pollutants and CO\textsubscript{2} from operations of on-site equipment and construction vehicles were estimated based on the acreage of disturbed earth and the number and type of facilities to be constructed within the 2-year duration of the overall construction period. The direct emissions are summarized in Table 5.1.3-2 and are predicted to be well below the significance criterion of 250 tpy. This comparison evaluation is further elaborated in Chapter 6, by combining both cantonment/family housing and Alternative 1 elements in terms of annual emissions with comparison of the 250 tpy threshold. A similar GHG emissions comparison is also included in Chapter 6.

On-Site Equipment and Vehicle PM Hot-Spot Analysis

Under Alternative 1, the annual on-site PM emission levels predicted and summarized in Table 5.1.3-2 are much less than under Alternative A (see Table 4.1.3-2 in Chapter 4 of this SEIS; i.e., 0.4 tpy as compared to 2.8 tpy for PM\textsubscript{10} under Alternative A) for which a hot-spot impact modeling was conducted. Therefore, the on-site hot-spot PM impacts from equipment and vehicle operations around construction sites are anticipated to be much less than those under Alternative A, as shown in Table 4.1.3-3 in Chapter 4 of this SEIS.

Off-Site On-Road Vehicle Hot-Spot Analysis for PM

As described in Section 4.1.3, under the worst-case alternative; the future worst-case construction year annual average daily traffic of the roadways within the study area are well below the USEPA defined screening threshold of 125,000 annual average daily traffic and 8% diesel truck traffic, which equates to 10,000 trucks. A further hot-spot dispersion modeling analysis using AERMOD or CAL3QHCR is not warranted, and there would be no PM hot-spot concerns along the affected roadway network. Because the diesel truck component under Alternative 1 would be much less than those under Alternative A, there would no PM hot-spot concerns.

Off-Site On-Road Vehicle Hot-Spot Analysis for CO and MSATs

The construction associated with on-road truck activities under Alternative 1 would occur along the same truck routes available for all alternatives. The detailed hot-spot impact analysis was conducted for the worst-case condition under the Alternative A, as discussed in Sections 3.3.3 and 4.1.3, and the analysis concludes that the direct, short-term impacts under Alternative A would be less than significant. Because the truck activities associated with Alternative 1 would be much less than those under Alternative A, the off-site, on-road vehicle hot-spot impacts are anticipated to be much less than those under Alternative A, as shown in Tables 4.1.3-4 for CO, 4.1.3-5, 4.1.3-6 for carcinogenic MSATs, and 4.1.3-7 for non-carcinogenic MSATs.
**Operation**

The hot-spot impact analyses of on-road vehicle CO, PM, and MSATs emissions during operational years were conducted for both the preferred and worst-case alternatives (i.e., Alternative A and Alternative D), as discussed in Sections 4.1.3 and 4.4.3, and show less than significant long-term impacts. Because the on-road traffic with potential to be generated under Alternative 1 would be substantially less than either Alternative A or Alternative D, the anticipated on-road hot-spot impacts during operational years would be much less than those under Alternative A or Alternative D; resulting in less than significant direct, long-term hot-spot air quality impacts.

Based on these findings, Alternative 1 would result in less than significant short- and long-term direct or indirect air quality impacts during both construction and operational phases.

5.1.4 Noise

5.1.4.1 Affected Environment

As stated in the 2010 Final EIS (Volume 2, Chapter 6: Noise, Section 6.1.3: Central, pages 6-13 and 6-17), basic non-live fire ground maneuver training in the Alternative 1 area occurs on Andersen South. These activities include routine training exercises, camp/tent setup, survival skills, land navigation, day/night tactical maneuvers and patrols, blank munitions and pyrotechnics firing, treatment and evaluation of casualties, fire safety, weapons security training, perimeter defense/security, and field equipment training. Vacant single-family housing and vacant dormitories are used for military operations on urban terrain training and small-unit tactics in support of vehicle and foot-based maneuver training. Noise-generating activities associated with this training include vehicle use, use of breacher charges and pyrotechnics, and small arms firing. Although residential land use occurs along the Andersen South boundary, there are no noise issues as these operations are conducted at interior locations of the installation, away from the Alternative D site boundary.

Noise levels from aircraft operations at AAFB near the Route 15 lands currently range below 65 dB and a finger of the 60 dB contour extends just to the north of the Guam International Raceway as shown on Figure 4.1.4-1.

In addition, on the Route 15 lands, noise is generated from activities at Guam International Raceway, which is Guam's only automobile raceway. The 250-acre (101-ha) parcel includes a 14 mile (23 km) dirt track, a 0.5 mile (0.8 km) asphalt NASCAR type track, a 1 mile (1.6 km) long off-road course, and a paved 2.25 mile (3.6 km) Formula Three track. Racing events at Guam International Raceway generate noise from racing vehicles and crowd activity.

People living in areas adjacent to the Route 15 lands experience exposure to elevated noise due to the limited military training on Andersen South and Guam International Raceway events. While these noise levels have not been quantified, they are intermittent and return to ambient noise levels upon completion of the noise events. During inactive times at Andersen South and the Raceway, ambient noise levels equate to approximately 50-60 dB (USEPA 1978).

5.1.4.2 Environmental Consequences

**Construction**

Noise generated during LFTRC construction with the potential to affect sensitive receptors would be due to grading and construction activities at the firing lines and at the range operations facilities located closest to the nearest receptors. Grader and scraper noise would be approximately 67 dB at the nearest
receptor. Construction would be short-term and noise would not exceed construction noise level standards and guidelines. Direct, short-term noise impacts are considered less than significant.

Operation

The main source of noise associated with Alternative D would be small arms training at the proposed range complex. Small arms to be fired at these ranges would include the 9 mm pistol, the .45 caliber pistol, the 5.56 mm rifle, the 7.62 mm machine gun, and the .50 caliber machine gun. Because it is an inert training round, the 40 mm MK 19 TP that would be authorized for use at the machine gun multipurpose range was also assessed as small arms munitions. Under this alternative, existing noise generated by Guam International Raceway activities would no longer occur as the facility would no longer operate in this area.

The estimated average annual number of rounds for each type of live-fire training event for both Marine Corps and Joint Use operations is provided in Chapter 2, Table 2.2-4 of this SEIS. Marine Corps daytime usage would total approximately 4,275,000 rounds and night usage would be approximately 1,063,000 rounds. Night firing training requirements need to be met during hours of darkness, dusk until dawn, and this timeframe differs from “acoustic” night (10 p.m. to 7 a.m.). Of the 1,063,000 rounds expected to be fired during darkness, only 326,000 rounds or 7% of the total number of rounds would occur during “acoustic” night and no training is planned to occur between the hours of 10:00 p.m. and 6:00 a.m.

There are two major noise sources generated from small arms munitions firing. The first is the muzzle blast from the firing of a bullet. The second is the noise from the bow shock wave (also known as ballistic wave) generated by the supersonic bullet. The bow shock wave propagates out from the path of the bullet. The bullet from an M16 has an exit velocity of approximately 3,100 feet (945 m) per second, but decelerates quickly.

Firing noise from single shots merged in bursts, machine gun burst, and concurrent firing of multiple weapons, as would occur at the proposed ranges, would result in short periods of intense firing noise followed by longer periods of silence. There is increased annoyance associated with this noise exposure pattern. Under these conditions, the number of shots becomes more important than the dB level of the typical (average) shot because of the combined effect of greater noise levels of multiple noise events occurring over a short period.

The results of the Alternative 1 noise modeling (Army 2013) are shown in Figure 5.1.4-1. Under this alternative, the Zone 2 noise contours cover approximately 130 onshore acres (53 ha) beyond the boundaries of Route 15 lands and Zone 3 affects about 3 acres (1 ha). Offshore, Zone 2 would cover approximately 577 acres (233 ha) but no Zone 3 contours extend offshore. The estimated population affected by Zone 2 would be 88 people, and no persons would be affected in Zone 3. Table 5.1.4-1 lists the Noise Zones and the associated acreage affected within each zone. Noise generated by Joint Service users at the LFTRC would fall within the contours shown because the noise contours were calculated as an average busy day and the use by other services would be more infrequent and less intense than Marine Corps usage.

Notes: ^1 Zone 1 is not listed because all land uses are compatible within Zone 1.  
^2 Based upon four persons per household in Yigo (GBSP 2010).  

In addition to the LFTRC, a HG Range would be located in the central part of Andersen South. This range would be common to all proposed LFTRC alternatives. The proposed HG Range would include an approximately 0.9 acre (0.4 ha) area that would be developed as a training facility for the M67 fragmentation hand grenade. It would consist of a demonstration area with bleachers, an open practice throwing field with various targets and throwing positions located outside the hazard zone, and a parking area. A 1.0 acre (0.4 ha) training area would be developed adjacent to the range (additional details pertaining to the proposed HG Range are provided in Chapter 2, Section 2.2.3 of this SEIS).

The HG Range noise contours would generate a Land Use Planning Zone covering approximately 213 acres (86 ha), about 128 acres (52 ha) in Zone 2, and about 26 acres (11 ha) in Zone 3. However, all of the acreage affected by HG Range noise contours remains within Andersen South and no people would be affected by this noise. Hand grenades generate blast noise and are expressed as C-weighted noise levels. Figure 5.1.4-2 shows the Noise Zones around the HG Range in Andersen South and Table 5.1.4-2 lists the associated acreage affected within each zone.

Source: NAVFAC Pacific 2013
Under this alternative, an estimated 22 homes and 88 people would be directly impacted by Zone 2 noise levels. Residential land use in Noise Zone 2 is normally considered incompatible unless mitigation can be implemented to reduce noise levels inside homes. Because there would be additional people exposed to incompatible noise levels and because the estimated noise would conflict with Marine Corps land use planning guidance for residential areas, these direct, long-term impacts would be considered significant. Other direct noise impacts, such as potential hearing loss, would not occur because maximum ADNL is below 75 dB ADNL. Indirect impacts due to noise such as decreases in job performance and inauditory health effects are widely debated but there are no unambiguous studies indicating that performance and inauditory health effects would occur below maximum ADNL levels of less than 75 dB (Department of Defense Noise Working Group 2009). Potential mitigation measures to reduce noise impacts include maintaining/enhancing dense foliage and/or constructing berms between the range and the residences. Doing so has the potential to decrease noise levels by 6 dB, thereby mitigating impacts to most of the residences to less than significant (U.S. Army Center for Health Promotion and Preventive Medicine 2010). If this alternative is chosen for implementation, a detailed noise reduction plan would be developed to reduce impacts to below significant levels.

Alternative 1 is the only proposed LFTRC alternative that would result in potentially significant impacts. However, these impacts could potentially be mitigated to less than significant through the use of berms and natural foliage, as described above.

5.1.5 Airspace

5.1.5.1 Affected Environment

Guam Air Route Traffic Control Center

The current airspace structure for Guam is covered by the Guam ARTCC. The Guam ARTCC is one of 22 FAA en route air traffic control facilities in the U.S. and its territories, and it serves a large area that is part of the Oakland Center Flight Information Region. Guam ARTCC airspace is essentially a 250-nautical mile (463 km) circle with Guam at its center, and is based on the radar coverage available from the radar site on Mount Santa Rosa, Guam.

The existing airspace structure for Guam consists of Class D, Class E, SUA and ATCAAs. Class D airspace is associated with AAFB and Guam International Airport. It includes the airspace within a 4.3-nautical mile (8 km) radius around each airfield and extends from the surface to 2,600 feet (792 m) MSL.

Class E airspace encompasses all other undesignated airspace. Class E airspace extends upward from either the surface or a designated altitude to the overlying or adjacent controlled airspace. If an aircraft is flying on a federal airway below flight level (FL) 180 (18,000 feet [5,486 m] MSL), it is in Class E airspace. Class E airspace is also the airspace used by aircraft transiting to and from the terminal (e.g., an airport) or en route beginning from 14,500 feet (4,420 m) AGL to FL180. Class E airspace ensures IFR aircraft remain in controlled airspace when approaching aircraft outside Class D airspace or when flying on “Victor Airways,” which are federal airways below 18,000 feet (5,486 m) MSL. VFR aircraft can fly up to 17,500 feet (5,334 m) AGL if they can maintain VFR weather clearance criteria and the aircraft is equipped to fly at 17,500 feet (5,334 m) AGL.

The Guam ARTCC facility and the FAA regional offices are situated at Guam International Airport. The major airfields on Guam (i.e., Guam International Airport and AAFB) are within 10 nautical miles (18.5 km) of each other. The Guam ARTCC provides approach and departure services for airports within
Guam ARTCC airspace and control of aircraft flying through ARTCC airspace. Radio aids to navigation on Guam include one VHF Omni directional Radio Range-Tactical Air Navigation (Nimitz), one at AAFB, and two non-directional beacons (Mount Macajna and Rota). Rota International Airport, Tinian International Airport, and Saipan International Airport, all within 130 miles (209 km) of Guam, serve as suitable alternate airports for aircraft bound for Guam International Airport or AAFB.

Guam International Airport

Guam International Airport is the only civilian air transportation facility on Guam. The airport’s two parallel runways are oriented northeast to southwest. Runway (RWY) A24 left (RWY 24L) and 06 right (RWY 06R) and Runway 24 right (RWY 24R) and 06 left (RWY 06L) are 10,015 feet (3,053 m) and 10,015 feet (3,052 m) in length, respectively. Guam International Airport has Class D airspace (Figure 5.1.5-1), and has continuous operations (i.e., 24 hours per day). The Class D airspace extends from the surface upward to and including 2,600 feet (792 m) MSL within a 4.3 nautical miles (7.9 km) radius of Guam International Airport. Based on the 10 nautical miles (19 km) distance between Guam International Airport and AAFB, there is approximately 1 nautical mile (1.9 km) of separation between the Class D airspace associated with each airport.

Detailed information on civilian air traffic associated with Guam International Airport is provided in the 2010 Final EIS (Volume 2, Chapter 7: Airspace, Section 7.1.3: Civilian Air Traffic, pages 7-10 to 7-11).

Andersen Air Force Base

Andersen Tower’s Class D Airspace is within a 4.3 nautical miles (7.9 km) radius of the Airport Reference Point (1335.04N/14455.80E) of AAFB, from the surface up to and including 2,600 feet (792 m) MSL (see Figure 5.1.5-1). Andersen Tower and Airfield Management Operations is open 24 hours a day, 365 days a year.

AAFB contains two airfields: one main, base-proper airfield (North Field) and NWF airfield. Airspace over AAFB North Field supports flight operations including takeoffs, landings and traffic pattern training of all types of aircraft up to and including B-52s, C-5s, C-17s, MH-60s, and KC-135s. There are eight instrument procedures supporting AAFB: ILS OR LOC/DME RWY 24L, ILS OR LOC/DME RWY 24R, ILS OR LOC/DME RWY 06L, ILS OR LOC/DME RWY 06R, TACAN RWY 06L, TACAN RWY 06R, TACAN RWY 24L, and TACAN RWY 24R. Detailed information on military air traffic associated with AAFB is provided in the 2010 Final EIS (Volume 2, Chapter 7: Airspace, Section 7.1.2: Military Air Traffic, pages 7-8 to 7-10).

Source: NAVFAC Pacific 2013
Military Aviation Training Areas

Existing SUA in the region consists of W-517 and R-7201 (Figure 5.1.5-2). W-517 is a Warning Area that overlays deep ocean water located approximately 50 miles (80 km) south-southwest of Guam and is constrained by high altitude jet routes converging over Guam that run to the east and west of the Warning Area. R-7201 is the Restricted Area surrounding Farallon de Medinilla (3-nautical mile [5.6-km] radius) with altitudes from the surface to unlimited and encompasses 28 square nautical miles (96 square km).

A Restricted Area is a type of SUA that is identified as an area within which the flight of aircraft, while not wholly prohibited, is subject to restrictions. Activities within Restricted Areas must be confined because of their nature or limitations imposed upon aircraft operations that are not a part of those activities, or both. Restricted Areas denote the existence of unusual hazards to aircraft such as artillery firing, aerial gunnery, small arms fire, or guided missiles. Penetration of Restricted Areas without authorization from the using or controlling agency may be extremely hazardous to the aircraft and its occupants. A Warning Area is airspace of defined dimensions, extending 3.0 nautical miles (5.5 km) outward from the shoreline that contains activity that may be hazardous to nonparticipating aircraft. The purpose of such Warning Areas is to warn nonparticipating pilots of the potential danger. A Warning Area may be located over domestic or international waters or both.

ATCAA is airspace of defined vertical and lateral limits assigned by the FAA. ATCAA areas are established for the purpose of providing air traffic segregation between the specified activities being conducted within the assigned airspace and other IFR air traffic. There are open ocean ATCAAs within the Guam and CNMI region used for military training activities, from unit level training to major joint exercises. ATCAAs 1, 2, 3, 5, and 6 as depicted in Figure 5.1.5-2 have been pre-assigned in agreements with Guam ARTCC, COMNAV Marianas, and the Commander, 36th Wing, AAFB.

The ATCAAs are activated for short periods to cover the timeframes of training activities. ATCAA-6 overlies Guam and has an altitude structure of FL 390-430. Data available from FY 2009 indicate that ATCAA 6 was used a total of 381 hours over 61 days by a mix of aircraft including B-52, KC-130, KC-135, and B-2. This usage is based on a long-term agreement that is still in effect and would not substantially change over time.

A Controlled Firing Area (CFA) is airspace designated to contain activities that if not conducted in a controlled environment could be hazardous to nonparticipating aircraft. CFAs provide a means to accommodate certain hazardous activities that can be immediately suspended if a nonparticipating aircraft were to approach the area.

5.1.5.2 Environmental Consequences

Construction

No changes to airspace would be required during construction of the LFTRC under Alternative 1, and construction activities would not be expected to conflict or interfere with the use or management of existing airspace in the vicinity. Therefore, construction of the LFTRC under Alternative 1 would have no impact on airspace.
Figure 5.1.5-2
Existing SUA within Guam ARTCC Airspace

Source: NAVFAC Pacific 2013
Operation

Figure 5.1.5-3 depicts the proposed Restricted Area associated with the Alternative 1. This SUA would be needed to contain the vertical hazard associated with the proposed live-fire training. Boundary coordinates for the proposed Andersen South/Plateau Primary Option of R-7202 Guam would begin at:

- lat.13°31'28"N., long.144°53'6"E
- to lat.13°29'47"N., long.144°55'55"E
- to lat.13°28'3"N., long.144°55'0"E
- to lat.13°28'48"N., long.144°53'5"E
- to lat.13°29'48"N., long.144°52'15"E
- to the point of beginning

Altitudes for this Restricted Area SUA would be from the surface to 3,000 feet (914 m) above ground level. Activation of proposed R-7202 would occur when live-fire includes weapons with vertical hazard values, which may pose a threat to non-participating aircraft. Live-fire training is estimated to occur 39 weeks per year. Times of use would typically be between 6:00 a.m. and 7:00 p.m. local time. On average, the planned use of the airspace would fall within the charted “times of use.” However, a DoD requirement exists for planned live-fire range use during hours of darkness. As a result, it is anticipated that a minimum of 15% of the range use would be outside of typical daily times. Night training is estimated to occur twice per week during the qualification periods and would require consecutive firing days.

The Controlling Agency for the proposed R-7202 would be FAA Guam and the Using Agency would be Commander, Joint Region Marianas.

In addition to the LFTRC, an HG Range would be located at Andersen South. This range would be common to all LFTRC alternatives. Figure 5.1.5-4 depicts the proposed CFA associated with the use of the HG Range at Andersen South for all LFTRC alternatives. Activities conducted within the proposed CFA may include live-fire HG employment to include basic employment and safe operation, as well as employment of HG in an urban environment. The times of use for the proposed CFA would be 7:00 a.m. to 12:00 p.m. local time, 2 to 3 times per week. Similar to the proposed R-7202, the Controlling Agency for the proposed CFA would be FAA Guam and the Using Agency would be Commander, Joint Region Marianas. Safety procedures would be implemented to ensure the safety of civilian aviation. Such procedures would include, but would not be limited to, posting range regulations with detailed operating procedures, and real-time communications with air traffic control and range clearance personnel.

Section 3.5.3.1 identifies the potential impacts to airspace from implementation of the LFTRC alternatives. The FAA stated in the preliminary Airspace Feasibility Assessment (FAA 2013) that Alternative 1, while not preferred, is feasible with the appropriate mitigation.

Operational activities under Alternative 1 have the potential for significant direct impacts to aviation due to the following:

- Guam International Airport airspace and instrument approach procedures.
- IFR/VFR traffic flows and terminal operations.
- Known but uncharted high volume routes.
- Existing SUA/Terminal Radar Service Area.
- VFR Reporting Points.
Figure 5.1.5-3
Proposed SUA Associated with LFTRC Alternative 1

Source: NAVFAC Pacific 2013
Figure 5.1.5-4
Hand Grenade Range Proposed Controlled Firing Area Common to All LFTRC Alternatives

Source: NAVFAC Pacific 2013
However, if this alternative is selected, long-term impacts and potential mitigation would be further studied through the DON/FAA/Air Force consultation process. The general types of potential mitigation measures that could be employed may include adjusting airspace through FAA coordination. However, no specific potential mitigation measures are proposed at this time.

As detailed in Table 5.7-1, operational impacts under Alternative 1 would be the same as under Alternatives 2, 3, and 4. Operational impacts under this Alternative would be greater than impacts under Alternative 5.

5.1.6 Land and Submerged Land Use

5.1.6.1 Affected Environment

Andersen South land ownership and land use is as described in the 2010 Final EIS (Volume 2, Chapter 8: Land and Submerged Land Use, Section 8.1.3.1, Andersen South, pages 8-32 to 8-34) and shown on Figure 5.1.6-1. The Route 15 LFTRC alternative affected environment is similar to the 2010 Final EIS Route 15 Range Alternative A. It would include the southeast portion of Andersen South (federally owned), the realignment of a segment of Route 15 (GovGuam-owned) to the interior of Andersen South and the federal acquisition of GovGuam land (Figure 5.1.6-1). The SDZs would extend into the Pacific Ocean and GovGuam submerged lands (Figure 5.1.6-1). All proposed LFTRC alternatives include a HG Range within Andersen South (Figure 5.1.6-1).

The current land use at Andersen South is generally vacant and naturally vegetated. There is vacant housing that has been used for military operations on urban terrain training. In addition, there is a water pump station and five wells with well protection areas, as shown on Figure 5.1.6-1. The planned land use for Andersen South, as described in the 2010 Final EIS, is non-live fire training. The land use adjacent to Andersen South and closest to the HG Range is Residential (based on a review of aerial photographs), and the planned land use is Very Low Density Residential (Figure 5.1.6-1).

The land proposed for acquisition is undeveloped and in its natural state, except for the following land uses: Guam International Raceway, quarry (Hawaiian Rock), pre-development site clearing, and roads. Less than 1% of the area is used for subsistence farming (Appendix D, SIAS, Table 5.3-1, Figure 5.3-3). No residences were identified within the land acquisition area. Planned land use for the acquisition area is primarily Park/Open Space with a small area of Residential in the southwest, and Very Low Residential northwest of Route 15 and Guam International Raceway (Figure 5.1.6-1).

The land adjacent and south of Route 15 was identified by USDA and the Guam Department of Agriculture as important farmland (see Figure 3.6.1-2 in Chapter 3 of this SEIS, and Figure 5.1.6-1), but the more recent land use plans do not identify future agricultural use in the area.

Land uses adjacent to the proposed Route 15 LFTRC include the planned non-live fire training to the west at Andersen South and submerged lands to the east. Pacific International operates a quarry north of the land acquisition area and east of Route 15. A residential community is located north of the International Raceway Park and Route 15. Vacant lands are adjacent to the northeast and southwest of the proposed land acquisition area (Figure 5.1.6-1).
Figure 5.1.6-1
Land Use in the Vicinity of Route 15 LFTRC Alternative 1
The Pågat Trail is aligned along the southwestern edge and outside of the acquisition area. Pågat Cave and Pågat Village are located outside the acquisition area on the coast. Residential land use was identified west of the Pågat Trail and south of Andersen South. Planned land use for the vicinity of the land acquisition area is Very Low Residential to the north, and Park/Open Space and Residential to the northeast and southwest (see Figure 5.1.6-1). Sasayan Valley is located southwest of the acquisition area.

The utility infrastructure improvements for potable water, wastewater, electrical and IT/COMM (on-site) would be within the proposed land acquisition area or existing federal lands. No new easements would be acquired.

5.1.6.2 Environmental Consequences

Land use impacts are addressed in this section. Land ownership impacts are addressed in Section 5.1.15, Socioeconomics and General Services.

Construction

As previously discussed in Chapter 3, Section 3.6.3.1 of this SEIS, all changes in land use are considered long-term operational impacts. Therefore, there is no construction-phase analysis for this resource under any of the alternatives.

Operation

The HG Range (common to all LFTRC Alternatives) would be located entirely within Andersen South. The hand grenade noise assessment methodology and predicted noise contour is presented in Section 5.1.4. Hand grenade noise is unique among the live-fire ranges in that it is characterized by CDNL and not ADNL. Noise Zone 2 (62-70 dB CDNL) is considered incompatible (subject to local zoning) with sensitive land uses (e.g., housing, schools, medical facilities). The nearest sensitive receptors are adjacent and north of Andersen South. The Noise Zone 2 contour lies within the Andersen South boundary and no impact on land use beyond the installation boundary is anticipated.

Any land use incompatibility issues related to the military mission within Andersen South would be resolved through application of installation master planning guidelines outlined in UFC 2-100-01. Therefore, land use impacts on Andersen South would be less than significant.

As described in Chapter 3, Section 3.6.3 of this SEIS, new access restrictions placed on non-DoD populations is a potentially significant adverse impact when access to or existence of a specific community-valued land or submerged land use would be affected. Guam International Raceway is a land use that is unique on Guam and valued in the community for recreational and socioeconomic reasons, as described in Sections 5.1.7 and 5.1.15, respectively. Because implementation of Alternative 1 would result in the direct loss of this raceway, there would be a short- and long-term adverse significant land use impact. The Chamorro Land Trust Commission (CLTC) license that allows the raceway to operate at the present location expires in 2018. Because it is unknown if the license would be renewed irrespective of the proposed action, no potential mitigation measures have been identified to offset the significant land use impact of implementing Alternative 1. In addition, Hawaiian Rock operates a quarry within the proposed LFTRC that would be precluded by the proposed action. The land lease would be terminated and there would be a significant impact on current land use.

There would be no land use impact on the Pacific International quarry, which is located outside of the LFTRC boundary (see Figure 5.1.6-1). With respect to agricultural land use, no USDA-designated prime farmland would be affected. Less than 1.5% of the USDA-designated important farmland would be impacted. The direct, long-term impact to farming would be less than significant because the planned land
use for the acquisition area does not include agricultural land uses. The major planned land use for the area is Park/Open Space, and most of the area would be maintained as open space.

There would be a direct, short- and long-term significant impact associated with new restrictions on public access to the coastal and submerged lands encumbered by the SDZs generated by LFTRC operations. Pågat Village, Cave, and Trail would not be impacted by this alternative. However, SDZs would extend over the Pågat Point cultural site, and public access would be restricted. Access to the submerged lands would be restricted when the ranges are in use, which may interfere directly with recreational activities or indirectly by altering the transit route to recreational sites. This would be a short- and long-term significant impact on submerged land use. The access restrictions would not impact the access to the two Fish Aggregating Devices located east of Guam (see Figure 3.6.1-1). The DoD would consider requests for access for special events (e.g., fishing tournaments) on a case by case basis.

Sensitive land uses are not recommended in Zone 3 (75-85 ADNL) noise contours. Zone 2 (65-74 ADNL) noise levels generated by the proposed LFTRC, excluding the HG Range at Andersen South, are considered incompatible (subject to local zoning) with sensitive land uses and are more suitable for industrial or agricultural uses. As shown on Figure 5.1.4-1 of Section 5.1.4, Noise, the Zone 3 noise contour would extend slightly beyond the proposed northern installation boundary into land that does not include residences. The Zone 2 noise contour for the LFTRC (excluding the HG Range) would also extend beyond the new range boundary into the civilian community. North of the proposed LFTRC there are existing residences within the Zone 2 contour (see Table 5.1.4-1), and the planned land use is Residential and Very Low Residential. Southwest of the proposed LFTRC is vacant land, but the planned land use includes Residential within the Zone 2 contour. The LFTRC noise levels would be incompatible with current and future land use beyond installation boundaries within the Zone 2 and 3 contours and is considered a long-term significant impact on land use. Potential mitigation for minimizing the direct impacts on noise levels are described in Section 5.1.4, Noise. Potential mitigation for land use incompatibilities may include regular DoD coordination with GovGuam on military noise and hazard area information derived from Joint Land Use Studies or Range/AICUZ plans or other studies. These studies or plans would inform future GovGuam zoning or land use decisions and minimize the potential for incompatible public or private development near military installations. Non-DOD potential mitigation would be the GovGuam updates to future community land use plans to address proposed DoD land uses.

The off-base utility infrastructure improvements would not impact existing or planned land uses because the proposed alignments would be on-base or within existing easements and utility corridors.

The significance of land use impacts resulting from implementation of Alternative 1 would be similar to that of Alternatives 2, 4 and 5; Alternative 3 is the only LFTRC alternative with less than significant land use impacts.

5.1.7 Recreational Resources

5.1.7.1 Affected Environment

A list of recreational resources near Alternative 1 is contained in the 2010 Final EIS (Volume 2, Chapter 9: Recreational Resources, Section 9.1.2.4: Non-Department of Defense Land and Section 9.1.3: Central, pages 9-4 to 9-11). In addition to the listed resources and activities, the area is popular with residents and visitors alike for spelunking and off-trail backcountry hiking activities at Pågat and Marbo Caves and the surrounding areas. Other recreational opportunities within the north region of Guam include trails, historic/cultural attractions, beaches/parks, scenic points, diving locations, and others (e.g., golf courses). These recreational opportunities include public and non-public facilities. Non-public
facilities include those contained within lands identified as military installation. Access and use of these facilities within federal lands is limited to installation personnel and their guests. Public recreational facilities are located on non-federal lands and include marine preserves. Routes 1, 3, 9, and 15 provide regional access to recreation opportunities within the north region. As previously discussed in Sections 5.1.4 and 5.1.6, Guam International Raceway is an important recreational resource. The Raceway is leased from the Chamorro Land Trust. Other notable recreational resources include Pågat Trail, Pågat Point, Pågat Cave and Village, Marbo Cave, Taguan Point Scenic Vista, Taguan Hiking Trail, Lujuna Point, and Lujuna Hiking Trail. Recreational resources within the vicinity of Alternative 1 are identified in Table 5.1.7-1.

Source: DON 2010.

The Pågat Trail, Cave, and Village complex is an area of cultural and historical importance and “the coastal area is also a significant pre-historic site on the NRHP and has other unique geological features such as caves with fresh water” (GCMP 2011). As discussed in Section 3.10.2 of this SEIS, after signing the 2011 PA, the Marine Corps began evaluating options to satisfy the commitment to provide continued access to Pågat Village and Pågat Cave. With this access commitment in mind, the Alternative 1 would be designed to avoid impacting Pågat Village, Cave, and Trail, primarily through the redesigned and reduced footprint for the SDZs, both on land and over water. Lujuna Point and Lujuna Hiking Trail are located on Chamorro Land Trust property (GBSP 2013).

5.1.7.2 Environmental Consequences

As discussed in Section 1.1, ensuring access to Pågat Village and Cave, 24 hours a day, 7 days a week, reflects a formal commitment announced by the Under Secretary of the Navy in January 2011, in addition to being stated in the ROD for the 2010 Final EIS. The revised SDZs avoid direct impacts to Pågat Village, Pågat Cave and Pågat Trail, but still results in the closure of access to the Pågat Point cultural site, which would remain within the redesigned SDZs. And while the trail leading to Pågat Village and Cave would not directly connect with a realigned Route 15 (see Figure 2.5-2, Chapter 2 of this SEIS), the trail would still connect with the old Route 15 that would remain open to the trailhead.

The use of the proposed LFTRC would result in restricted access to some dive spots, fishing zones, and snorkeling areas for the public. Popular dive/snorkeling locations are mainly on the west (leeward) side of the island. Off-shore waters from the Route 15 alternative are generally rough and turbulent and are not ideal conditions for diving or snorkeling. Indirect short-term impacts from firing range noise are not expected to significantly lessen visitor enjoyment of recreational resources in the surrounding terrestrial or marine areas.

Implementation of this alternative would require the closure of Guam International Raceway and the acquisition or leasing of its parcel, resulting in direct, short- and long-term significant impacts to this recreational resource. As discussed in Section 3.7.3.3, the majority of comments received during scoping were related to the possible closure of Guam International Raceway, resulting from the selection of
Alternative 1 and the significant impacts anticipated by the community if that closure were to occur. There are no other raceways of this type on Guam that could be used in the event of the closure of Guam International Raceway.

Construction

Route 15 would be realigned inland to allow for land acquisition to accommodate the proposed range and SDZ configuration. This realignment process would require grading, grubbing, cutting, and filling. Direct, short-term impacts to recreational resources would result during the construction phase, primarily through possible vehicle delays in reaching recreational sites, caused by earth-moving and construction vehicles on Route 15 and peripheral roadways. Although staged construction equipment would not obstruct access to, or use of, recreational resources, short-term inconvenience to resource seekers (e.g., potential detours, longer wait, and other similar inconveniences) would result in direct, short-term less than significant impacts.

In addition to short-term impacts to other recreational resource access during construction, the commencement of the construction phase itself would require the permanent closure of the Guam International Raceway, resulting in a significant direct, long-term impact to this recreational resource.

Operation

While Pågat Village, Cave, and Trail would not be directly impacted by implementation of this alternative, SDZs would still extend over the Pågat Point cultural site and would represent a direct and indirect long-term significant impact to the public’s access to this archeological area during Marine Corps training (see Section 5.1.6.2). Furthermore, this alternative would result in the closure of the Raceway. The loss of the Raceway would be considered a direct and long-term significant impact because this particular use would be discontinued and a similar use is not found elsewhere on Guam. Potential mitigation measures have not been identified to offset the significant impacts to recreational resources with implementation of Alternative 1.

5.1.8 Terrestrial Biological Resources

5.1.8.1 Affected Environment

Vegetation Communities

Figure 5.1.8-1 depicts the vegetation communities within the boundaries of the Route 15 lands and Andersen South. The vegetation communities were mapped based on the following sources:

- USFS (2006) - island-wide coarse-scale mapping used as the starting point.
- Field surveys conducted in 2008 and 2010 in targeted areas for more fine-scale mapping.
- 2011 aerial imagery - review of that imagery showed large areas of vegetation recently cleared near Guam International Raceway.

Vegetation types are described in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.1.1: Vegetation Communities, pages 10-1 to 10-6). The Route 15 LFTRC action area encompasses large areas of primary limestone forest on the upper plateau at cliff edges and on the coastal bench below the cliffline. Some forests on the upper plateau near the cliffline are growing on rugged limestone terrain of sharp pinnacles, towers, and narrow fissures and, as a result, are minimally disturbed by ungulates.
Terrestrial Conservation Areas

The Route 15 LFTRC action area does not contain any designated terrestrial conservation areas.

Wildlife - Native Species

No new information is available for the Route 15 and Andersen South areas since the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Sections 10.1.4.1: Andersen South and 10.1.4.2: Non-DoD Land, pages 10-52 to 10-59). Native wildlife species within the project area include the yellow bittern, blue-tailed skink, and mourning gecko, which are common throughout Guam. Non-native species reported in the 2010 Final EIS include feral pigs, Philippine deer, and various amphibians and reptiles, including the brown tree snake, that are common on Guam.

Special-Status Species: Federal ESA-Listed and Proposed Species

One federal ESA-proposed species (Mariana eight-spot butterfly) occurs within the proposed Route 15 LFTRC alternative (Table 5.1.8-1 and Figure 5.1.8-2). Although “suitable habitat” for special-status species is present within the Alternative 1 project areas, the brown tree snake, the primary factor in the extirpation of special-status wildlife species on Guam and one of the largest obstacles to achieving recovery of special-status species, is still considered abundant and widespread on Guam. Until brown tree snakes are suppressed or removed from at least targeted areas on Guam, the habitat is not in a suitable condition to support the survival of special-status species due to current snake abundance on Guam (e.g., Guam Micronesian kingfisher, Guam rail, Mariana crow) (USFWS 2010a).

Inset 2
Detail - see inset 2
In addition to field surveys conducted in 2009 and 2010 in support of the 2010 Final EIS, field surveys for this SEIS were conducted in 2013 for Mariana fruit bats at Andersen South (Vogt and Farley 2013) and for federal ESA-proposed species at Andersen South and the Route 15 lands (UoG 2014).

**MARIANA FRUIT BAT.** The last recorded sighting in the Route 15 action area was of a single fruit bat in 1999 (Duenas & Associates 2000). Surveys in 2009 at Route 15 (NAVFAC Pacific 2010) and in 2013 at Andersen South (Vogt and Farley 2013) did not detect any bats. The closest known occurrence of fruit bats is on AAFB, more than 6 miles (9.7 km) to the north of the Route 15 LFTRC action area. While fruit bats are known to travel 6-7.5 miles (10-12 km) to reach forage areas (USFWS 1990, 2009a), and the cliffline along the Route 15 lands contains suitable fruit bat habitat, given the estimated very low numbers of fruit bats currently on Guam that are found only within AAFB and the NAVMAG (16 miles [26 km] to the south), it is unlikely that fruit bats would occur within the Route 15 LFTRC action area. However, fruit bat recovery habitat is found within proposed project impacted areas on Route 15 lands (see Figure 3.8.3-1). Fruit bat recovery habitat was described by the USFWS in the BO for the Guam and CNMI Military Relocation (USFWS 2010a) and includes the following vegetation communities (based on vegetation mapping by the USFS [2006]) for foraging, roosting, and breeding: primary and secondary limestone forest, coconut plantation, ravine forest, and groves of ironwood.

**MARIANA SWIFTLET.** A nest/roost cave previously used by Mariana swiftlets is known from the Janum Springs area to the northeast of the proposed range area, but this cave was abandoned by the late 1970s (USFWS 1991). The last known occurrence of swiftlets within the Route 15 LFTRC action area was in 1998 when three individuals were observed along the coastal cliffline (GDAWR 1998). Surveys conducted in 2008 and 2009 for forest birds in support of the 2010 Final EIS did not record any incidental observations of Mariana swiftlets, although biologists did make concerted efforts to conduct early morning observations south of the abandoned nest/roost cave at Janum Springs (NAVFAC 2010). The only known occupied nest/roost caves on Guam are located on NAVMAG more than 16 miles (26 km) south of the Route 15 LFTRC action area. As swiftlets forage within 0.6-1.2 miles (1-2 km) of their nest/roost caves (Jenkins 1983), it unlikely that individuals from the only known population on Guam over 16 miles (26 km) away would occur within the Route 15 LFTRC action area. Therefore, as the Mariana swiftlet is not found within the impacted areas of Alternative 1, this species is not addressed further.

**MARIANA CROW.** The Mariana crow was last observed within the Route 15 lands in the 1970s (USFWS 2005). Since 2009, the population on Guam consisted only of two males on AAFB, occurring primarily within the MSA (USFWS 2009c). However, as of 2012, the Mariana crow is considered extirpated in the wild on Guam (Personal communication via letter from USFWS, Pacific Islands Fish and Wildlife Office, Honolulu, HI regarding the DON NOI for Proposed Placement of LFTRC on Guam NWR; December 7, 2012). The closest population of crows is on the island of Rota, approximately 56 miles (90 km) north of Guam. Crows in northern Guam used primary limestone forest for nesting, with nests exclusively in native trees. They have been observed foraging in both primary and secondary limestone forests and tangantangan (USFWS 2005). Crow recovery habitat is found within proposed project impacted areas on Route 15 lands (see Figure 3.8.3-1).

**GUAM RAIL.** The Guam rail has been extirpated in the wild on Guam since 1985 and exists primarily in captivity on Guam and in mainland zoos. Experimental populations of Guam rails were introduced onto Rota, CNMI in 1989 and onto Cocos Island, off the southern coast of Guam, in 2011 (USFWS 2009b; BirdLife International 2013). The Guam rail prefers edge habitats, especially grassy or secondary vegetation areas that provide good cover; mature forest is deemed only marginal for the Guam rail.
Guam rail recovery habitat is found within proposed project impacted areas on Andersen South and Route 15 lands (see Figure 3.8.3-2).

**GUAM MICRONESIAN KINGFISHER.** The Guam Micronesian kingfisher was extirpated in the wild by 1988 and is now found only in captivity on Guam and at mainland zoos (USFWS 2008b). Kingfishers utilized a wide variety of habitats including primary and secondary limestone forest, strand forest, coconut forest, edge habitats, and forest openings, but mature forests with tree cavities suitable for nesting may be an important requirement for kingfisher reproduction (USFWS 2008b). Kingfisher recovery habitat is found within proposed project impacted areas on Route 15 lands (see Figure 3.8.3-1).

**Slevin’s Skink.** Originally found on Guam, Cocos Island, Rota, Tinian, Guguan, Alamagan, Asuncion, and Maug, it is now limited to Cocos Island, Sarigan, Guguan, Alamagan, Pagan, and Asuncion. Slevin’s skink has not been recorded on Guam since 1945 and is believed to be extirpated from Guam; it is now known to occur only on Cocos Island (an atoll south of Guam) (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 1. Therefore, as Slevin’s skink is not found within the impacted areas of Alternative 1, this species is not addressed further.

**Mariana Eight-Spot Butterfly.** Two populations of the Mariana eight-spot butterfly have been reported in the Pågat area of the Route 15 lands. This butterfly is host-specific to the herbaceous plants *Procris pedunculata* and *Elatostema calcareum* (USFWS 2012a). During field surveys conducted for the 2010 Final EIS, several adult eight-spot butterflies and numerous host plant locations were observed within the Route 15 action area (Campora and Lee 2009) (see Figure 5.1.8-2). In July 2011, one adult male, one adult female, and nine eggs were located on the host plant *Procris pedunculata* near Guam International Raceway (Rubinoff and Kawahara 2011 as cited in USFWS 2012a). In 2013, surveys in the Route 15 project area observed eight-spot butterfly eggs, numerous chrysalis, and adults, and numerous clusters of host plants (UoG 2014).

**Mariana Wandering Butterfly.** The Mariana wandering butterfly has not been seen on Guam since 1979 and is considered extirpated; a single remaining population occurs on Rota, CNMI (USFWS 2013). The only species known to be a Mariana wandering butterfly host plant (*Maytenus thompsonii*) is a common shrub of limestone forests on Guam and has been observed within the impacted areas on Route 15 lands (see Figure 5.1.8-2) (Moore and McMakin 2001; UoG 2014).

**Tree Snails.** The three proposed endangered tree snail species have not been reported within the Route 15 LFTRC action area (NAVFAC 2010; USFWS 2014b). Surveys conducted in 2008, 2009, and 2013 for the 2010 Final EIS and this SEIS did not observe the species within the Route 15 LFTRC action area. Therefore, as tree snails are not found within the impacted areas of the Route 15 LFTRC Alternative, these species are not addressed further.

**Serianthes Tree.** There are no records of the species within the impacted areas associated with Alternative 1. However, *Serianthes* recovery habitat is found within proposed project impacted areas on the Route 15 lands (see Figure 3.8.3-2).

**Heritierea Longipetiolata.** This endemic tree is found on AAFB in crevices of rough limestone in primary limestone forest. A cluster of 22 mature trees and 184 seedlings of the *H. longipetiolata* tree were documented within the Route 15 lands near Guam International Raceway (Duenas & Associates 2000) (see Figure 5.1.8-2). In addition, one individual was observed along a survey transect southwest of this cluster (NAVFAC Pacific 2010).

**Tabernaemontana Rotensis.** Surveys conducted in 2008 and 2009 for the 2010 Final EIS did not observe the species within the Route 15 LFTRC lands and there are no records of the species within the
impacted areas (NAVFAC Pacific 2010; USFWS 2014b). Therefore, as *T. rotensis* is not found within the impacted areas of Alternative 1, this species is not addressed further.

**CYCAS MICRONESICA.** The cycad is found in limestone forests throughout Guam, including AAFB, and is proposed as an endangered species under the ESA because of the Asian cycad scale insect that is devastating the species. Surveys conducted in 2008 and 2009 for the 2010 Final EIS did not observe the species within the Route 15 LFTRC lands and there are no records of the species within the impacted areas (NAVFAC Pacific 2010; USFWS 2014b). Therefore, as *C. micronesica* is not found within the impacted areas of Alternative 1, this species is not addressed further.

**BULBOPHYLLUM GUAMENSE.** An epiphyte in the orchid family, this species occurs in mat-like formations on tree branches of coastal lowland/limestone forests. Currently, there are 8 known occurrences on Guam totaling fewer than 250 individuals (USFWS 2014a, 2014b). There are no records of the species within the impacted areas of the Route 15 LFTRC alternative (USFWS 2014b). Therefore, as *B. guamense* is not found within the impacted areas of Alternative 1, this species is not addressed further.

**DENDROBIUM GUAMENSE.** An epiphyte in the orchid family, this species occurs on tree branches of coastal lowland/limestone forests. Currently, there are 4 known occurrences on Guam with fewer than 250 individuals (USFWS 2014a, 2014b). Surveys conducted in 2008 and 2009 for the 2010 Final EIS did not observe the species within the Route 15 LFTRC lands and there are no records of the species within the impacted areas (NAVFAC Pacific 2010; USFWS 2014b). Therefore, as *D. guamense* is not found within the impacted areas of Alternative 1, this species is not addressed further.

**EUGENIA BRYANII.** A perennial shrub in the myrtle family, the species is known only from the island of Guam. Historically, *E. bryanii* is known from windy exposed coastal cliff lines and along the Pigua River, in lowland/limestone forests. Currently, *E. bryanii* is known from 6 occurrences totaling fewer than 420 individuals (USFWS 2014a, 2014b). There are no records of the species within the impacted areas of the Route 15 LFTRC alternative (USFWS 2014b). Therefore, as *E. bryanii* is not found within the impacted areas of Alternative 1, this species is not addressed further.

**MAESA WALKERI.** A shrub or small tree in the primrose family typically found in limestone forests, this species is known from only two individuals on Guam – one individual on Mt. Lamlam and one individual on Mt. Almagosa (USFWS 2014a). There are no records of the species within the impacted areas of the Route 15 LFTRC alternative (USFWS 2014b). Therefore, as *M. walkeri* is not found within the impacted areas of Alternative 1, this species is not addressed further.

**NERVILLA JACKSONIAE.** A small herb in the orchid family, this species is found in lowland/limestone forests. On Guam, *N. jacksoniae* is known from 2 occurrences totaling fewer than 200 individuals: 1 occurrence near the UoG campus and 1 occurrence to the northwest of Tarague Beach (USFWS 2014a, 2014b). There are no records of the species within the impacted areas of the Route 15 LFTRC alternative (USFWS 2014b). Therefore, as *N. jacksoniae* is not found within the impacted areas of Alternative 1, this species is not addressed further.

**PSYCHOTRIA MALASPINAE.** A shrub or small tree in the coffee family, this species is found in lowland/limestone forests. Currently, *P. malaspinae* is known from five occurrences: one individual at Ritidian Point within the Guam NWR, one individual at Pāgat Point, one individual at the base of Mt. Almagosa, and two individuals at NWF (USFWS 2014a, 2014b). None of these individuals have been observed within the last 5 years. A specimen collected from the Ritidian NWR in August 2013 is currently pending identification (USFWS 2014a). There are no records of the species within the impacted areas of the Route 15 LFTRC alternative (USFWS 2014b). Therefore, as *P. malaspinae* is not found within the impacted areas of Alternative 1, this species is not addressed further.

**SYCHOTRIA MALASPINAE**
areas of the Route 15 LFTRC alternative (USFWS 2014b). Therefore, as *P. malaspinæ* is not found within the impacted areas of Alternative 1, this species is not addressed further.

**Solanum guamense.** A small shrub in the nightshade family that occurs within limestone forests. Currently, *S. guamense* is known from a single occurrence of one individual on Guam (USFWS 2014a). There are no records of the species within the impacted areas of the Route 15 LFTRC alternative (USFWS 2014b). Therefore, as *S. guamense* is not found within the impacted areas of Alternative 1, this species is not addressed further.

**Tinospora homosepala.** A vine in the moonseed family found in limestone forests. Currently, *T. homosepala* is known from 3 occurrences totaling approximately 300 individuals: 1 occurrence on the western side of Asan Ridge; 1 occurrence near the War in the Pacific Historical Park; and 1 occurrence on the cliff face at Hagåtña (USFWS 2014a). There are no records of the species within the impacted areas of the Route 15 LFTRC alternative (USFWS 2014b). Therefore, as *T. homosepala* is not found within the impacted areas of Alternative 1, this species is not addressed further.

**Tuberolabium guamense.** An epiphyte in the orchid family found in limestone forests. Currently, *T. guamense* is known from three occurrences on Guam: two occurrences within the NAVMAG and one in the northeastern area of Finegayan (NAVFAC Pacific 2010; USFWS 2014a, 2014b). There are no records of the species within the impacted areas of the Route 15 LFTRC alternative (USFWS 2014b). Therefore, as *T. guamense* is not found within the impacted areas of Alternative 1, this species is not addressed further.

**Special-Status Species: Guam-Listed Species and Species of Greatest Conservation Need (SOGCN)**

**Moth Skink and Pacific Slender-Toed Gecko.** The moth skink and Pacific slender-toed gecko have not been reported from the Andersen South or Route 15 lands based on surveys conducted in support of the 2010 Final EIS (NAVFAC Pacific 2010). The closest known occurrence of both species is within central and western AAFB, more than 6 miles (9.7 km) to the north of the Alternative 1 action area. The lack of a continuous corridor of suitable habitat linking the Route 15 LFTRC action area and the known occurrences on AAFB, allowing for these species to move between areas, makes it unlikely that the species would occur within the Route 15 LFTRC action area. Therefore, as the moth skink and Pacific slender-toed gecko are not found within the impacted areas of the Route 15 LFTRC Alternative, these species are not addressed further.

5.1.8.2 Environmental Consequences

**Construction**

**Vegetation.** Under Alternative 1, 65 acres (26 ha) of primary limestone forest and 190 acres (77 ha) of secondary limestone forest would be removed during proposed construction activities of the LFTRC under Alternative 1 (Table 5.1.8-2; see Figure 5.1.8-1). In addition, 104 acres (42 ha) of currently developed areas and 47 acres (19 ha) of herbaceous scrub/grassland and tangantangan would be impacted (Table 5.1.8-2).
Table 5.1.8-2. Direct Impacts to Vegetation Communities with Implementation of LFTRC Alternative 1

Legend: PLF = primary limestone forest; SLF = secondary limestone forest; HS = herbaceous scrub; TT = tangantangan; Dev = developed.

Native limestone forest, both primary and secondary, has been significantly reduced on Guam due to past and ongoing actions including extensive disturbance during and after WWII, widespread planting of non-native species; and impacts from non-native ungulates; development; fire; and deforestation. As stated in Section 3.8.1.1, limestone forests on Guam are important since they retain the functional ecological components of native forest that provide habitat for the majority of Guam’s native species, including ESA-listed, ESA-proposed, and Guam-listed species and Guam SOGCN, as well as maintaining water quality and reducing fire risk. Non-native forest communities (e.g., tangantangan, Vitex) significantly alter the forest structure, composition, and resilience to other disturbance processes and do not provide the conditions suitable for native flora and fauna species to persist (Morton et al. 2000; GDAWR 2006; Guam Department of Agriculture 2010; JRM 2013).

Of the 18,538 acres (7,502 ha) of primary and secondary limestone forest found on Guam, approximately 13,110 acres (5,305 ha) (or 71%) are found primarily within AAFB, Finegayan, and NAVMAG (USFS 2006). Under Alternative 1, approximately 255 acres (103 ha) of limestone forest would be removed, primarily within the Route 15 lands (see Table 5.1.8-2). Therefore, given the importance of primary and secondary limestone forest habitat for native species and the continuing loss of native limestone forest across Guam, the conversion of 255 acres (103 ha) of limestone forest on Andersen South and the Route 15 lands to developed area would be a significant but mitigable impact to the regional vegetation community and its function.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct, long-term impacts of proposed construction activities on vegetation communities with implementation of LFTRC Alternative 1. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the contractor education program.
- **Onsite Vegetation Waste Management Procedures.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the vegetation waste management procedures.
- **DON Guam Landscaping Guidelines.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of landscaping guidelines.
• **LFTRC Range Berm Controls.** To manage stormwater runoff and control erosion, LFTRC range berms would contain native or non-invasive herbaceous vegetation and other engineering controls.

• **Contractor Plans and Specifications.** All construction would occur within the limits of construction shown in the project figures.

### Potential Mitigation Measures

To mitigate for significant impacts to limestone forest, the DON proposes to implement forest enhancement on a minimum of 255 acres (103 ha) of limestone forest. Forest enhancement would include but is not limited to the following actions:

- Ungulate management consisting of exclusion fencing and active control (i.e. trapping, snaring, shooting) with the goal of eradication within the fenced areas.
- Non-native, invasive vegetation removal.
- Propagation, planting, and establishment of native species that are characteristic of native limestone forest habitats (e.g., *A. mariannensis*, *G. mariannae*, *F. prolixa*, *M. citrifolia*, *W. elliptica*).

The degradation and loss of primary limestone and other forest habitats resulting from ungulate damage and invasion by alien plant species has substantially diminished the extent of habitat for native species in the Mariana archipelago. The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including special-status species. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

### Terrestrial Conservation Areas

As there are no terrestrial conservation lands designated within the Route 15 lands or Andersen South, there would be no impacts to terrestrial conservation lands with implementation of construction activities associated with LFTRC Alternative 1.

**Wildlife - Native Species.** There is no new information for wildlife in the Alternative 1 action area, and the impact assessment would be the same as that described in the 2010 Final EIS for a similar LFTRC alternative at Route 15 (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.4.2: Non-DoD Land, pages 10-54 to 10-59). Therefore, there would be less than significant impacts to wildlife species with implementation of Alternative 1.

The following BMPs would be implemented to avoid and minimize potential direct, long-term impacts of proposed construction activities on native wildlife with implementation of Alternative A.

#### Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the contractor education program.
- **Brown Treessnake Interdiction.** The DoD has a long history of success in preventing the dispersal of the brown treesnake from Guam in its transport of personnel and cargo (USFWS 2010a). After the publication of the 2009 Guam and CNMI Military Relocation Draft EIS, various agencies within the U.S. Department of Interior expressed concern regarding the
adequacy of brown treesnake interdiction efforts in response to the relocation of Marine Corps forces to Guam. For the purposes of the 2010 Final EIS and this SEIS, interdiction is defined as: “to hinder, prohibit, or prevent the brown treesnake from becoming established in new locations by conducting inspection and suppression processes.” The DON agrees that it will fund the increase of current federally funded brown treesnake interdiction measures (in Guam, CNMI, and Hawaii) where the increase is related to direct, indirect and induced growth caused by the Marine Corps relocation to Guam. That funding will continue and become part of the DON’s current brown treesnake interdiction funding under authority of the Brown Tree Snake Control and Eradication Act (USFWS 2010a).

JRM has established a comprehensive brown treesnake interdiction program to ensure that military activities, including the transport of civilian and military personnel and equipment to and from Guam, do not contribute to the spread of brown treesnakes to other islands or regions. Brown treesnake interdiction requirements (e.g., trapping and inspections at ports and cargo facilities, aircraft, inspections of household good movements, biosecurity plans for training events) are specified in the DoD instructions (i.e., 36 Wing Instruction 32-7004, Brown Tree Snake Control Plan and COMNAVMAR Instruction 5090.10A, Brown Tree Snake Control and Interdiction Plan) as well as the annual Work Financial Plan that is developed in cooperation with USDA Wildlife Services. The proposed action would continue to comply with these established procedures.

With implementation of these BMPs, including development of HACCP plans and ongoing implementation of standard DON biosecurity protocols regarding detection and management of non-native species, the risk of the introduction and establishment of new or spread of existing non-native species on Guam is substantially reduced. Therefore, there would be less than significant impacts to native wildlife species related to the potential introduction and establishment of non-native species with implementation of proposed construction activities associated with Alternative 1.

Damage of forested areas, particularly primary and secondary limestone forests, by non-native ungulates (i.e., deer and pigs) is a serious concern on Guam. Under Alternative 1, removal of large amounts of secondary limestone forest currently used by ungulates would displace and concentrate ungulates into adjacent areas, resulting in even higher densities and potentially greater habitat damage. Potential impacts from changes in ungulate densities from construction projects within the same or similar habitat areas as proposed in this SEIS were addressed in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.2.1: North, page 10-115).

**Special-Status Species: Federal ESA-Listed and Proposed Species**

**MARIANA FRUIT BAT.** There are no historical fruit bat roost sites at Andersen South or the Route 15 lands and the last observation of a fruit bat within the Alternative 1 project areas was in 1999. However, there is fruit bat recovery habitat within the impacted areas of the Route 15 lands. Approximately 81 acres (33 ha) of Mariana fruit bat recovery habitat would be removed due to proposed construction activities at Andersen South and the Route 15 lands under Alternative 1 (Table 5.1.8-3). This area is included in the impacts to vegetation discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.
Additional potential direct temporary impacts to the Mariana fruit bat from construction activities are based on the distances from those activities that are likely to cause disturbance to this species (e.g., noise, human activity, lighting). The evaluation of fruit bat disturbance is based on the approach used by USFWS in previous ESA section 7 formal consultations and associated BOs (e.g., USFWS 2006b, 2010). These distances are: roosting habitat within 492 feet (150 m) and foraging habitat within 328 feet (100 m) from the activity (Wiles, personal communication 2006] and Janeke, personal communication 2006, respectively, as cited in USFWS 2006b).

The species is currently limited to the few areas on Guam away from human activities and with suitable habitat, primarily on the NAVMAG and AAFB (JRM et al. 2012a, 2012b; JRM 2013; A. Brooke, NAVFAC Marianas, personal communication). However, illegal hunting, loss and degradation of native forest, predation by the brown treesnake, and the increased extirpation risk owing to the high vulnerability of very small populations continue to limit the potential recovery of the species on Guam (USFWS 2010a; JRM 2013). Based on the equilibrium/carrying capacity of snakes on Guam (Rodda and Savidge 2007), implementation of the proposed action is not expected to increase the likelihood of predation by the brown treesnake on Mariana fruit bats.

The loss of 81 acres (33 ha) of fruit bat recovery habitat on Guam would not preclude the recovery or survival of the fruit bat, and it would not substantially reduce the total number of bats that the island can support. Given this small loss of recovery habitat, there would be less than significant impacts to the Mariana fruit bat with implementation of proposed construction activities associated with Alternative 1.

The following BMPs may be implemented to avoid and reduce potential direct long-term impacts of proposed construction activities on Mariana fruit bats and recovery habitat with implementation of Alternative 1.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the contractor education program.
- **Pre-Construction Surveys.** Surveys would be completed within suitable fruit bat habitat 1 week prior to onset of construction activities following the USFWS-approved JRM protocol. If a fruit bat is present within 492 feet (150 m) of the project site, the work must be postponed until the bat has left the area.
- **Lighting Installation.** Lighting would be designed to meet minimum safety and AT/FP requirements. Hooded lights would be used to the maximum extent practicable at all new roads and facilities adjacent to fruit bat habitat. Illumination of forest would be kept to an absolute minimum.
In addition, the potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 255 acres [103 ha] of limestone forest) would provide additional benefit to bat recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

MARIANA CROW. The Mariana crow is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the crow is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the crow, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the crow is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative 1, impacts to the crow would be limited to recovery prospects. If the crow is reintroduced and exposed to construction activities under Alternative 1, they may be disturbed (DON 2014).

Although the crow no longer occurs on Guam, approximately 81 acres (33 ha) of crow recovery habitat would be removed due to proposed construction activities at Andersen South and the Route 15 lands under Alternative 1 (Table 5.1.8-4). This area is included in the impacts to vegetation discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

</tbody>
</table>

The loss of 81 acres (33 ha) of crow recovery habitat on Guam would not preclude the recovery or survival of the crow, and it would not substantially reduce the total number of crows that the island can support should it be reintroduced to Guam in the future. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to the Mariana crow with implementation of proposed construction activities associated with Alternative 1. If and when the crow is reintroduced to Guam, the best available information indicates project-related noise would not further reduce the amount of recovery habitat suitable for this species’ breeding, feeding and sheltering (USFWS 2010a).

The following BMPs may be implemented to avoid and reduce potential direct long-term impacts of proposed construction activities on Mariana crow recovery habitat with implementation of Alternative 1.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Brown Treesnake Interdiction.** See the above discussion of BMPs under Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

In addition, the potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 255 acres [103 ha] of limestone forest) and Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW (i.e., brown treesnake research and suppression program) would provide additional benefit to crow recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Mariana crow.

GUAM RAIL. The Guam rail is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the rail is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the rail, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the rail is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative 1, impacts to the rail would be limited to recovery prospects. If the rail is reintroduced and exposed to construction activities under Alternative 1, they may be disturbed (DON 2014).

Although the rail no longer occurs on Guam, approximately 283 acres (115 ha) of rail recovery habitat would be removed due to proposed construction activities at Andersen South and the Route 15 lands under Alternative 1 (Table 5.1.8-5). This area is included in the impacts to vegetation discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

</tbody>
</table>

Although the loss of 283 acres (115 ha) of rail recovery habitat on Guam would not preclude the recovery of the rail should it be reintroduced to Guam in the future, it would reduce the total number of rails that the island can support. Given this loss of recovery habitat, there would be significant but mitigable impacts to the recovery of the Guam rail.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct and indirect long-term impacts of proposed construction activities on the recovery of the Guam rail with implementation of Alternative 1. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.
Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

Potential Mitigation Measures

- **Brown Treesnake Suppression or Eradication.** See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW for a detailed description of the brown treesnake suppression or eradication program.
- The same potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 255 acres [103 ha] of limestone forest) would benefit Guam rail recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Guam rail, should it be reintroduced to Guam in the future.

**Guam Micronesian Kingfisher.** The kingfisher is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the kingfisher is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the kingfisher, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the kingfisher is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative A, impacts to the kingfisher would be limited to recovery prospects. If kingfishers are reintroduced and exposed to construction activities under Alternative 1, they may be disturbed (DON 2014).

Although the kingfisher no longer occurs on Guam, approximately 81 acres (33 ha) of kingfisher recovery habitat would be removed due to proposed construction activities at Andersen South and the Route 15 lands under Alternative 1 (Table 5.1.8-6). This area is included in the impacts to vegetation discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

The loss of 81 acres (33 ha) of kingfisher recovery habitat on Guam would not preclude the recovery or survival of the kingfisher, and it would not substantially reduce the total number of kingfishers that the island can support should it be reintroduced to Guam in the future. Given this small loss of recovery habitat, there would be less than significant impacts to the kingfisher with implementation of proposed construction activities associated with Alternative 1.

The following BMPs may be implemented to avoid and reduce potential direct long-term impacts of proposed construction activities on kingfisher recovery habitat with implementation of Alternative 1.

Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

In addition, the potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 255 acres [103 ha] of limestone forest) and Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW (i.e., brown treesnake research and suppression program) would provide additional benefit to kingfisher recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

**MARIANA EIGHT-SPOT BUTTERFLY.** Host plants and adult, immature, and egg stages of the eight-spot butterfly have been observed within the Route 15 lands during surveys in support of the 2010 Final EIS and this SEIS (Campora and Lee 2009; NAVFAC Pacific 2010; UoG 2014).

Some species of tropical butterflies have well-developed ears on their wings and can detect sounds at the same frequencies that humans can hear. It is hypothesized that the butterflies are listening to the flight sounds or foraging calls of predatory birds (Lane et al. 2008; Yack 2012). Given the low numbers of forest birds currently on Guam due to the brown treesnake, masking of the flight sounds or foraging calls of predatory birds due to noise from proposed construction activities would not make eight-spot butterflies more susceptible to predation.

With implementation of appropriate BMPs to avoid and minimize potential impacts to eight-spot butterflies (e.g., pre-construction butterfly and host plant surveys within the proposed range areas and salvage/relocation of host plants, larvae or eggs; see Table 2.8-1), there would be less than significant impacts to the Mariana eight-spot butterfly with implementation of proposed construction activities under Alternative 1. In addition, implementation of the potential mitigation measures described above under Vegetation (i.e., forest enhancement of 255 acres [103 ha] of limestone forest) would also benefit the survival the eight-spot butterfly. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species, including eight-spot butterfly host plants.

**SERIANTHES TREE.** Although individual Serianthes trees do not occur within the impacted areas of Alternative 1, approximately 67 acres (27 ha) of Serianthes recovery habitat would be removed due to proposed construction activities at Andersen South and the Route 15 lands under Alternative 1 (Table 5.1.8-7). This area is included in the impacts to vegetation discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.
Table 5.1.8-7. Summary of Direct Construction-Related Impacts to *Serianthes* Recovery Habitat with Implementation of Cantonment/Family Housing Alternative 1

<table>

<tr>
<td><strong>Total Recovery Habitat Impacted</strong></td>
<td><strong>67.0 (27.1)</strong></td>
</tr>
</tbody>
</table>

The loss of 67 acres (27 ha) *Serianthes* recovery habitat on Guam would not preclude the recovery of *Serianthes*, and it would not substantially reduce the total number of *Serianthes* that the island can support. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to *Serianthes* with implementation of proposed construction activities associated with Alternative 1.

The following BMPs may be implemented to avoid and minimize, potential direct long-term impacts of proposed construction activities on the recovery of *Serianthes* with implementation of Alternative 1.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2, *Construction, Vegetation* for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, *Construction, Vegetation* for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, *Construction, Vegetation* for a detailed description of the contractor education program.

The implementation of the potential mitigation measures discussed above under *Vegetation* (i.e., forest enhancement of 255 acres [103 ha] of limestone forest) would benefit *Serianthes* habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

*Heritiera longipetiolata*. An individual tree and a cluster of 22 mature trees and 184 seedlings of *H. longipetiolata* were observed within the proposed MPMG Range footprint during previous surveys of the area (Duenas & Associates 2000) and during surveys for the 2010 Final EIS (NAVFAC Pacific 2010) (see Figure 5.1.8-2). Under Alternative 1, all *H. longipetiolata* would be avoided to the maximum extent practicable during proposed construction activities. With implementation of BMPs, such as salvaging high-value (both biologically and culturally) plant species during construction activities and potential translocation of *Heritiera* trees, particularly seedlings (see Section 2.8), there would be less than significant impacts to *H. longipetiolata* resulting from proposed construction activities under Alternative 1.

**Special-Status Species: Guam-Listed and SOGCN**

Guam-listed species and SOGCN are also ESA-listed species and are discussed above.

**Operation**

*Vegetation*. With implementation of BMPs (see previous discussion of construction impacts under *Vegetation*), including ongoing implementation of standard DON and commercial biosecurity protocols (e.g., Port of Guam, A.B. Won Pat International Airport) regarding detection and management of non-native species, invasive species outreach and education, 1-year post-construction monitoring to evaluate effectiveness of HACCP, and applicable elements of the SIP, the potential for the introduction of new or
spread of existing non-native species on Guam during the operation of Alternative 1 is considered unlikely. Therefore, there would be less than significant impacts to vegetation with operation of the proposed LFTRC under Alternative 1.

Fire potential would increase due to proposed live-fire range operations. Fire can result in direct effects to vegetation by increasing erosion, allowing for the establishment of non-native species, and altering wildlife habitat by reducing food resources, breeding habitat, and shelter. Native plants and their habitats on Guam are adapted to a humid, tropical climate and are not adapted to a fire driven ecosystem (USFWS 2008a). Fire is a serious problem on Guam. Fire history records available from 1979 - 2002 indicate that over this 23-year period more than 16,000 fires have occurred in Guam (averaging more than 700 per year) that have burned in excess of 100,000 acres (40,469 ha), primarily in southern Guam. Of these 16,000 fires, 477 of them occurred on Naval Base Guam, primarily at Apra Harbor and NAVMAG, burning more than 9,800 acres (3,966 ha) (Nelson 2008).

As a BMP and in accordance with range safety protocols, a Range Fire Management Plan would be prepared, based on the DON’s Wildland Fire Management Plan (Nelson 2008) (see Section 2.8). It would include protocols for monitoring fire conditions and adjusting training as needed (e.g., certain types of training may be disallowed under certain fire conditions), and location and management of firebreaks, fire-fighting roads, and a fire fighting water system. Units undergoing training would be briefed on requirements suitable to the conditions of the day and protocols should a fire occur (e.g., specifying how the range would shut down and how fire suppression action would be taken). With implementation of the Range Fire Management Plan, which establishes management and fire suppression and emergency response procedures, potential impacts from range-related wildfires would be less than significant. The USFWS concluded in their BO for the 2010 Final EIS that they anticipated that no additional vegetation would be lost due to wildfires igniting as a result of proposed live-fire training operations (USFWS 2010a). Therefore, there would be less than significant impacts to vegetation from operation of LFTRC Alternative 1.

Terrestrial Conservation Areas. As there are no terrestrial conservation lands designated within the Route 15 lands or Andersen South, there would be no impacts to terrestrial conservation lands with implementation of operational activities associated with LFTRC Alternative 1.

Wildlife - Native Species. Operational impacts to native wildlife would include an increase in noise and lighting. These potential impacts were evaluated in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.2.2: Central, page 10-129) for a similar proposed action, and were found to be not significant.

With implementation of BMPs (see previous discussion of construction impacts under Vegetation), including ongoing implementation of standard DON and commercial biosecurity protocols (e.g., Port of Guam, A.B. Won Pat International Airport) regarding detection and management of non-native species, invasive species outreach and education, 1-year post-construction monitoring to evaluate effectiveness of HACCP, and applicable elements of the SIP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of the proposed LFTRC under Alternative 1 is considered unlikely. The DON recognizes the USFWS’ ongoing concern regarding potential spread of the brown treesnake. The DON will consult with USFWS under ESA section 7 to determine if additional brown treesnake interdiction measures are warranted and applicable. In addition, lighting associated with the range and support areas would be hooded or shielded to the maximum extent practicable to prevent unnecessary light beyond operational areas. Therefore, there would be less than significant impacts to native wildlife with operation of the proposed LFTRC under Alternative 1.
Special Status Species: Federal ESA-Listed and Proposed Species

MARIANA FRUIT BAT. As the Mariana fruit bat does not occur at the proposed HG Range at Andersen South, there would be no impacts to Mariana fruit bats from noise associated with operation of the HG Range.

For those species of fruit bats that have been tested for hearing sensitivity, their audiograms are very similar to those of humans, with similar upper and lower frequency limits and hearing threshold levels (Calford et al. 1995; Koay et al. 1998; Heffner et al. 2006). Therefore, it is likely that noise from live-fire operations at the proposed ranges would be heard by fruit bats as it would be heard by humans.

The USFWS established 60 dB and 93 dB as two thresholds of biological significance based on their review of impacts of noise to wildlife. Noise levels above 60 dB have been found to affect acoustic communication, breeding biology, survival of young, and non-auditory bird and mammal physiology. Noise levels above 93 dB may temporarily or permanently affect hearing (USFWS 2010a). No species would be exposed to noise levels of 93 dB or greater under the proposed action. While noise levels may approach 93 dB in the immediate vicinity of the firing of an individual weapon, fruit bats or other wildlife species would not be in proximity to the live-fire event given the location and nature of weapons firing within a developed range area.

Responses to noise can vary among individuals as a result of habituation where after a period of exposure to a stimulus, an animal stops responding to the stimulus. In general, a species can often habituate to human-generated noise when the noise is not followed by an adverse impact. Even when a species appears to be habituated to a noise, the noise may produce a metabolic or stress response (increased heart rate results in increased energy expenditure) though the response may or may not lead to changes in overall energy balance. Anthropogenic noise disturbance is known to alter animal behavioral patterns and lead to population declines (Barber et al. 2011; Francis and Barber 2013; McGregor et al. 2013).

In addition to noise level, the frequency and regularity of the noise also affect species sensitivity. That is, different types of noise sources will produce different effects on different species. Noise from aircraft overflights may not produce the same response from a wildlife species as noise from a land-based noise source such as a vehicle, chainsaw, or gun shot. Wildlife species often do not react only to a noise source but more importantly to the visual component associated with that noise source. Nesting birds will react to a noise source by tilting their head, becoming alert, etc. but often do not leave the nest or perch until there is a visual connection with the noise source. For example, birds may not react to just the sound of a chainsaw, but when that sound is coupled with a human walking near the bird, the bird will flush. This is also shown in reactions by various species to aircraft overflights (airplanes and helicopters). An overflight with just a sound component does not elicit a strong response, but if an animal hears and then sees the aircraft, the bird will more likely flush and move away (Bowles 1995; Krausman et al. 1993; Manci et al. 1988; USFS 1992). In other words, human intrusions near roost sites, nests, foraging areas, etc. (e.g., timber harvesting, hiking, hunting) are readily detectable and substantial (USFS 1992).

Species that are commonly hunted often demonstrate behavioral (e.g., flushing, startle response) or physiological responses (e.g., increased heart rates, increased respiration rates) to gunshot sounds (Larkin et al. 1996). Knight et al. (1987) found that American crows nesting in urban areas were less wary of people than American crows nesting in rural habitat and attributed the difference to the hunting of rural crows. Barron et al. (2012) found that American crows avoided areas with live-fire exercises in a similar fashion and suggested that species hunted by humans will be more adversely affected by human activity, including military training (e.g., live-fire training) than species that are not hunted.
As stated by Morton and Wiles (2002), “Poaching is a particularly insidious activity because not only does it impact fruit bats through mortality, it reinforces behavioral avoidance of humans. Consequently, roosting or foraging fruit bats that might not otherwise be disturbed by some human activities … may become unduly sensitized to them because of illegal hunting.” Based on observations on Guam and Rota, fruit bats have abandoned areas where hunting has occurred and did not return even though no further hunting or gunshots occurred within the area for months after (Janeke 2006; AAFB 2008b; USFWS 2009a; Mildenstein and Mills 2013). In addition, anecdotal evidence from numerous individuals who have conducted fruit bat research on Guam and the CNMI for many years indicate that fruit bats do avoid areas that have been previously subjected to hunting and also areas that experience live-fire activities (G. Wiles, Washington Department of Fish and Wildlife, personal communication, 2014; T. Mildenstein, University of Montana, personal communication, 2014; D. Janeke, HDR, Inc., personal communication, 2014; N. Johnson, Marianas Conservation Unlimited, personal communication, 2014). For example, during fruit bat monitoring at AAFB near the CATM range as part of a larger study monitoring the effects of aircraft overflights on fruit bats and crows (JRM et al. 2012b), flying fruit bats were observed avoiding the CATM range by 300-400 m when live-fire operations were being conducted (N. Johnson, Marianas Conservation Unlimited, personal communication, 2014).

However, a species can also habituate to human-generated noise when the noise is not followed by an adverse impact. While fruit bats may avoid an area subjected to hunting and the associated gun shots, fruit bats, like most wildlife species, will also learn that if a disturbance or sound does not produce an adverse effect (e.g., mortality), then they can habituate to that disturbance or sound and will not show an adverse reaction (e.g., flying away, avoiding the area) (Boyle and Samson 1985; Francis and Barber 2013).

Most of the effects of noise are mild enough that they may never be detectable as variables of change in population size or population growth against the background of normal variation (Bowles 1995). Other environmental variables (e.g., predators, weather, changing prey base, ground-based disturbance) may influence reproductive success and confound the ability to identify the ultimate factor in limiting productivity of a certain species, area, or region (Smith et al. 1988).

Based on identified recovery habitat for the Mariana fruit bat (USFWS 2010b), noise levels of 60 dB ADNL and greater would overlie 669 acres (271 ha) of recovery habitat in the vicinity of Alternative 1 (Table 5.1.8-8 and Figure 5.1.8-3).

Given the ongoing poaching of fruit bats on Guam, it is likely that those fruit bats that currently occur on Guam will avoid areas of live-fire training as they may have experienced a poaching event. While there is the potential for eventual habituation by fruit bats to LFTRC live-fire activities, fruit bats are expected to initially avoid areas of live-fire training activities. Therefore, fruit bats may temporarily avoid approximately 669 acres (271 ha) of recovery habitat due to proposed live-fire range operations. However, proposed live-fire operations at the LFTRC are not continuous and would occur between 7:00 am and 7:00 pm for 39 weeks per year, and night operations (estimated to occur 2 nights per week over 39 weeks per year) would occur between 7:00 pm and 10:00 pm or 6:00 am and 7:00 am. In addition, live-fire operations would not physically impact recovery habitat. This temporary avoidance of recovery habitat on Guam would not preclude the recovery or survival of the fruit bat, and it would not substantially reduce the total number of fruit bats that the island can support. Therefore, there would be less than significant impacts to the Mariana fruit bat with implementation of proposed operational activities associated with Alternative 1.

MARIANA CROW, GUAM RAIL, AND GUAM MICRONESIAN KINGFISHER. These species are extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of these species is reasonably certain to occur and the species are likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of these species, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the crow, rail, and kingfisher are successfully re-introduced and then have the potential to be exposed to operational activities under Alternative 1, there would be no impact to these species. If the species are reintroduced and exposed to LFTRC operational activities under Alternative 1, they may be disturbed.

MARIANA EIGHT-SPOT BUTTERFLY. Some species of tropical butterflies have well-developed ears on their wings and can detect sounds at the same frequencies that humans can hear. It is hypothesized that the butterflies are listening to the flight sounds or foraging calls of predatory birds (Lane et al. 2008; Yack 2012). Given the low numbers of forest birds currently on Guam due to the brown treesnake, masking of the flight sounds or foraging calls of predatory birds due to noise from proposed construction activities would not make eight-spot butterflies more susceptible to predation.

Although fire potential could increase due to proposed live-fire range operations, with implementation of the proposed Range Fire Management Plan and procedures (see Vegetation above, and Section 2.8), potential impacts from range-related wildfires on Mariana eight-spot butterfly would be less than significant. Therefore, as operation of the range would not remove additional vegetation (e.g., host plants), there would be less than significant impacts to the Mariana eight-spot butterfly with implementation of proposed range operations under Alternative 1.

SERIANTHES TREE. Serianthes does not occur within the Alternative 1 action area. Although fire potential could increase due to proposed live-fire range operations, with implementation of the proposed Range Fire Management Plan and procedures (see Vegetation above, and Section 2.8), potential impacts from range-related wildfires on Serianthes would be less than significant. Therefore, there would be less than significant impacts to Serianthes or recovery habitat due to proposed range operations under Alternative 1.

HERITIERA LONGIPETIOLATA. Although fire potential could increase due to proposed live-fire range operations, with implementation of the proposed Range Fire Management Plan and procedures (see
Vegetation above, and Section 2.8), potential impacts from range-related wildfires on *H. longipetiolata* would be less than significant due to proposed range operations under Alternative 1.

**Special-Status Species: Guam-Listed and SOGCN**

Guam-listed species and SOGCN are also ESA-listed species and are discussed above.

### Marine Biological Resources

#### 5.1.9 Affected Environment

The description of the affected environment for marine biological resources associated with the proposed Route 15 LFTRC alternative is found in the 2010 Final EIS and is summarized below for reference (Volume 2, Chapter 11: Marine Biological Resources, Section 11.1.6.3: Non-DoD Land, pages 11-51 to 11-54).

**Marine Flora and Invertebrates**

Site-specific information is limited for this area (Pågat Point). However, marine flora and invertebrate information would be similar to that described for Guam generally in the 2010 Final EIS (Volume 2, Chapter 11: Marine Biological Resources, Section 11.1.4: Guam Regional Environment, pages 11-11 to 11-42).

The shoreline along the proposed Route 15 LFTRC consists of exposed rocky shores and an intertidal beach providing habitat for many intertidal invertebrate species, including octopi, sea cucumbers, swimming crabs, and slipper and spiny lobsters. The nearshore environment generally contains areas of 10-50% coral cover and unconsolidated sediment, with minimal coralline algae, macroalgae (including seagrass), and turf algae (Figure 5.1.9-1). Corals found above the 100-foot (30-m) isobath in this area typically include encrusting, massive, columnar, platy, and branching growth forms of corals conditioned by the dominant trade winds and strong wave action to withstand physically harsh conditions (Navy 2005 [as cited in 2010 Final EIS]).

**Fish**

The extent to which the coastal waters off Route 15 are used for commercial, recreational or subsistence fishing is not known. However, this area has a much lower overall fish biomass than Guam’s marine protected areas (Williams *et al.* 2012).

**Essential Fish Habitat**

Site-specific information is limited for this study area (Pågat Point). However, general EFH information would be similar to that described in the 2010 Final EIS (Volume 2, Chapter 11: Marine Biological Resources, Section 11.1.4.2: Essential Fish Habitat, pages 11-18 to 11-36), and includes a host of juvenile and adult fish and invertebrate MUS with year-round residence.

**Special-Status Species**

In the absence of specific habitat or distribution limitations, all four species of coral listed as threatened under the ESA are considered as possibly occurring in any of the alternative study areas for which marine biological resources are analyzed, in this case Route 15 (see Table 3.9.1-2).

Sources: NOAA 2005a, b; NAVFAC Pacific 2013
There are no reported sea turtle nesting beaches or foraging areas in this vicinity (NOAA 2005a [as cited in the 2010 Final EIS]). However, green sea turtles, and to a lesser degree, hawksbill turtles may be present in the coastal waters. The nearest reported nesting beach from Pågat Point is located south of Pago Bay, approximately 5 miles (8 km) south of the Route 15 lands. The nearest potential foraging area is at Taguan Point, approximately 2 miles (3 km) south of the Route 15 lands.

**Marine Conservation Areas**

There are no marine conservation areas at or adjacent to Alternative 1.

**5.1.9.2 Environmental Consequences**

**Construction**

*Marine Flora and Invertebrates*

There is no in-water construction work proposed for the construction of Alternative 1. Therefore, there are no anticipated direct impacts to marine resources. The measures used to minimize potential impacts from construction activities, including appropriate resource agency specific BMPs, construction and industrial permit BMPs, LID features in accordance with the DoD UFC LID (UFC 3-210-10) and Section 438 of the EISA, USACE permit conditions, and general marine resources protective measures, are described in the 2010 Final EIS (Volume 7 and Volume 2, Chapter 11: Marine Biological Resources, Section 11.2: Environmental Consequences, pages 11-70 to 11-71) and summarized in Chapter 2 of this SEIS. Specifically, the site-specific SWPPP within the Construction General Permit would identify appropriate BMPs for the site that would serve to contain runoff and sediment on-site by reducing the flow rate of runoff and thereby minimize suspension of sediment and promote infiltration of runoff.

Contract construction personnel would be issued base passes for official business only and these restrictions would be specified in construction contracts. Increased recreational use of the marine resources near Alternative 1 is therefore expected to be minimal.

The DON plans to educate construction workers via environmental awareness training on the importance of coastal ecosystems and the proper way to interact with those resources to avoid and minimize damage to reefs typically caused by anchors, reef-walkers, or scuba diving, snorkeling, and fishing activities around Guam. The above measures would reduce indirect short-term impacts by the construction workforce on marine flora and invertebrates to less than significant.

*Fish*

The construction of Alternative 1 would result in no direct impacts and less than significant indirect impacts to fish for reasons consistent with those given above for marine flora and invertebrates. There would be no impacts to fish from stormwater, sedimentation, or other non-point source pollution from construction projects due to compliance with the Construction General Permit and the implementation of appropriate construction BMPs.

*Essential Fish Habitat*

The construction of Alternative 1 would result in no direct impacts and less than significant indirect impacts to EFH for reasons consistent with those given above for marine flora and invertebrates. There would be no impacts to EFH from stormwater, sedimentation, or other non-point source pollution from construction projects due to compliance with the Construction General Permit and the implementation of appropriate construction BMPs.
Per the Magnuson-Stevens Fishery Conservation and Management Act, there would be no adverse effects on EFH because construction of the proposed action would not reduce the quality or quantity of EFH with implementation of access restrictions, environmental education and outreach for the construction workforce, and the Construction General Permit and appropriate construction BMPs.

**Special-Status Species**

There would be no direct or indirect impacts special-status species as a result of the proposed action with compliance with the Construction General Permit, implementation of appropriate construction BMPs, and access limitations for construction workers, as described for the resources above.

Increased dive boat operations have the potential for increased turtle harassment and strikes. However, because of the mobility of sea turtles combined with implementation of sea turtle specific BMPs, potential increased recreational activities would result in less than significant impacts to sea turtles. In addition, any such impacts to the sea turtle population would be reduced in intensity from the previously proposed action evaluated in the 2010 Final EIS and the proposed action assessed in this SEIS would continue to be in compliance with the 2010 NMFS BO.

**Marine Conservation Areas**

There are no marine conservation areas in the vicinity Alternative 1. Therefore, there would be no impacts to such areas.

**Operation**

Potential impacts to marine biological resources as a result of operation of the proposed live-fire training ranges and associated range operation and control facilities at Route 15 are assessed below, but are generally described in the 2010 Final EIS for the Route 15 alternatives (Volume 2, Chapter 11: Marine Biological Resources, Section 11.2.2.2: Central, pages 11-85 to 11-92).

For analytical purposes, a very small number of rounds fired at all proposed ranges would fall outside the range footprint, but within the SDZ. This is based on ricochets, not direct fire, meaning the speed of the bullet, and therefore the distance traveled, would be reduced after the bullet deflected off a surface. The 2010 Final EIS described an analysis conducted using a combination of Marine Corps and Army methodology to determine the probability of direct strikes to a marine mammal, which found a very low likelihood that a projectile would come in contact with a dolphin (0.08524 dolphins per year), with an even lower possibility of imparting significant injury to the animal. Should munitions land in the water, the rapid sinking rate of such munitions is expected to preclude ingestion by marine organisms.

Scoping comments for this SEIS noted concern regarding the possibility that contamination could migrate from the ranges through stormwater runoff. However, as discussed in Section 5.2.2, Water Resources, there would be no impacts to nearshore waters through implementation of surface water protection measures (i.e., compliance with Construction General Permit requirements and implementation of BMPs during construction and implementation of LID features in accordance with the DoD UFC LID (UFC 3-210-10) and Section 438 of the EISA, range maintenance BMPs, and pollution prevention plans during operations). Specifically, the site-specific SWPPP within the Construction General Permit would identify appropriate BMPs for the site that would serve to contain runoff and sediment on-site by reducing the flow rate of runoff and thereby minimize suspension of sediment and promote infiltration of runoff. In addition, LID measures would include vegetated swales for conveyance and detention/retention ponds capable of capturing, storing, and treating additional runoff from the 25-year design storm. For each basin, water quality treatment strategies were selected based on the effectiveness of BMPs to treat
identified pollutants of concern from proposed land uses within that basin. Implementation of LID would ensure that there would be no increase in off-site transport of excess stormwater runoff, sediment, or other pollutants for up to the 25-year design storm event.

In addition, erosion control, sediment runoff control, spent munitions containment strategies would be implemented, and munitions and residue from range construction or use would remain on ranges to be treated and managed according to applicable DoD Directives, UFC, and the manual titled, “Prevention of Lead Migration and Erosion from Small Arms Ranges” (NAVFAC Pacific EV24SH, personal communication, April 26, 2013). As discussed in Section 5.1.2, Water Resources, there would be no impacts to nearshore waters through implementation of surface water protection measures (i.e., implementation of LID, range maintenance BMPs, pollution prevention plans during operations).

**Marine Flora and Invertebrates**

There would be no in-water training. Given the nominal quantity of bullets that would overshoot the bermed areas to enter the marine environment and the BMPs described above, no direct long-term impacts are expected to occur to marine flora and invertebrates as a result of the operation of the proposed LFTRC at Route 15.

**Fish**

As previously discussed under Marine Flora and Invertebrates, the nominal quantity of bullets that would overshoot the bermed areas to enter the marine environment and implementation of the BMPs described above would result in less than significant direct impacts to fish from LFTRC operational activities.

**Essential Fish Habitat**

As previously discussed under Marine Flora and Invertebrates, the nominal quantity of bullets that would overshoot the bermed areas to enter the marine environment and implementation of the BMPs described above would result in less than significant direct impacts to EFH from LFTRC operational activities. Per the Magnuson-Stevens Fishery Conservation and Management Act, there would be no adverse effect on EFH because construction of the proposed action would not reduce the quality or quantity of EFH with implementation of access restrictions and the Construction General Permit and appropriate construction BMPs.

**Special-Status Species**

No explosive projectiles are proposed for use and all projectiles are expected to be contained within the range footprint by bullet traps or backstops, with the exception of ricochets, which would be contained within the SDZs, according to statistical analysis provided in the 2010 Final EIS. Signage as well as lighting (blinking red lights) would notify people in the area that the ranges are in use. However, the signage and lighting would be designed to insure minimal to negligible impacts on special-status species, primarily sea turtles. Therefore, there would be less than significant direct impacts to special-status species as a result of LFTRC operational activities.

**Marine Conservation Areas**

There are no marine conservation areas in the vicinity of Alternative 1. Therefore, there would be no impacts to such areas.
5.1.10 Cultural Resources

5.1.10.1 Affected Environment

The following discussion summarizes previous cultural resources studies, known historic properties, and other cultural resources within the PDIA and PIIA associated with Alternative 1. The Alternative 1 area, also known as the Route 15 alternative, is situated on the northeast side of the island of Guam. It includes a portion of Andersen South, but the majority of the lands are located just south of Andersen South, separated by Route 15. Current land ownership outside of Andersen South includes the GovGuam, Guam Ancestral Land Commission, Chamorro Land Trust Commission, and private landowners. Historically, some of the area appears to have been part of the U.S. Marine Transient Center in 1946 and was subject to mechanical clearing by 1953.

The affected environment for cultural resources associated with Alternative 1 is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 12: Cultural Resources, Section 12.1.3.1: Andersen South and Section 12.1.3.3: Non-DoD Land, pages 12-20 to 24). This description of the affected environment is updated here with new information from recent archaeological and architectural investigations conducted for this SEIS and other projects. To determine whether site information is from previous investigations (such as the 2010 Final EIS or other cultural resource studies) or prepared during in-fill studies conducted for this SEIS, refer to dates in the reference column in each table for the archaeological sites. Certain information about built properties (such as date and function) was derived from iNFADS.

The majority of the Alternative 1 PDIA and PIIA was surveyed for the presence of cultural resources for the original proposed action (2010 Final EIS). Cultural resource investigations for the Final EIS and other previous investigations included archaeological surveys (Moore 1987; Moore et al. 2002; Moore et al. 2007; Welch 2010; Dixon et al. 2011a), architectural inventories (Yoklavich et al. 1996, Mason Architects 2004; Welch 2010), and TCP studies (Griffin et al. 2010). Additional investigations conducted for this SEIS included intensive cultural resource inventories in the PDIA and reconnaissance inventories in the PIIA (Dixon et al. 2015a, 2015b). Note that portions of the PIIA (60 acres [24.3 ha]) were not inventoried, because of steep topography or a lack of accessibility; however, a previous survey in the area did record one site in the area most likely to contain cultural resources. This information has been incorporated in this analysis. Collectively, these investigations provide the inventory of cultural resources for analysis in Alternative 1.

As described in 5.1.10.1, the HG Range would be located at Andersen South under all of the LFTRC alternatives. This entire area was previously surveyed at an intensive level (Welch 2010; Dixon et al. 2011a).

During October to December 2014, the DON consulted with the parties to the 2011 PA and the public on the Draft TRRA. Consistent with Stipulation V.C of the 2011 PA, the TRRA provided planning level information on potential direct and indirect effects to historic properties within areas that may be selected in the DON’s ROD for the live-fire training range complex. The Draft TRRA included information on the locations, orientations, and designs of each proposed LFTRC location. In addition to receipt of written comments, DON cultural resources professionals conducted three consultation sessions with the parties to the PA to discuss the analysis. The DON will take all comments into account in preparing the Final TRRA, which is planned for publication shortly after this Final SEIS. Comments and considerations developed during the Draft TRRA consultation process have been incorporated in this Final SEIS and informed the Draft RMP, as required by Stipulation V.C.4 of the 2011 PA.
Cultural Resources in the Alternative 1 PDIA

Alternative 1 would involve the construction of individual ranges, support buildings, parking areas, towers, access roads, and the relocation of a portion of Route 15. This construction area comprises the PDIA.

Table 5.1.10-1 lists 10 known archaeological sites located within the Alternative 1 PDIA on Andersen South and the area south of Route 15. Three sites, Pre-Contact/Latte Period ceramic scatters, are eligible for listing in the NRHP. Seven sites are considered ineligible for listing in the NRHP.

Portions of the Alternative 1 PDIA, including the HG Range, are located in Andersen South, where architectural properties are present. Approximately half of the buildings at Andersen South have been assessed for potential NRHP eligibility (Mason 2004; SEARCH 2013; Welch 2010; Yoklavich et al. 1996). Most of the buildings at Andersen South are abandoned housing units that were built in either 1948 or 1978. Other buildings include support facilities built in the 1940s, 1960s and 1980s.

There are 53 architectural properties, constructed between 1945 and 1990, in the PDIA (Table 5.1.10-4). Forty-two of these buildings and structures are part of the Andersen South Housing Development built in 1948 and 1978; all of these buildings are considered not eligible for listing on the NRHP. Other architectural resources include two gatehouses built in 1990 and nine water support facilities that are all considered not eligible for listing in the NRHP.

Notes: Information on type, number, and date of construction from iNFADS.

No TCPs have been identified in the PDIA for this alternative.
Cultural Resources in the Alternative 1 PIIA

The PIIA comprises the area within the SDZs for the LFTRC and HG range and associated areas potentially affected by increases in noise. Table 5.1.10-5 summarizes the eight known archaeological sites located within the Alternative 1 PIIA. Of these 8 sites, 6 are eligible for listing in the NRHP and include 2 ceramic scatters, 2 caves/rock alignments, and Pågat and Pågat Point, a latte complex and an agricultural complex and potential TCP (Griffin et al. 2010). Of the remaining 2 sites, 1 artifact scatter is ineligible for listing in the NRHP and 1 cobble alignment has not been evaluated.

Legend: NRHP = National Register of Historic Places; NA=not applicable; NRHP criterion A = eligible because they are associated with events that have made a significant contribution to the broad pattern of history, criterion D = eligible for potential to yield information important in prehistory or history.

There is one structure located in the PIIA for Alternative 1. It is a water storage tank that was built in 1961. It has not been evaluated for listing in the NRHP. Should this alternative be selected, the structure would be addressed consistent with the procedures outlined in the 2011 PA. One potential TCP, the Pågat Point site, has been identified in the PIIA for this alternative and there is one potential TCP in the vicinity—the Pågat site (site 66-04-0022), which is located adjacent to, but outside of, the area to the westernmost extent of the PIIA.

5.1.10.2 Environmental Consequences

Construction

Construction of Alternative 1 has the potential to adversely affect historic properties and impact culturally important natural resources. Final determinations would follow the procedures in the 2011 PA. Following is a discussion of potential direct and indirect effects to historic properties and impacts to culturally important natural resources.

Construction of the ranges, support facilities, utilities, and relocation of Route 15 would primarily occur in the southeastern portion of Andersen South and the northeastern and central portion of the area south of Route 15 (see Figure 2.5-2). Given the substantial development anticipated in the PDIA, it is assumed for purposes of this analysis that 100% of the PDIA would be disturbed. Nevertheless, design alternatives to avoid and minimize adverse effects would be considered, consistent with procedures in the 2011 PA. No construction is proposed in the PIIA.
Excavation and soil removal associated with the construction of Alternative 1 could adversely affect three historic properties, including Pre-Contact/Latte Period artifact scatters (see Table 5.1.10-1). One of the historic properties is located in both the PDIA and PIIA. Direct impacts to the site would only occur to the portion within the PDIA. Construction associated with Alternative 1 would also require the demolition of 50 buildings and structures (Table 5.1.10-6). None of the buildings and structures are eligible for listing in the NRHP.

*Note: *Map number from Welch 2010 (not a facility number).

Construction activities associated with Alternative 1 would not affect the Pågat Site (site 66-04-0022), which includes Pågat Village and Pågat Cave. Under this alternative, the range complex would be located on the limestone plateau, west and more than 300 feet (91 m) in altitude above the Pågat site, and would not be visible from the site. Consistent with the 2011 PA, access to the Pågat Site would not be affected by construction.

Construction activities associated with Alternative 1 have the potential to directly impact culturally important natural resources. The 2011 PA contains measures for coordinating with the SHPO and concurring parties to contact traditional natural healers, herbal practitioners and traditional artisans regarding identification and disposition of these important resources prior to construction (see 2010 Final EIS, Volume 2: page 2-10; Volume 9, Appendix G, Chapter 4).

No historic properties or culturally important natural resources are anticipated in conjunction with utility upgrades that would be associated with Alternative 1. The modification or replacement of existing overhead electrical lines under Alternative 1 would not affect any known cultural resources. There are no known NRHP-eligible properties or culturally important natural resources located in areas planned for water or wastewater upgrades to support Alternative 1.

There are no historic properties located in the PDIA or PIIA for the proposed HG Range at Andersen South. Therefore, no adverse effects to historic properties are anticipated due to construction of the HG Range.

**Operation**

Operations associated with Alternative 1 could cause indirect adverse effects to historic properties as discussed below. Final determinations of effect would follow the procedures in the 2011 PA. Following is a discussion of potential adverse effects of operations associated with Alternative 1.
The potential for direct effects within the SDZ would be limited to the risk of strikes from stray rounds during Alternative 1 operations. The risk of such effects occurring is extremely low. The range would be designed to contain live fire inside the range itself to minimize the probability of rounds landing in the SDZ. The natural terrain would also serve to prevent direct effects in the SDZ, because the culturally sensitive areas within the Alternative 1 SDZs are substantially lower in elevation than the site of the range. Additionally, if a stray round were to escape the range, the chance of it hitting a historic property is remote, given the size of the SDZ and dispersal of historic properties. For these reasons, the potential for direct adverse effects as a result of range operations is de minimis.

Indirect adverse effects to NRHP-eligible archaeological sites from the operation of Alternative 1 could result from changes affecting site integrity. For many types of archaeological sites (e.g., ceramic scatters, rock alignments), auditory impacts associated with live-fire operations would not affect characteristics that qualify them for the NRHP. An increase in noise associated with live-fire operations may adversely affect historic properties for which solitude, quiet, or contemplation contribute to or define their significance, such as TCPs. Under Alternative 1, small arms live-fire noise would be audible near four NRHP-eligible sites that are located within the expanded noise contours. Average noise levels during range operations are projected to increase from current levels to between 65 dB and 85 dB ADNL (see Section 5.1.4, Noise). Three of the sites are Pre-Contact artifact scatter and a rock alignment, while the remaining site is Pågat Point, a potential TCP. At the Pågat Point site, anticipated noise levels could be over 70 dB ADNL. Auditory impacts associated with range operations would not adversely affect the integrity of the NRHP-eligible artifact scatters and rock alignment. Changes to the setting of the Pågat Point site could be adverse, if the property is confirmed as a TCP. Final determinations of effect would follow the procedures in the 2011 PA. Potential mitigation to reduce noise impacts as discussed in Section 5.1.4, Noise, include the development of a detailed noise reduction plan, which may include maintaining/enhancing dense foliage and/or constructing berms to mitigate noise.

An indirect adverse effect to the Pågat Site (GHPI Number 66-04-0022) from visual intrusions associated with Alternative 1 could result from construction of an observation tower near the cliffline on the plateau above this site. Final design characteristics of the tower, including height and location, would be dependent upon topography and other environmental conditions. Based on the current preliminary concept plan, the tower would be visible from the Pågat Site. The effect to the setting of the Pågat Point site could be adverse. If this alternative is selected, a final determination of effect would follow the procedures in the 2011 PA. Potential mitigation to reduce visual impacts as discussed in Section 5.1.4, Noise, include the development of a detailed noise reduction plan, which may include maintaining/enhancing dense foliage and/or constructing berms to mitigate noise.

Operation of this alternative would not result in restricted access to the Pågat Site (GHPI Number 66-04-0022), which includes Pågat Village and Pågat Cave. Range complex operations under this alternative could lead to increased population in the area, which could increase the risk of inadvertent damage. The 2011 PA includes a provision to provide Cultural Resources Awareness Training to all DoD personnel and contractors in order to lessen the risk. The implementation of BMPs, and the institution of a groundwater monitoring program at the range as described in Section 5.1.2.2, would ensure that the groundwater and freshwater pools at the Pågat site would not be contaminated.

Summary of Impacts and Potential Mitigation Measures

Implementation of Alternative 1 could cause direct, adverse effects to three known NRHP-eligible sites. Potential indirect adverse effects could occur to one NRHP-eligible site/potential TCP within the PIIA from an increase in noise. Indirect adverse effects could occur to one additional archaeological
site/potential TCP (the Pågat site, GHPI Number 66-04-0022) due to an increase in recreational pedestrian traffic and visual intrusion from an observation tower. In addition, culturally important natural resources could be directly impacted due to removal of limestone forest. The 2011 PA includes measures to coordinate with SHPO and concurring parties to address appropriate treatment of these resources.

Under this alternative, adverse effects from construction would be fewer than any of the other LFTRC alternatives. Adverse effects from operation could occur, but would be fewer than any of the other alternatives. Refer to Section 5.7, Table 5.7-1 for a comparison of cultural resources impacts and potential mitigation measures for each LFTRC alternative.

The 2011 PA, as discussed in Section 3.1.2., establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. Broadly, the 2011 PA includes processes to share information, consider views of the public, and develop mitigation measures when historic properties may be adversely affected. The 2011 PA provides measures for mitigating adverse effects to NRHP-eligible or listed archaeological sites, consulting on new projects and initiating additional identification efforts, and resolving impacts due to loss of access to TCPs or culturally important natural resources.

More specifically, the 2011 PA established a process for the review and analysis of potential effects to historic properties and other cultural resources for all alternative LFTRC locations. Beginning in October 2014, the DON consulted with the parties to the PA and the public on the TRRA, which provided information about cultural resources potentially affected by the LFTRC alternatives carried forward in the SEIS, consistent with PA Stipulation V.C.4. The TRRA provides information on potential adverse effects resulting from the construction and operation of the LFTRC alternatives to support consultation with the PA parties and the public. The DON will take all comments into account before reaching a final decision. For any alternative selected in the ROD, the 2011 PA stipulates that an RMP will be prepared to address effects from the construction and operation of the ranges. The RMP, developed in consultation with the consulting parties, will stipulate measures to avoid, minimize, and mitigate adverse effects to historic properties.

To the degree possible, direct and indirect impacts to historic properties and natural resources of cultural importance would be avoided or minimized during the planning process. Consultation under the 2011 PA would address potential adverse effects and alternatives to avoid adverse effects. Refer to Section 3.10 for more information on definitions and procedures. If avoidance is not possible, Table 5.1.10-7 presents potential mitigation measures to resolve adverse effects to historic properties and reduce impacts to cultural resources resulting from the implementation of Alternative 1. With the implementation of these measures and processes as outlined in the 2011 PA, it is expected that significant impacts, as defined under NEPA, could be reduced to a level below significance.

5.1.11 Visual Resources

5.1.11.1 Affected Environment

A list and description of visual resources along Route 15 are provided in the 2010 Final EIS (Volume 2, Chapter 13: Visual Resources, Section 13.1.2.11: Andersen South and Section 13.1.2.2 Non-DoD Land, pages 13-24 to 13-31). Typical views from the Route 15 project area are provided on page 13-26 of the above-referenced section in the 2010 Final EIS. The general visual quality of the area is moderately high, with a moderate vividness, moderately high intactness, and moderately high unity. This visual quality is summarized in Tables 13.1-5 and 13.1-6 of the 2010 Final EIS (Volume 2, Chapter 13: Visual Resources, Section 13.1.2.5: Off-Base Roadways, pages 13-36 to 13-38). The high ratings reflect the forested areas on either side of the roadway.

Alternative 1 includes realigning a portion of Route 15 through Andersen South, as described in the 2010 Final EIS. Approximately two-thirds of this new alignment would cut through the forested area. The remaining one-third would run through an area that once served as military housing, which has since been removed. Old roads and cleared areas remain in this area. Typical views for the project area are shown in Photos 5.1.11-1 and 5.1.11-2.
Environmental Consequences

Construction

During construction, activities and equipment would temporarily cause view obstructions where recognized views currently exist. The direct visual impacts during the construction phase would be short-term and less than significant.

Operation

The impacts on visual resources under Alternative 1 would be the same as those discussed in the 2010 Final EIS (Volume 2, Chapter 13: Visual Resources, Section 13.2.2: Environmental Consequences, pages 13-262 to 13-68). Clearing and grading for rerouting Route 15 and development of the live-fire training range would result in moderate to substantial alteration of the existing landscape. As part of the new road, two highway underpasses would be constructed on the portions of the road extending through Andersen South. Public views would change from a primarily vegetated landscape to cleared views exposing berms...
and existing structures (including roadways, parking areas, fencing, and entry gates). Alternative 1 would require the creation of a relatively large, cleared roadbed and shoulder area inland from the existing road, resulting in a less natural topography and less mature vegetated appearance than currently exists at this location.

As discussed in the 2010 Final EIS, the realignment of Route 15 inland, the need for grading, filling and land clearing, and the need to excavate for the construction of two underpasses would result in the significant alteration of the visual landscape. However, with the exception of a small portion of the new road that would be built on private property at the north end, the majority of the new roadway would traverse DoD property at Andersen South - lands currently not accessible to the general public.

While the visual landscape would be substantially altered during the construction phase, Alternative 1 would not result in significant negative visual impacts. Over time, the graded and replanted areas would blend with the surrounding topography, and eventually, the surrounding vegetative cover as well. The realigned Route 15 would traverse the same type of fast-growing scrub forest areas as those bordering the existing road, and would produce the same type of visual experience as those from the current route. Alternative 1 would have more of an impact to visual resources than Alternatives 2 or 5, but less of an impact than Alternatives 3 and 4, because the long-term visual environment may not result in negative impacts after construction and replanting are complete.

5.1.12 Ground Transportation

5.1.12.1 Affected Environment

The affected environment for ground transportation resources associated with Alternative 1 includes transportation facilities internal to the site (range roadways and intersections). This section discusses existing conditions and assesses how the operations and construction of Alternative 1 would potentially affect transportation conditions for roadways and intersections within the LFTRC site. Impacts to off-base (external) roadways and intersections are summarized in Section 6.1 of this SEIS.

5.1.12.2 Environmental Consequences

Potential ground transportation impacts addressed in this section are limited to elements of the proposed action that could affect roadways internal to the LFTRC site. Potential ground transportation impacts to off-base (external) roadways are addressed in Section 6.1 of this SEIS.

Construction

Potential construction impacts for Alternative 1 would be the same as those described in Section 4.1.12.2 for Alternative A. Potential direct and indirect impacts to ground transportation resources from construction would be minimized with implementation of appropriate work zone traffic management strategies and BMPs. Therefore, there would be less than significant short-term impacts to on-base (internal) roadways.

Operation

Proposed access to Alternative 1 would be from Route 1 through the existing Andersen South access road. An underpass under the relocated Route 15 would allow access to the internal range road network. Alternate access would be via a second underpass under the Route 15 bypass. The proposed access roadway network would avoid an increase in traffic on Route 15 and local roads. Additionally, the location of Route 15 adjacent to the existing Andersen South Training Complex would facilitate transition
from live-fire to non-live fire training and provide maximum efficiency for range maintenance and management.

Active-duty Marine Corps personnel based on Guam would participate in various training courses at the existing Andersen South Training Complex facility and at the proposed LFTRC. Normal range operations require that trainees arrive before 7:00 a.m. and stay until late afternoon. Based on this schedule, trips to the LFTRC would occur prior to the weekday morning peak hour (7:00 a.m. to 8:00 a.m.) and return trips were conservatively modeled as occurring during the weekday afternoon peak hour (4:30 p.m. to 5:30 p.m.).

Transportation of UDP personnel to and from the LFTRC would be provided using passenger buses, as UDP personnel would generally not be expected to have access to POVs. However, permanent party officers and SNCOs would have the option to utilize POVs. Lower-ranked personnel would be required to use GOVs to and from the LFTRC. Support staff assigned to the ranges may commute via POV or GOV. It is assumed that a proportion of permanent party officers and SNCO’s would elect to drive a POV. In addition to transporting personnel, transportation requirements include the movement of equipment and ammunition to the LFTRC via MTVRs. Each range would also be required to have an emergency response vehicle. A summary of daily transportation requirements for the LFTRC by vehicle type is provided in Table 5.1.12-1, and represents the maximum potential adverse effect for traffic.

<td>6</td>
</tr>
</tbody>
</table>

Legend: MTVR = Medium Tactical Vehicle Replacement.
Sources: FHWA 2013a, 2013b.

Approximately 32 privately-owned vehicles, 6 buses and MTVRs, 8 delivery trucks, and 1 emergency vehicle would be added to the roadway network per weekday in support of training activities at the proposed LFTRC. Each vehicle would make two trips: one trip to the training facility during off-peak hours and one return trip during the weekday p.m. peak hour. A summary of the weekday afternoon peak hour LFTRC-related traffic is provided in Table 5.1.12-2.

### Table 5.1.12-2. Marine Corps LFTRC Training Trips - Weekday p.m. Peak Hour

<td>16</td>
</tr>
</tbody>
</table>

Legend: MTVR = Medium Tactical Vehicle Replacement.
Notes: Buses, MTVRs and delivery trucks are assigned a primary constituent element of 3.0 to account for their size and acceleration relative to passenger cars.
Sources: FHWA 2013a, 2013b.

As shown in Table 5.1.12-2, training requirements at the LFTRC would result in the addition of approximately 38 trips (passenger car equivalents) to the roadway network during the weekday afternoon peak hour.

Under any of the proposed LFTRC alternatives, construction of new internal roadway facilities and entry control facilities would be required. The proposed action includes construction of internal roadways and
entry control facilities that would be implemented by the DoD. The internal range roadways and intersections have been designed to accommodate the expected travel demand on the facilities. Specifically, internal range roadway segments and intersections would operate at acceptable LOS (LOS A, B, C, D, or E) under future year (Year 2030) conditions with the proposed action.

The proposed action would not result in a direct, long-term significant impact to internal (range) roadway segments or intersections because the proposed action would not:

- For roadway segments and intersections - cause a roadway segment or intersection operating at acceptable LOS (LOS A, B, C, D, or E) to degrade to unacceptable LOS F.
- For roadway segments - add 5% or more to the total directional peak hour volume (measured in passenger car equivalents) and result in unacceptable LOS F.
- For intersections - add 50 or more peak hour trips (measured in passenger car equivalents) and result in unacceptable LOS F.

For intersections - add 50 or more peak hour trips (measured in passenger car equivalents) and result in unacceptable LOS F.

5.1.13 Marine Transportation

5.1.13.1 Affected Environment

The Route 15 LFTRC alternative location and orientation would result in an SDZ that encompasses an area of approximately 2,805 acres (1,135 ha) of the Pacific Ocean off the southeast coast of Guam. The Alternative 1 SDZ would not cross into a designated shipping lane.

5.1.13.2 Environmental Consequences

Construction for the project takes place on shore with no in-water or coastal components; therefore, there would be no impacts to marine transportation during construction. The area of the SDZ would be closed to all vehicle traffic on an intermittent basis, in accordance with 33 CFR 334, to allow uninterrupted training. The short-term nature of the closure and the location of the SDZ away from marine shipping lanes would result in a less than significant impact on marine transportation during operation of the LFTRC.

In order to ensure that watercraft are not at risk of accidentally entering the SDZ and being struck by projectiles fired from the firing ranges, designated military personnel, trained in the use of sighting equipment, would observe the SDZ and nearby waters for vessel traffic. Two proposed Range Observation Towers would give observers an unobstructed view to survey the SDZ for vessels before and during live-fire exercises. Live-fire training would cease if a vessel entered the SDZ and resume only when the SDZ was cleared. Cessation of live-fire via observer notice would minimize the risk of a vessel being struck by projectiles. The SDZ area would be identified on nautical charts, but would not be physically marked on the ocean surface. Standard operating procedures would be implemented to notify mariners of training activities and ensure that the SDZ is cleared of vessels prior to live-fire training. The direct and indirect short- and long-term impacts would be less than significant.

5.1.14 Utilities

5.1.14.1 Affected Environment

Electrical Power

The electrical utility near Alternative 1 consists of an existing local GPA power distribution system. The existing system is a 13.8 kV overhead distribution line. These distribution lines serve Marbo Booster Pump Station No. 3 and other areas of Andersen South.
The HG Range would be in one location at Andersen South for all LFTRC alternatives. The electrical utility in this area consists of DoD overhead 3-phase 13.8 kV distribution lines, the DoD owned Marbo Substation northeast of the HG Range, and the GPA-owned Marbo Combustion Turbine, which is adjacent to the Marbo Substation. The combustion turbine has not been used in approximately 10 years. The substation is operating, but typically unoccupied. These items are within a security fence.

**Potable Water**

The potable water system near Alternative 1 includes elements of the DoD water transmission and distribution system. This existing functioning system consists of underground water lines, manholes, Marbo Booster Pump Station No. 3, and Marbo Tank No. 4 (460,000 gallons [1,741,289 liters]). The DoD water distribution system at the Andersen South abandoned housing area was also abandoned. Due to elapsed time and lack of use and maintenance, this distribution system within the Andersen South abandoned housing area is deemed unusable and unsalvageable. There is a water main on the road to the former Andersen South housing area from Route 1 to the north, but it is capped at the point of entrance to Andersen South. The GWA has an existing active water line along Route 15.

The HG Range would be in one location at Andersen South for all LFTRC alternatives. There is a raw water line buried in the east/west road to the north of the proposed location of the HG Range. This line collects water from existing groundwater production wells. There are also fire hydrants along that same road. There are no potable water lines near the HG Range.

**Wastewater**

There is currently no wastewater collection system within the specific Alternative 1 area limits, including the location for the HG Range.

The HG Range would be in one location at Andersen South for all LFTRC alternatives. The closest available operating sewer line for Alternative 1 is to the north along Route 1 and is a GWA asset.

**Solid Waste**

There are no solid waste facilities near Alternative 1.

The HG Range would be in one location at Andersen South for all LFTRC alternatives. There are no solid waste facilities near the HG Range.

**Information Technology and Communications**

There is no DoD IT/COMM infrastructure near Alternative 1. There may be commercial IT/COMM routing lines near this alternative, most likely along Route 15.

The HG Range would be in one location at Andersen South for all LFTRC alternatives. There is no DoD IT/COMM infrastructure near the HG Range. Also, there are no known IT/COMM commercial utilities near the HG Range.

5.1.14.2 Environmental Consequences

**Electrical Power**

There are electrical power system elements along Route 15 within Alternative 1 that would require relocation along with the rerouting of Route 15. This would have direct, short-term impacts on current customers consisting of potential limited power outages during construction. Power outages would be addressed through construction phasing or the use of temporary generators where necessary, which would minimize downtime. The electrical power requirements of the LFTRC facilities would be small (less than
50kW), and thus would have limited impact on the current system or current power customers. The proposed electrical improvements for Alternative 1, as described in Sections 2.5.4.1 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action.

The HG Range would be in one location at Andersen South for all LFTRC alternatives. The power demand from the HG Range would be minimal, so there would be a less than significant direct, long-term impact on the system or current power customers.

The short- and long-term direct impact associated with LFTRC Alternative 1 on the electrical utility would be less than significant, both during construction and in operation.

**Potable Water**

The proposed water system improvements for Alternative 1 as described in Chapter 2 of this SEIS (for the HG Range) have been developed to meet the requirements for the proposed action. The Range Maintenance Building and the KD Rifle/KD Pistol Range Administrative Building are the only LFTRC facilities requiring water service. A fire hydrant would also be provided for filling range fire fighting vehicles and general fire protection. The potable water demand of the LFTRC would be very small, estimated at an average daily demand of 26,520 gallons per day (100,389 liters per day). Therefore, a less than significant direct, long-term impact on the current DoD water system would occur.

The GWA existing active water line running along Route 15 would need to be realigned with Route 15 construction. Construction practices would be utilized to minimize short-term, direct impacts to the users of this water line. Users could experience short-term water outages as the new routing is switched over to the existing routing. This section of water line would then be new, providing long-term benefit over the current condition of the existing line.

The HG Range does not require water service and there are existing fire hydrants nearby at the Andersen South location. There would be no impact on the potable water resource for this range.

Therefore, short- and long-term, direct impacts associated with Alternative 1 to the potable water utility would be less than significant, both during construction and in operation.

**Wastewater**

The proposed wastewater collection system improvements for Alternative 1, as described in Sections 2.5.4.1 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The only LFTRC facility requiring sewer service would be the Range Maintenance Building and the KD Rifle/KD Pistol Range Administrative Building that have an estimated wastewater flow of less than 0.01 MGd (0.038 MLd). A new sewer line would be installed and tied into the existing GWA sewer line along Route 1. The estimated sewer flow demand is minimal and would be a less than significant long-term, direct impact. During construction, short-term service outages could occur while the new sewer line is tied into the existing sewer line. With careful planning these potential outages would be minimized. All other LFTRC facilities, including the HG Range, would be provided with portable toilets. These toilets would require periodic emptying, with the sewage then being taken to one of the existing WWTPs for treatment and disposal. The estimated sewage amount is minimal and would not impact the current wastewater resource.

Therefore, short- and long-term, direct impacts associated with Alternative 1 to the wastewater utility would be less than significant both, during construction and in operation.
Solid Waste

The proposed solid waste improvements for Alternative 1, as described in Sections 2.5.4.1 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The estimated long-term solid waste generation for LFTRC operations is minimal, and this additional solid waste would not impact current waste collection, handling, or disposal operations. Suitable solid waste collection containers would be provided within the LFTRC, where required. The solid waste would be periodically collected, handled, and transported to the main cantonment transfer station.

There would be a short-term, direct impact to the solid waste handling effort during the utilities and site improvements (U&SI) construction involving the generation of green waste from clearing and grubbing the range areas and roads, as well as the generation of C&D debris waste. The DON updated the Final Comprehensive Construction and Demolition and Solid Waste Management Plan for Guam Military Relocation, including the green waste management sections. The Utilities and Site Improvement (U&SI) contractor would be required to process/compost green waste on-site. As part of construction waste management, contractors would be required to submit a green waste processing/composting plan to the DON and obtain required solid waste permits for green waste processing and composting from GEPA. The DON would review the contractors’ project-specific waste management plans prior to their submittal to GEPA and would provide oversight during the construction. C&D debris generated during the buildup would be handled by the U&SI contractors at a designated laydown area. The U&SI contractor would be required to divert all the green waste and a minimum 60% of the C&D debris from disposal. The larger-sized green waste consisting of trees and stumps would be processed into mulch and the smaller-sized green waste would be processed into compost. The C&D debris would mainly consist of concrete that would be crushed and used as lower-graded aggregate. Construction and demolition debris would be processed for reuse or disposed in permitted facilities in accordance with all regulatory requirements, EOs, and DoD requirements.

The DON proposes to explore ways to resolve key solid waste issues, specifically the status of the Naval Base Guam Landfill permit and handling of special wastes not accepted at Layon Landfill, through the Solid Waste Working Group that was established with USEPA and GEPA on July 24, 2014. During the September 19, 2014 meeting of the Solid Waste Working Group, GEPA indicated that they will formally respond to DON correspondence with regards to issues relative to the Naval Base Guam Landfill. The Layon Landfill and the permitted private hardfill facilities are operating within their regulatory requirements. The proposed action would be in compliance with all applicable GEPA solid waste permit terms and conditions that routinely include specific measures to protect human health and the environment. All other projects on Guam would utilize permitted solid waste management and disposal facilities. The Layon Landfill and the permitted private hardfill facilities are operating within their regulatory requirements. The proposed action would be in compliance with all applicable GEPA solid waste permit terms and conditions that routinely include specific measures to protect human health and the environment. All other projects on Guam would utilize permitted solid waste management and disposal facilities.

Therefore, short- and long-term, direct impacts associated with LFTRC Alternative 1 to the solid waste utility would be less than significant, both during construction and in operations.

Information Technology and Communications

The proposed IT/COMM infrastructure for Alternative 1, as described in Section 2.6, has been developed to meet the requirements for the proposed action. Because there are no existing IT/COMM resources near this LFTRC alternative, there would be no impacts to existing IT/COMM services. There would be inter-
base connectivity required for DoD IT/COMM, as discussed in Section 2.6. Installation of these IT/COMM lines could cause temporary service disruptions to current IT/COMM users, but would be for minimal time durations. New duct banks for Alternative 1 that would be installed include a duct bank of six 4-inch (10-cm) conduits interconnecting the LFTRC range facilities, including the HG Range.

Therefore, short- and long-term direct impacts associated with Alternative 1 to the IT/COMM utility would be less than significant, both during construction and in operation.

5.1.15 Socioeconomics and General Services

Most issues and impacts associated with socioeconomics encompass the entire proposed action (i.e., cantonment/family housing and LFTRC development, increased population), and do not vary with site alternatives. Accordingly, the impact discussion in Section 4.1.15 of this SEIS applies for all of the LFTRC alternatives and is incorporated here by reference. Land acquisition, however, is unique to the LFTRC alternatives, and the amount of land to be acquired varies by alternative. Therefore, this section focuses exclusively on the socioeconomic and sociocultural impacts associated with land acquisition under Alternative 1 (with the exception of the HG Range, which would not require land acquisition).

5.1.15.1 Affected Environment

Table 5.1.15-1 shows baseline data for land that would be acquired for the Route 15 LFTRC alternative. A total of 896 acres (362.6 ha) of land would be acquired by the federal government. Most of the land (676 acres, 273.6 ha) is currently managed by the CLTC and an additional 197 acres (80 ha) are managed by the GALC. The remaining 23 acres (9.3 ha) are owned by GovGuam. No privately-owned land would be acquired under Alternative 1.

Table 5.1.15-2 shows existing land use in the Route 15 acquisition area. Land use on the Route 15 parcel is primarily undeveloped in a natural state (73.2%). The developed site raceway park (14%), quarrying resource extraction use, and pre-development site clearing (3.4%) make up most of the remainder. Approximately 13 acres (5.2 ha) are currently used as a road corridor and 3 acres (1.2 ha) are used for subsistence family agriculture.

Information in Table 5.1.15-3 was provided by GBSP. It shows that the U.S. federal government owns 35,939 acres (14,544 ha) of land on Guam which is approximately 27% of total land on Guam. The DoD has custody and control of most of the federal lands, but there are approximately 1,100 acres (445 ha) of federal land under the custody and control of other agencies, including the NPS, U.S. Postal Service, and the National Weather Service.

The CLTC has provided a commercial license to the Guam International Raceway Park for a term of 20 years, beginning in 1998, to operate on CLTC land. Table 5.1.15-5 shows the rent schedule for the raceway park. During the years 2015 through 2018, the portion of the term of the lease that would coincide with the proposed action, GovGuam is scheduled to earn approximately $192,000.

The Raceway Park also operates a coral quarry and shares 50% of the profits with the CLTC. Based on information in the CLTC Performance Audit published in 2005, quarry operations provide the CLTC with approximately $70,000 per year. Over the 2015 to 2018 period that remains on the lease, which would coincide with the timing of the proposed action, GovGuam is scheduled to earn approximately $280,000 in association with quarrying revenues.

5.1.15.2 Environmental Consequences

The DON is required to comply with federal land acquisition laws and regulations, which include the requirement to offer just compensation to the owner, to provide relocation assistance services and benefits to eligible displaced persons, to treat all owners in a fair and consistent manner, and to attempt first, in all instances, acquisition through negotiated purchase.

The Uniform Relocation Assistance and Real Property Acquisition Policies for Federal and Federally Assisted Programs Act of 1970 (hereinafter the “Uniform Act”), as amended and as enacted through P.L. 91-646, is an important policy that applies to anyone affected by proposed federal land acquisition. This Act provides minimum standards of performance for all federally funded projects that require the acquisition of real property, including the relocation of persons displaced by such acquisition. By law, the federal government is required to offer property owners “just compensation” for their property, which is based on “fair market value” of the property. Fair market value is determined through a federal real property valuation appraisal. The estimated fair market value is used as the basis for acquiring estimates of just compensation. An estimate of just compensation must be established before any property negotiations begin.

Any acquiring agency wishing to begin the process of property appraisal is required to first inform the public. Property owners must be notified that their property is under consideration for acquisition, advised of their legal protections during the process, and invited to accompany the property inspection by an appraiser. This is the initial opportunity for property owners to begin a dialogue with the acquiring agency whereby the owner can confirm ownership and other interests in the property, point out unique amenities, and identify improvements.

Sometimes acquiring agencies do not require the acquisition of entire properties. This is referred to as a partial acquisition. If a partial acquisition creates an “uneconomic remnant,” the agency is required to offer to purchase those remnants. In addition, if partial acquisitions cause damages to remaining properties, amounts offered as compensation should include, as a separate line item, compensation for the damages to the remaining property.

Once negotiations have been completed, a property owner is not required to surrender the property until the agreed purchase price is paid by the acquiring agency. Only exceptional cases warrant right-of-entry for the agency prior to making payment, and only upon approval of the owner.

In addition to paying fair market value, the Uniform Act prescribes certain benefits for eligible occupants impacted by federal property acquisitions, including assistance in finding acceptable replacement housing.
or business location; the payment of moving and other incidental and miscellaneous expenses; and, as needed, certain supplemental payments for increased housing or rental costs at a replacement location.

While the government is authorized to acquire property through its powers of eminent domain (condemnation), it has been the consistent policy of the DON to acquire real estate through negotiation with owners. Even with a negotiated sale or lease however, “friendly” condemnation may be necessary to clear problems with title. The DON would comply with all applicable laws and regulations, including the Uniform Act.

In general, assuming voluntary sale or lease of property and conformance with land acquisition BMPs, land acquisition impacts from both a socioeconomic and sociocultural perspective would not be considered significant. Should condemnation be necessary as a last resort, while the landowner would be made economically whole by payment of fair market value, such an occurrence could represent an adverse sociocultural impact for that individual landowner. Such instances are expected to be extremely rare or nonexistent during implementation of this proposed action, and collectively would not represent a significant impact.

**Socioeconomic and Sociocultural Impacts**

Potential impacts associated with land acquisition could affect individual property owners, occupants, the surrounding community, and GovGuam. Economic impacts presented in this section are total impacts, so they include impacts that would be generated by the proposed action both directly and indirectly. Individual owners and occupants might be impacted from an economic perspective or a sociocultural perspective. Economic impacts associated with land acquisition are those that are purely financial. Sociocultural impacts associated with land acquisition are less tangible and are presented broadly in this section under the assumption that conceptual frameworks such as social disarticulation and cultural marginalization (the deterioration of social structures, networks, or belief systems), and social and psychological marginalization, and stress and anxiety (a person’s loss of confidence in society and themselves, feelings of injustice, and reduced social status) are valid (see Appendix D, Section 5.2.2 for more detail).

**Individual Owner/Occupants**

None of the potentially acquired lots at Alternative 1 are privately owned.

Guam International Racing Federation, a CLTC licensee, operates a raceway park that would be affected by land acquisition associated with Alternative 1. If the lease and license are still current at the time of acquisition, the raceway park land use would not be compatible with uses associated with the proposed action. Also, the acquisition of the Route 15 parcel would impact quarrying operations currently operating on those lands, which would be difficult to relocate due to the specific geological requirements associated with quarry operations.

With regard to sociocultural impacts, this alternative would require the acquisition of seven separate lots, all of which are owned by government entities (GovGuam, GALC, and CLTC). Of the lots required, none are privately owned.

**Community**

Recreation sites within the vicinity of the Route 15 parcel include Guam International Raceway, Marbo Cave, Pågat Trail, Pågat Cave and Village (and Cultural Site), and Taguan Trail. While the revised SDZ avoids direct impacts to Pågat Village and Pågat Cave, there are still potential indirect impacts from firing range noise that could lessen visitor enjoyment of these recreational resources. Also, the Route 15 LFTRC
alternative has been designed to avoid impacting Pågat Village, Cave, and Trail, primarily through the redesigned and reduced footprint for the SDZ both on land and over water.

The Route 15 parcel is classified for agricultural use. However, there are no designated prime farmlands (i.e., lands which are best suited and available for growing crops). Therefore, there would be no impact to agriculture from the loss of prime farmlands.

With regard to sociocultural impacts, the addition of an estimated 896 acres (362.6 ha) of federal land on Guam would be considered by some citizens to be an adverse impact due to the current extent of federal land that is under DoD custody and control (approximately 25.9% of all land on Guam, see Table 5.1.15-3), which would increase to 26.5% with acquisition of the Route 15 parcel. However, because of the DON’s commitment to the concept of “net negative,” by the end of the Marine Corps relocation there would be no net increase in federal land under the custody and control of the DoD.

Implementation of this alternative would require the closure of Guam International Raceway, resulting in significant direct long-term impacts to recreational resources and less than significant indirect long-term economic impacts related to a potential reduction in tourism. There would also be adverse indirect long-term impacts from a sociocultural perspective due to the potential for the loss of the raceway park to deteriorate social networks. Because groups of people currently use the raceway park for social gatherings, if these gatherings at the raceway park ceased then the related social networks may lose cohesiveness.

*Government of Guam*

If there is land acquisition of the Route 15 parcel and the Raceway Park license fees are lost, CLTC would stand to lose $192,000 from 2015 to 2018. In addition, if coral quarry operations also ceased in 2015 due to land acquisition, the CLTC would lose a projected profit sharing revenue of $280,000 from 2015 to 2018, based on past revenue stream. Total lost income to the CLTC (between 2015 and 2018), combining lost Raceway license fees and lost profit share from coral quarry operations is a projected $472,000. Because the land acquisition process would compensate for highest and best use, there would be no impact to GovGuam associated with this loss of revenue.

5.1.16 Hazardous Materials and Waste

5.1.16.1 Affected Environment

The ROI for hazardous materials and waste includes the Air Force and privately-owned properties proposed for development of the LFTRC. Air Force properties include Andersen South and privately-owned lands located east of Route 15 between Pågat Cave and AAFB.

Hazardous Materials Management

*Route 15 Site*

A Phase I Environmental Site Assessment was performed on the site (see hazardous waste management discussion below) and no other potential sources of hazardous materials were in any of the databases searched within the ASTM-specified search distances. However, hazardous materials, predominantly

---

8 “Net negative” refers to the February 7, 2011 commitment by the Under Secretary of the Navy that the DoD would have a smaller footprint on Guam at the end of the Marine Corps realignment process (Under Secretary of the Navy 2011).
POLs, are anticipated to be present at the raceway. No underground storage tanks are known to occur on the site.

Andersen South Hand Grenade Range

No hazardous materials are known to be stored in the area of Andersen South proposed for development of the HG Range under this alternative.

Hazardous Waste Management

Route 15 Site

No recognized environmental conditions were identified on the site in the Phase I Environmental Site Assessment report. However, AAFB is a current National Priorities List site. Andersen South, Marbo Annex is part of the AAFB National Priorities List site and is located on one of the northwest adjacent properties. Because this site is a current National Priorities List site and portions of the site are within 1.0 mile (1.6 km) of the subject property, additional investigations have been conducted and have determined that this site has not impacted the Route 15 property (Air Force 2009).

Limited amounts of hazardous waste, predominantly POLs, are anticipated to be present at the raceway due to the nature of the activities conducted there.

Andersen South Hand Grenade Range

The affected environment at Andersen South with regards to hazardous waste management would be the same as described in Section 3.16.1 of this SEIS. No hazardous materials storage or hazardous waste accumulation areas are located in the area of Andersen South proposed for development of the HG Range.

Contaminated Sites

Route 15 Site

Two Areas of Concern (AOC) (AOC 46 and AOC 47) were identified within the vicinity of the Route 15 property and are attributed to AAFB (Figure 5.1.16-1).

AOC 46 is the former location of vehicle batteries. AOC 47 was a number of separate locations where uncontrolled surface dumping occurred including: automobiles, household debris, household appliances, metal debris, electronic equipment, and a soil pile. These sites have been determined to have no effect on the Route 15 property (Air Force 2009).

Additional areas of contamination may be present at the raceway as a result of leaks and spills of POLs during raceway activities (NAVFAC Pacific 2010a).

Andersen South Hand Grenade Range

There are several IRP sites and AOCs located on Andersen South. However, because the development of the HG Range would impact a relatively small area, only one AOC, AOC-64 - SWMU 42C Battery Shop, has the potential to be affected (Figure 5.1.16-1). This active site is associated with the Marbo Power Plant and is described in detail in the 2010 Final EIS (Volume 9: Appendices, Appendix G: EIS Resource Technical Appendix, Chapter 3: Hazardous Materials and Waste Resources, Table 3.6-22 Summary of Applicable SWMUs and AOC Sites on AAFB, page G-3-38 to G-3-43).

Toxic Substances

Route 15 Site

There are numerous structures located on the Route 15 site that may be affected by the proposed development of Alternative 1. Any structure constructed prior to 1978 may contain LBP, ACM and PCBs.

Andersen South Hand Grenade Range

The proposed HG Range would include an approximately 1.0 acre (0.4 ha) area that would be developed as an HG training complex for the M67 fragmentation hand grenade. An additional 1.0 acre (0.4 ha) training area would be developed adjacent to the range. The area proposed for development of the LFTRC does not appear to contain any structures. Therefore, LBP, ACM, and PCBs are not likely to be present.

Radon

According to the USEPA, Alternative 1 is located in an area classified as Zone 1 for Radon, indicating average indoor radon levels of greater than 4 pCi/L.

5.1.16.2 Environmental Consequences

Construction

Hazardous Materials and Waste

Construction activities would result in a short-term increase in the use of hazardous materials and generation of hazardous waste that would cease at the completion of construction activity. The majority of the hazardous materials expected to be used are common to construction and include diesel fuel, gasoline, and propane to fuel the construction equipment; hydraulic fluids, oils, and lubricants; welding gases; paints; solvents; adhesives; and batteries. However, the increase in hazardous materials would be handled and waste disposed per the applicable BMPs and SOPs identified in the 2010 Final EIS. Adherence with applicable BMPs and SOPs would reduce the likelihood and volume of accidental releases, allow for accelerated spill response times and enable timely implementation of cleanup measures, thereby minimizing potential impacts to the environment. Therefore, the increase in volume would result in less than significant impacts (see Volume 2, Chapter 17: Hazardous Materials and Waste, Section 17.2.2 Alternative 1, Table 17.2-3: Summary of BMPs and SOPs, pages 17-141 to 17-43 and Volume 7, Chapter 2: Overview of Best Management Practices and Proposed Mitigation Measures, Section 2.1: Best Management Practices on Guam and Tinian, Table 2.1-1. Summary of Key Best Management Practices [Guam and Tinian], pages 2-4 to 2-23). Adherence to applicable BMPs and SOPs (e.g., erosion control, routine inspections, employee training) would reduce the likelihood and volume of accidental releases, allow for accelerated spill response times and enable timely implementation of cleanup measures, thereby minimizing potential impacts to the environment.

Should there be a need to import off-island earthen materials, all GEPA, Department of Agriculture, and local rules and regulations would be followed.

Construction and demolition contractors would be required to comply with all applicable requirements concerning handling of construction-related hazardous substances. Hazardous materials associated with construction activities would be delivered and stored in a manner that would prevent these materials from leaking, spilling, and potentially polluting soils, ground and surface waters in accordance with applicable federal, state, and local regulations. Public transportation routes would be utilized for the conveyance of hazardous materials to the construction site. Transportation of all materials would be conducted in
compliance with the Department of Transportation regulations. Therefore, less than significant direct or indirect impacts would occur from the short-term increase in the use, transport, storage and handling of hazardous materials and waste during construction.

Construction and demolition activities associated with this alternative would have no long-term impact on the management of hazardous materials at DoD facilities on Guam. Hazardous materials would continue to be managed under established hazardous material SOPs.

**Contaminated Sites**

Contaminated sites identified under this alternative were determined to either be outside of the proposed construction area and would have no impact on-site conditions, or have been investigated and determined to pose no risk to human health or environmental receptors. Therefore, there would be no direct or indirect impact to IRP/MMRP sites under this alternative during construction.

**Toxic Substances**

There are numerous structures located on the Route 15 site that may be affected by the proposed development of this LFTRC alternative. Any structure constructed prior to 1978 may contain LBP, ACM, and PCBs. Any facility known or suspected to contain LBP, ACM, and PCBs would be properly surveyed, handled, and materials disposed of in accordance with existing laws and regulations, to ensure there would be less than significant direct or indirect impacts to human health and the environment.

Because the proposed construction areas are located in a USEPA Radon Zone 1, it is possible that new buildings, facilities, and structures could encounter radon intrusion. To minimize this impact, radon resistant construction techniques and abatement systems would be incorporated into the building/facility designs. Therefore, less than significant direct or indirect impacts would occur during construction or operations.

**Operation**

**Hazardous Materials**

Live-fire training ranges would experience a long-term increase in the use of hazardous materials from expended training materials resulting from proposed new training. Amounts of expended training materials would increase in rough proportion to the overall increases in these training operations. Activities associated with firing range operations would result in increased hazardous materials in the form of heavy metals. Furthermore, firing range activities would require the use of military transport vehicles and hence a long-term increase in the usage of fuels and POL. It is estimated that firing range operations would result in a long-term increase to the Guam hazardous material disposal rate (2% of the known rate from Marine Corps training on Okinawa), or approximately 640 pounds (290 kg) annually (DRMO Okinawa 2009). For purposes of the impact analysis, it was assumed that the increased volumes of hazardous materials that were considered in the 2010 Final EIS analysis would be reduced because of the generally reduced amount of range operations required for the downsized personnel relocation reflected in this SEIS. The overall reduction in increased use of hazardous materials from range operations under the SEIS alternatives, as compared to the 2010 Final EIS, would be dependent on a variety of factors and cannot be quantified based on available information. Although reduced relative to the 2010 Final EIS volumes of hazardous materials, range operations under Alternative 1 would still represent a substantial long-term increase in the volumes of hazardous material relative to baseline conditions.
Depleted uranium munitions would not be utilized for live-fire training. MCs, in particular heavy metals (lead, nickel, chromium, cadmium, and copper), tend to accumulate in surface soils because of their generally low solubility and their elemental nature. They may oxidize or otherwise react with natural substances, but do not break down in the manner of organic compounds. Therefore, the volume of expended material within the training areas may gradually increase over time (NAVFAC Pacific 2008).

The training range areas under this alternative have limited natural surface waters (see Section 5.1.2, Water Resources). However, range operations under Alternative 1 have the potential to leach MCs to the groundwater. To minimize this potential, range management BMPs would be implemented, as listed in Section 2.8 of this SEIS. As indicated in the 2010 Final EIS, the Route 15 project area overlies the Mangilao Basin and a small portion of the Yigo Basin of the NGLA. Because the NGLA is used as the sole source for drinking water, prior to the construction of the range, site inspection and design/construction information, data from the site survey (preceded by installation of four wells at the NWF LFTRC with associated groundwater sampling and aquifer testing as needed), as well as actual munitions loading data will be provided to the REVA and ORC programs.

The site specific data will be used by those programs to determine the frequency of monitoring and range clearance. For the REVA Program, the site specific data will be used to evaluate the potential impacts to reach potential receptors. This will allow the REVA program to determine whether follow-on actions are required (example: sampling, additional studies, etc.) and the frequency of any further evaluations. REVA will use conservative assumptions and site specific data as available to determine if modeling can be performed for lead components. Monitoring of the ranges for MCs migrating off-range will be based on the outcome of the assessment that is conducted at a minimum every 5 years. The ORC program not only considers the site specific data and REVA data, but also safety and sustainability considerations in their assessments to determine the frequency of range clearance.

Munitions constituents associated with small arms ammunition commonly used at operational ranges include lead, antimony, copper, and zinc. Lead is the primary munitions constituent indicator for small arms ranges because lead is the most prevalent (by weight) constituent associated with small arms ammunition. No specific quantitative conclusions can be made regarding the fate and transport of lead, because lead is geochemically specific regarding its mobility in the environment. Site-specific conditions are required (i.e., geochemical properties) in order to quantitatively assess lead migration. Site-specific geochemical properties are only identified via sampling and cannot be observed physically. Without site-specific physical and chemical characterization, lead cannot effectively be modeled using fate and transport modeling. The scientific community has established that metallic lead (such as recently fired, un-weathered bullets and shot) generally has low chemical reactivity and low solubility in water and is relatively inactive in the environment under most ambient or everyday conditions. However, a portion of lead deposited on a range may become environmentally active if the right combination of conditions exists.

As indicated in the above paragraphs, a site inspection and site assessment will be completed at the range and the site specific information provided to the REVA Manager. The REVA manager will utilize this site-specific information in their assessments of the range, which begin the first year of range operation. Assessing small arms ranges first involves defining and documenting its physical and environmental conditions, as well as how the range is utilized and maintained. The assessment process involves a review of possible factors that can influence the potential for lead to migrate off range including range use and management (source), surface water, groundwater and soil conditions, pathways and receptors (including but not limited to people, sensitive and endangered species). Upon review, if factors or a combination of
factors are found to exist that would indicate possible lead migration, REVA program managers consider sampling appropriate media, identifying and implementing BMPs adjustments or taking other steps as required.

The LFTRC and HG Range would be managed in accordance with current Marine Corps range management policies and procedures, which are designed to ensure the safe, efficient, effective, and environmentally sustainable use of the range area. A thorough explanation of Marine Corps range management is detailed in the 2010 Final EIS (Volume 2, Chapter 2: Description of Proposed Action and Alternatives, Section 2.3.1.4: Firing General Military Skills, pages 2-55 to 2-59). The same range service, maintenance, and environmental protection activities presented in the 2010 Final EIS would be applied to the LFTRC and HG Range proposed in this SEIS. Therefore, operational activities associated with this alternative would have no long-term direct or indirect impact on the management of hazardous materials at DoD facilities on Guam.

Hazardous Waste

Military munitions used for their “intended purposes” at an active range are exempt from RCRA regulation per the MMRP (40 CFR 266.202). In general, military munitions become subject to RCRA treatment, transportation, storage, and disposal requirements as solid/hazardous waste when:

- Transported off-range for treatment, storage or disposal.
- Reclaimed and/or treated prior to disposal.
- Buried or land filled on- or off-range.
- Munitions land off-range and are not immediately rendered safe or retrieved.

As long as the proposed firing ranges on Guam remain on “active” or “inactive” status, the MEC on those ranges would be subject to RCRA regulation only if it is “disposed of” by burial on-range or transported off-range for treatment or disposal. Therefore, as long as this range remains “active” or “inactive” only the disposal of MEC associated with range management would contribute to increased hazardous waste volumes.

MEC at closed ranges are classified as solid waste and would likely be hazardous waste. If determined to be hazardous waste the MEC would be classified as a Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) hazardous substance and subject to remediation requirements. If removed from the range, MEC would also be subject to Resource Conservation and Recovery Act Subtitle C hazardous waste disposal requirements. MEC would be disposed of at AAFB, which holds a Guam RCRA Operating Permit for a hazardous waste management treatment facility at the extreme reach of Tarague Beach. The hazardous waste management facility is permitted to conduct open burning and open detonation to treat MEC that is either reactive (D003) or toxic as defined by the USEPA. The facility is known as the EOD Range. The Facility Identification Number is GU6571999519 and the Permit Number is GUS002. According to Section II.J of the RCRA Permit, the facility may accept wastes from off-site sources and must use Incident Form 3265 to document and track off-site shipments. In addition to increased MEC, there may be slightly increased generation of hazardous waste as a result of expanded firing range operations. Specific increases in hazardous waste generated could include: pesticides, herbicides, solvents, corrosive or toxic liquids, and aerosols primarily used for firing range maintenance and vehicle maintenance. The 2010 Final EIS (Volume 2, Chapter 17: Hazardous Materials and Waste, Section 17.2.2.2 Training Operations, page 17-252) estimated that firing range operations would result in an increase to the Guam hazardous waste disposal rate of 2% of the known Okinawa rate, or approximately 12,880 pounds (5,842 kg) annually (DRMO Okinawa 2009).
For purposes of the impact analysis, it was assumed that the increased volumes of hazardous wastes that were considered in the 2010 Final EIS analysis would be reduced because of the generally reduced amount of range operations required for the downsized personnel relocation reflected in this SEIS. The overall reduction in increased generation of hazardous wastes from range operations under the SEIS alternatives, as compared to the 2010 Final EIS, would be dependent on a variety of factors and cannot be quantified based on available information. Although reduced relative to the 2010 Final EIS volumes of hazardous wastes, operations under Alternative 1 would still represent and substantial increase in the volumes of hazardous waste relative to baseline conditions. To accommodate the increase in hazardous waste generation, an undetermined number of satellite accumulation sites would be created on DoD property, as needed, in proximity to hazardous waste generation. These areas would be managed in accordance with applicable regulations and the facility Hazardous Waste Management Plan to minimize the likelihood of accidental releases and resulting impacts.

Due to the projected increase in the volume of hazardous waste, this alternative would have the potential to result in impacts to human health and the environment (i.e., soils, surface water, groundwater, air, biota). However, the increase in hazardous waste would be handled and disposed per applicable BMPs and SOPs, and therefore the increase in volume would result in less than significant impacts (see Volume 2, Chapter 17: Hazardous Materials and Waste, Section 17.2.2 Alternative 1, Table 17.2-3: Summary of BMPs and SOPs, pages 17-41 to 17-43 and Volume 7, Chapter 2: Overview of Best Management Practices and Proposed Mitigation Measures, Section 2.1: Best Management Practices on Guam and Tinian, Table 2.1-1. Summary of Key Best Management Practices [Guam and Tinian], pages 2-4 to 2-23). Adherence to applicable BMPs and SOPs (e.g., erosion control, routine inspections, employee training) would reduce the likelihood and volume of accidental releases, allow for accelerated spill response times and enable timely implementation of cleanup measures, thereby minimizing potential direct or indirect impacts to the environment. Therefore, impacts would be less than significant.

Contaminated Sites

Contaminated sites identified under this alternative were determined to either be outside of the proposed LFTRC area and would have no impact on-site conditions, or have been investigated and determined to pose no risk to human health or environmental receptors. Therefore, there would be no direct or indirect impact to IRP/MMRP sites under this alternative during operations.

Toxic Substances

Because the proposed LFTRC areas are located in a USEPA Radon Zone 1, DoD would periodically test facilities constructed in known radon zones to verify that no unacceptable radon gas buildup occurs, and would install radon abatement systems as appropriate. Therefore, less than significant direct or indirect impacts would occur during operations.

5.1.17 Public Health and Safety

5.1.17.1 Affected Environment

Operational Safety

The affected environment and potential impacts on public health and safety related to the establishment and operation of an LFTRC on Guam include operational safety, environmental health effects (i.e., noise, water quality), hazardous substances, UXO, and transportation. An extensive discussion of the affected environment for public health and safety matters on Guam is provided in the 2010 Final EIS (Volume 2, Chapter 18: Public Health and Safety, Section 18.1: Affected Environment, pages 18-1 to 18-12).
The Marine Corps practices Operational Risk Management as outlined in OPNAVINST 3500.39A/MCO 3500.27A. Requirements in these documents provide a process to maintain readiness in peacetime and achieve success in combat while safeguarding people and resources. The health and safety analysis presented in the following sections addresses issues related to the health and well-being of military personnel and civilians living on Guam in the vicinity of proposed military operations and training areas.

Andersen South open fields and wooded areas are used periodically for basic ground maneuver training including routine training exercises, camp/tent setup, survival skills, land navigation, day/night tactical maneuvers and patrols, blank munitions and pyrotechnics firing, treatment and evaluation of casualties, fire safety, weapons security training, perimeter defense/security, and field equipment training. Vacant single-family housing and vacant dormitories are used for military operations on urban terrain training and small-unit tactics in support of vehicle and foot-based maneuver training. Activities are conducted in accordance with SOPs, for the safety of training participants as well as the general public.

To protect the general public from intentional or accidental entry onto South Andersen property, locked or manned gates are used where vehicle access is provided and a series of warning signs (cautioning unauthorized personnel not to enter the area) are posted along the perimeter of the installation. Unauthorized personnel are not allowed on the installation at any time.

Guam International Raceway is situated on land proposed to be used to support LFTRC development. Periodic events at this raceway include drag racing and off-road vehicle competitions.

Environmental Health Effects

Noise

Andersen South open fields and wooded areas are used for basic ground maneuver training. Noise-generating activities associated with this training include vehicle use, use of breacher charges and pyrotechnics, and small arms firing. These operations are conducted at interior locations within the installation, away from the site boundary, and do not present a noise management issue. Details regarding current noise conditions at Andersen South are provided in Section 5.1.4.1.

The sporting events at the Guam International Raceway generate elevated vehicle noise.

Water Quality

Several water wells are situated within Andersen South or are immediately adjacent to the proposed Route 15 LFTRC boundary. These wells each have a mandated 1,000-foot (305-m) buffer identified as a wellhead protection zone. Within this zone, future activities and development are restricted to avoid contaminants from being introduced in them, and thus protecting the integrity of the island’s freshwater aquifers. Guam’s freshwater aquifers are susceptible to contamination from surface activities. GEPA requires treatment to ensure water quality meets safe drinking water standards. Section 5.1.2.1 provides details regarding current quality of potable water sources.

Hazardous Substances

Management practices and contingency plans for the use, handling, storage, transportation, and disposition of hazardous substances associated with Andersen South and the Guam International Raceway ensure their exposure to the environment and human contact is minimized.

The IRP focuses on cleaning up releases of hazardous substances that pose risks to the general public and/or the environment. The MMRP focuses on identifying and removing MEC. There are several IRP sites and AOCs located on Andersen South. However, because the development of the HG Range would
impact a relatively small area, only one AOC, AOC-64 (SWMU 42C Battery Shop), has the potential to be affected. This active site is associated with the Marbo Power Plant. The Hazardous Materials and Waste section of this SEIS (see Section 5.1.16) provides additional detail about the status of IRP/MMRP and AOC sites.

**Unexploded Ordnance**

The presence of UXO within the proposed Route 15 LFTRC area is unknown. However, Guam was an active battlefield during WWII. As a result of the occupation by Japanese forces and the assault by Allied/American forces to retake the island, unexploded military munitions may still remain.

**Traffic Incidents**

The nearest high crash frequency location in the vicinity of the proposed Alternative 1 is the intersection of Route 1 and Route 6 (approximately 1.5 miles [2.4 km] west of the entrance to Andersen South). It has been identified by the GPD as an intersection with a high rate of traffic incidents.

5.1.17.2 Environmental Consequences

**Operational Safety**

**Construction Safety**

Potential impacts on public health and safety from short-term construction activities would be similar to those discussed for the cantonment/family housing alternatives in Chapter 4. During construction activities, a health and safety program would be implemented by the construction contractors based on industry standards for accident prevention. Because a health and safety program would be implemented for construction activities and the general public would be excluded from entering construction areas, potential short-term construction impacts on public health and safety would not result in any greater safety risk. Therefore, no direct or indirect impact on public health and safety related to construction activities is anticipated.

**Operations/Range Safety**

To protect the general public from intentional or accidental entry onto live-fire training ranges, a series of warning signs cautioning unauthorized personnel not to enter the area would be posted along the perimeter of the installation as well as at the range area. Unauthorized personnel would not be allowed on the installation or range at any time. Civilian watercraft may inadvertently enter portions of the SDZ that extend over nearshore waters. Two Range Observation Towers would be erected to provide surveillance of the nearshore SDZ. Live-fire training would cease if the SDZ is penetrated by watercraft and would resume once the watercraft cleared the SDZ.

Activities within the LFTRC would include training to maintain military skills. The training would involve the firing of munitions; individual weapons training and combat skills; and crew, unit, and specialty combat skills.

The safety of the general public as well as personnel participating in military training events is a primary consideration for training activities. The fundamental guidance adhered to during training is that the range must be able to safely contain the hazard footprints of the weapons and equipment employed. The Range Safety Officer would ensure that hazardous areas are clear of personnel during training activities. After a live-fire event, the participating unit would ensure that weapons are safe and clear of live rounds.

Before training activities are conducted, SOPs require that the general public and non-participating personnel be cleared from the area. Therefore, the only public health and safety issue would be if a
training event exceeded the safety area boundaries. However, rules and procedures would be in place to eliminate the possibility of training events exceeding the safety area boundary. Direct risks to public health and safety would be reduced by confirming that the training area is clear.

Possible interactions between training activities within nearshore areas would be minimized by ensuring that the area is clear. Recreational diving activities within nearshore areas take place primarily at known diving sites, and dive boats typically are well-marked with diver down flags. The Marine Corps also may notify the general public of training activities through Notices to Airmen and Notices to Mariners.

Public notification of training activities, controlled use of established training areas, and compliance with appropriate range safety procedures would reduce the potential for interaction between the general public and personnel that are training. Specific and documented procedures would be in place so that the public would not be endangered by training activities. Therefore, Alternative 1 would result in no direct or indirect impact on public health and safety (resulting from operations and training activities).

**Explosive Safety**

For Alternative 1, SDZs have been defined for each of the ranges in the proposed LFTRC to identify the areas requiring control of unauthorized access to live-fire training operations. An SDZ defines the ground and airspace needed to laterally and vertically contain projectiles, fragments, debris, and components associated with the firing of surface-to-surface weapons. The DoD standard for risk acceptance on ranges is a 99.9999% level of containment, which means the probability of munitions (for inert ordnance) or a hazardous fragment (for live ordnance) escaping the SDZ is one in a million. SDZs established for Alternative 1 reflect a maximum potential adverse effect scenario for weapons use, to ensure the safety of on- and off-range personnel and civilians. The proposed layout of the SDZs is provided in Chapter 2. With implementation of appropriate range safety procedures, no impact on public health and safety is anticipated from Alternative 1 operations.

Ordnance used at Alternative 1 would be handled, stored, and transported in accordance with Marine Corps explosive safety directives (MCO P8020.10A, Marine Corps Ammunition Management and Explosives Safety Policy Manual), and munitions handling would be carried out by trained, qualified personnel. Therefore, no direct or indirect impacts related to explosive safety are anticipated.

**Environmental Health Effects**

**Noise**

Increases in noise emissions associated with implementation of the short-term construction phase of this alternative with identified BMPs would be less than significant. Enforcement of OSHA guidelines for hearing protection for workers would be the responsibility of the construction contractor. Alternative 1 activities would expose areas to noise levels considered incompatible with residential use. Noise from Alternative 1 activities (i.e., weapons firing) would be heard in areas adjacent to the range. Some adjacent lands north of Alternative 1 include residential uses and approximately 88 people could be exposed to incompatible noise levels (see Section 5.1.4.2). The sound generated from Alternative 1 activities would be intermittent (only when training activities occur) and short term.

Based on summaries of previous research (Thompson 1981; Thompson and Fidell 1989), predictions of non-auditory health effects of noise cannot be made. A valid predictive procedure requires: (1) evidence for causality between noise exposure and adverse non-auditory health consequences, and (2) knowledge of a quantitative relationship between amounts of noise exposure (dose) and specific health effects.
Because results of studies of noise on health are equivocal, a lack of sound scientific basis exists for making adequate risk assessments.

Alleged non-auditory health consequences of noise exposure that have been studied include birth defects, low birth weight, psychological illness, cancer, stroke, hypertension, sudden cardiac death, myocardial infarction, and cardiac arrhythmias. Of these, hypertension is the most biologically plausible effect of noise exposure. Noise appears to cause many of the same biochemical and physiological reactions, including temporary elevation of blood pressure, as do many other environmental stressors. These temporary increases in blood pressure are believed to lead to a gradual resetting of the body’s blood pressure control system. Over a period of years, permanent hypertension may develop (Peterson et al. 1984).

Studies that had controls for multiple factors have shown no, or a very weak, association between noise exposure and non-auditory health effects. This observation holds for studies of occupational and traffic noise as well as for aircraft noise exposure. In contrast to the early reports of two- to six-fold increases in hypertension caused by high industrial noise (Thompson and Fidell 1989), the more rigorously controlled studies of Talbott et al. (1985) and van Dijk et al. (1987), showed no association between hypertension and prolonged exposure to high levels of occupational noise. Two large prospective collaborative studies of heart disease are of particular interest. To date, cross-sectional data from these studies offer contradictory results. Data from one study showed a slight increase in mean systolic blood pressure in the noisiest compared to the quietest area, while data from the second study showed the lowest mean systolic blood pressure and highest high-density lipoprotein cholesterol (lipoprotein protective of heart disease) for men in the noisiest area (Babisch and Gallacher 1990).

Based on the modeled noise for proposed activities (see Section 5.1.4), the overall direct or indirect impacts associated with noise on public health and safety would be less than significant.

**Water Quality**

Potential impacts on public health and safety from water quality concerns would be similar to those discussed for the cantonment/family housing alternatives. Although groundwater withdrawal would likely increase, implementation of sustainability practices would reduce the amount of groundwater needed, which would help minimize impacts on groundwater availability. The resulting total annual groundwater withdrawal would be less than the sustainable yield, and monitoring of groundwater chemistry would identify any emerging issues to ensure no harm to the water supply (see Section 5.1.2.2). Water wells on and adjacent to Andersen South have a mandated 1,000-foot (305-m) buffer, identified as a wellhead protection zone. Proposed development and operational activities would be conducted to avoid these zones thereby eliminating the potential for contaminants to be introduced in these areas. Short-term construction activities and long-term operational activities associated with this alternative would be implemented in accordance with SOPs and BMPs, and in accordance with applicable regulations.

Because measures would be taken to maintain a sustainable water supply and water well locations would be protected from future development and operational activities, public health and safety impacts from long-term increased demand on potable water and potential water-related illnesses would be less than significant.

**Hazardous Substances**

Potential safety impacts from use of hazardous substances would be similar to those discussed for the cantonment/family housing alternatives. Implementation of this alternative would result in an increase in the use, handling, storage, transportation, and disposition of hazardous substances. These activities would
be conducted in accordance with applicable hazardous material and waste regulations, and established BMPs and SOPs to ensure that the health and safety of workers and the general public was maintained. IRP/MMRP and AOC investigations and/or remediation activities, as necessary, would continue in an effort to clean up past releases of hazardous substances that pose a risk to the general public and the environment and would receive regulator concurrence that necessary actions are completed to ensure the safety of the general public. Because hazardous substance management and IRP/MMRP investigative/cleanup activities would be conducted in accordance with applicable regulations and established BMPs and SOPs, no direct or indirect impact on public health and safety is anticipated.

With regard to exposure to airborne toxic dust related to live-fire training activities and range maintenance, lead is the primary contaminant of concern. Very small lead particles can become airborne if wind, foot traffic, or maintenance activities disturb lead-contaminated soil. Airborne particles smaller than 10 microns can be inhaled and fine particles smaller than 250 microns can be ingested incidentally. Intake of lead through inhalation usually is minor (Air Force 1998). Firing ranges would be designed and constructed so that participating personnel are not exposed to airborne contaminants above permissible limits. As a result, any emissions migrating off-range would likely be much lower. OSHA has established the permissible exposure limit for airborne lead as 50 µg/m$^3$ (Air Force 2011). Analysis of firing range emissions presented in the 2010 Final EIS (Volume 2, Chapter 5: Air Quality, Section 5.2.7: Summary of Impacts, Table 5.2-8: Summary of Training Impacts - Firing Range Alternatives page 5-36) indicated that operations emissions from firing range components would be well below significance criteria. Because range maintenance procedures ensure that participating personnel are not exposed to airborne contaminants above permissible limits and analysis of firing range emissions are below significance criteria, a less than significant direct or indirect impact on public health and safety from firing range activities is anticipated.

**Unexploded Ordnance**

Potential impacts from UXO would be similar to those discussed for the cantonment/family housing alternatives. Excavation for building foundations, roads, underground utilities, and other infrastructure could encounter unexploded military munitions in the form of UXO, DMM, and/or MPPEH. Exposure to MEC could result in death or injury to workers. With the exception of public access provisions outlined through the 2011 PA process (see Section 4.4.10, Cultural Resources), the general public would be excluded from entering construction zones and training areas. To reduce the potential hazards related to the exposure to MEC, ESS documentation would be prepared to outline specific measures that would be implemented to ensure the safety of workers and the general public. BMPs that would be implemented would include having qualified UXO personnel perform surveys to identify and remove potential MEC items before beginning ground-disturbing activities. Additional safety precautions would include having UXO personnel supervision during earth-moving activities and providing MEC awareness training to construction personnel involved in grading and excavations before and during ground-disturbing activities. In addition, the DON provides MEC awareness training to GovGuam and other public representatives allowing access to project sites to facilitate surveys or collection of natural resources or items of cultural significance prior to conducting vegetation clearance. Because UXO would be identified and removed before beginning construction activities and construction personnel would be trained about the hazards associated with unexploded military munitions, potential direct or indirect impacts from encounters with UXO would be minimized and would be less than significant.
Traffic Incidents

During scoping, concern was raised that because the Guam International Raceway would be removed to allow construction of the LFTRC, individuals would resort to local highways to conduct “drag racing” activities. This assumption is speculative. Such activities would be contrary to local traffic laws, and they would be highly dangerous not only to individuals participating in such illegal activity, but also to unsuspecting drivers on the road. However, because the venue for hosting legal racing events would be removed, it is possible that illegal forms of racing may increase in frequency on local roadways.

As part of Alternative 1 development, a portion of Route 15 would be realigned to the north, passing through what is now Andersen South. This realignment would interrupt the long, straight portion of Route 15, adjacent to Alternative 1. The elimination of the long, straight portion of Route 15 may reduce the appeal of this roadway for illegal street racing activities.

Overall potential long-term increase in the number of traffic accidents as a result of the increase in island population would be minimal; a less than significant direct or indirect impact on the public health and safety of the citizens of Guam (from traffic incidents) is anticipated.

5.1.18 Environmental Justice and the Protection of Children

5.1.18.1 Affected Environment

The affected environment under the Route 15 LFTRC alternative is considered to be the entire island of Guam, as discussed in Section 4.1.18.1 of this SEIS. The Route 15 LFTRC proposed action under this alternative would be located within the northern region of Guam, as defined in Section 4.1.18.1. The villages of Dededo and Yigo are within this region.

5.1.18.2 Environmental Consequences

Potential impacts to environmental justice populations from the Alternative 1 would be related to noise, recreation, land acquisition, and public health and safety. The impact analysis discussion provided in the following sections is focused primarily on operational impacts of implementing the proposed LFTRC alternative, as LFTRC construction impacts as related to environmental justice would be minimal and short-term, with no measurable effect on Guam’s special-status populations.

Noise

Noise generated during LFTRC construction with the potential to affect sensitive receptors would be due to grading and construction activities at the firing lines and at the range operations facilities located closest to the nearest receptors. Graders and scrapers would be approximately 67 dB at the nearest receptor. Construction would be direct but short-term and not exceed construction noise level standards and be considered less than significant.

The main source of noise associated with Alternative 1 would be small arms training at the proposed range complex. For those potential noise impacts from operation of the Route 15 firing ranges in which acceptable noise levels may be exceeded, the use of the potential mitigation measures would reduce noise levels to less than significant levels. Potential mitigation techniques available for reducing the noise impacts may include maintaining the current dense foliage and constructing berms to contain the sound. Maintaining the foliage or constructing the berms, or a combination of both, would reduce noise levels by 10-15 dB. A 10 dB reduction would be sufficient to reduce impacts to below significant levels.

Noise from the proposed HG Range would stay completely within the AAFB boundaries. Therefore, there would be no noise impacts to local residents.
Tier 1: Are there any minorities, low-income, or children populations that would be impacted?

Yes, noise-sensitive land uses within the north region of Guam include multi- and single-family residences, parks, churches, and schools. Racial and ethnic minority and low-income populations and children of the villages of Dededo and Yigo are presently adjacent to the proposed action site.

Tier 2: Are the applicable disadvantaged groups disproportionately affected by the negative environmental consequences of the proposed action(s)?

No, special-status populations would not be disproportionately affected by construction and operations related noise impacts from Alternative 1 because the entire region has minority, low-income, and children populations. All residents within the area of noise impacts for this alternative would be affected in the same manner. Therefore, minority and low-income populations would not be disproportionately affected by noise and there would not be disproportionate risks to the health and safety of children as a result of noise.

Recreation

As described in Section 5.1.7, Recreational Resources, there are numerous public recreational resources in northern Guam. Recreational resources that would potentially be affected by implementation of Alternative 1 include: Pågat and Marbo Caves (and the areas surrounding them), Guam International Raceway, and Taguan Trail. Other recreational opportunities in the north of Guam include trails, historic/cultural attractions, beaches/parks, scenic points, diving locations, and others (e.g., golf courses).

Alternative 1 avoids direct impacts to Pågat Village and Pågat Cave, and the potential indirect impacts from training noise on recreational resources is less than significant due to the generally alternating times of military training and peak recreational visitor use on weekends, when training usually does not occur. The use of the proposed LFTRC would result in restricted access to some dive spots, fishing zones and snorkeling areas used by the public. While Pågat Village, Pågat Cave, and Pågat Trail would not be impacted by implementation of this alternative, firing range SDZs would extend over the Pågat Point cultural site and would impact the public’s access to this archeological area during Marine Corps training.

In addition to temporary impacts to the access of other recreational resources in the construction area, the construction phase itself would require the closure of the Guam International Raceway. Based on scoping comments and public feedback, loss of the Raceway would have a long-term adverse effect to affect recreational resources in the community. Implementation of this alternative would require the closure of Guam International Raceway and the acquisition or leasing of that parcel, which would result in a significant direct impact to recreational resources. There would also be adverse indirect impacts from a sociocultural perspective due to the potential for the loss of the raceway park to deteriorate social networks. Because groups of people currently use the raceway park for social gatherings, if these gatherings at the raceway park ceased then the related social networks may lose cohesiveness.

Tier 1: Are there any minorities, low-income, or children populations that would be impacted?

Yes, recreational resources are generally used by all people of Guam, which includes a high proportion of racial or ethnic minorities, low-income individuals, and children.

Tier 2: Are the applicable disadvantaged groups disproportionately affected by the negative environmental consequences of the proposed action(s)?

No, minority and low-income populations and children would not be disproportionately affected by the increase in demand to recreation areas, because the entire region has a minority or special status
population. All people of Guam would be affected by impacts to recreational resources. Therefore, Alternative 1 would not result in disproportionately high and adverse effects on minority or low-income populations nor would there be disproportionate risks to the health and safety of children.

**Land Acquisition**

The following were identified as potential sociocultural issues of concern for individual landowners and occupants of land that would be acquired:

- **Land ownership and occupancy** - Although individuals are compensated for the economic value of acquired land (and related expenses), the loss of land is a long-term unplanned event that is disruptive to the owners and occupants of an acquired property who may value that property as an invaluable possession that cannot be replaced with money.

- **Social disarticulation and cultural marginalization** - Social disarticulation means that a person’s social capital or social resources are no longer available. Losing social capital or social resources amplifies the impacts of losing other (natural, physical, human) resources.

- **Social and psychological marginalization and stress and anxiety** - Social and psychological marginalization can be an impact of population displacement and relocation. Such impacts occur due to a person’s loss of confidence in society and themselves, feelings of injustice and reduced social status associated with economic marginalization (loss of economic power).

Further descriptions of these sociocultural issues and potential related impacts on Guam’s residents can be found in Section 5.2.2 of the SIAS (Appendix D).

No privately-owned land would be acquired under Alternative 1, so there would be no impacts to private land ownership. However, due to the extent of the proposed land acquisition and potential increase in federally owned or controlled land on Guam, and a reduction in access to lands of sociocultural and recreational importance, the overall socioeconomic impacts of land acquisition would be significant.

In general, direct and indirect economic impacts from the land acquisition are considered less than significant while indirect sociocultural impacts are considered long-term and significant. Land acquisition due to Alternative 1 may displace owner or non-owner occupants, reducing individual access to land-based resources, and potentially lead to social disarticulation. In addition, the Route 15 parcel includes four CLTC managed lots and one GALC managed lot. Because GALC ancestral lands are lands where qualified ancestral property rights can be accrued, and CLTC lands represent opportunities available for eligible Chamorro applicants, the acquisition of these lands eliminate these potential land uses, resulting in the possibility of cultural marginalization.

**Tier 1: Are there any minorities, low-income, or children populations that would be impacted?**

Yes, based on the data provided in Section 4.1.18-1, there are minority, low-income, and children populations in northern Guam.

**Tier 2: Are the applicable disadvantaged groups disproportionately affected by the negative environmental consequences of the proposed action(s)?**

No, because all of Guam is considered a racial and ethnic minority population, minorities would not experience disproportionately high and adverse effects due to land acquisition. Because federal regulations regarding land acquisition would ensure that significant economic impacts to landowners and occupants do not occur, low-income populations would not experience disproportionately high and adverse effects due to land acquisition. Land acquisition would not result in health and safety risks that
would disproportionately impact children. Therefore, Alternative 1 would not result in disproportionate land use or socioeconomic impacts to minority and low-income populations or children as a result of land acquisition.

Public Health and Safety

No impacts to public safety are anticipated from operational safety concerns (i.e., explosive safety, electromagnetic safety, construction safety). No impacts to public health and safety are anticipated from management of hazardous substances, and an additional demand to public health services (e.g., hospitals, outpatient clinics) is not anticipated. Less than significant impacts to public safety, from firing range air emissions, are anticipated. Less than significant impacts are anticipated from noise, water quality, and UXO.

*Tier 1: Are there any minorities, low-income, or children populations that would be impacted?*

Yes, the populations of the villages affected by Alternative 1 have high percentages of racial minorities, low income groups, and children.

*Tier 2: Are the applicable disadvantaged groups disproportionately affected by the negative environmental consequences of the proposed action(s)?*

No, impacts would not be disproportionate because regardless of where the LFTRC is located on Guam, high (relative to the U.S.) percentages of minorities, low-income residents, and children would be affected. As LFTRC alternatives may only occur on Guam (by international treaty), and all of Guam is considered to have a high proportion of minorities, low-income residents, and children, impacts cannot be considered disproportionate.
5.2 **NAVAL MAGAZINE (EAST/WEST) LIVE-FIRE TRAINING RANGE COMPLEX - ALTERNATIVE 2**

Under Alternative 2, the proposed development of a live-fire training range complex would occur at NAVMAG East/West. Details about this alternative are provided in Section 2.5.4.2 and the proposed site is illustrated in Figure 2.5-3.

5.2.1 **Geological and Soil Resources**

5.2.1.1 Affected Environment

The affected environment for the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.1.1 of this SEIS.

The affected environment for geological and soil resources associated with Alternative 2 is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 3: Geological and Soil Resources, Section 3.1.5 South, pages 3-26 to 3-28), which is summarized below for reference. The proposed reduction in the number of relocating Marines and dependents under the 2012 Roadmap Adjustments does not alter the description of the affected environment for geological and soil resources, but it would reduce some potential impacts to geological and soil resources that were determined to be less than significant or mitigated to less than significant in the 2010 Final EIS, as described in the analysis of environmental consequences for Alternative 2 below.

Alternative 2 would be located in a topographically rugged, hilly-to-mountainous area in the south-central part of Guam. Within the proposed project footprint, elevations range from approximately 200 feet (61 m) above MSL along the northeastern extent to approximately 520 feet (158 m) MSL along the southern extent of the footprint. To the northwest of the proposed Alternative 2 footprint is Fena Valley Reservoir, and to the west is Mount Almagosa.

The proposed Alternative 2 footprint is underlain by volcanic bedrock. One known minor bedrock fault crosses the footprint and there are multiple others (including one major) in the surrounding area (Figure 5.2.1-1). The soils of Guam are described in the 2010 Final EIS (Volume 2, Chapter 3: Geological and Soil Resources, Section 3.1.1.3 Geologic Units, Figure 3.1-4 and Table 3.1-1, pages 3-8 to 3-9). Three soil groups cover the majority of the footprint: Ylig clay, Togcha-Akina silty clay, and Akina Badland Association (Figure 5.2.1-2). Depth and drainage capacity of these soil groups vary from very shallow to very deep, and well drained to poorly drained (Young 1988). The Agfayan Clay, Akina-Atate-Silty Clay, and Akina Silty Clay cover the remainder of the footprint. For the latter three groups as a whole, runoff is medium to rapid, and the water erosion hazard is moderate to severe (Young 1988).

The three dominant soil types in the proposed Alternative 2 footprint are considered limited agriculturally-productive soils because of the elevated acidity of these soils. However, these soils support production of watermelons and pineapples (Young 1988). Prime farmland soils, as defined by the USDA, are soils best suited to producing food, seed, forage, fiber and oilseed crops, favorable for economic production and sustained high yield, with minimal inputs of energy and resulting in least damage to the environment (Young 1988). The Togcha component of the Togcha-Akina silty clay group meets the requirements for prime farmland when irrigated (Young 1988).

Figure 5.2.1-2
Soils in the Vicinity of NAVMAG (East/West) LFTRC Alternative 2

Sources: NAVFAC Pacific 2013; NRCS 2006
With respect to geologic hazards (see Section 3.1.1.1) there is one major bedrock fault mapped within the Alternative 2 footprint. The overall likelihood for landslides to occur is considered high due to many areas combining steep slopes with soils vulnerable to slipping in seismic events (see Figure 5.2.1-1). The maximum reported tsunami waves height reached on Guam was approximately 11.5 feet (3.5 m) in an 1849 tsunami event. The area proposed for development of Alternative 2 is located away from the coastline and above the elevation susceptible to tsunamis. The Alternative 2 footprint is not subject to liquefaction because it is underlain by consolidated volcanic bedrock (see Figure 5.2.1-1). There are no preliminary identified topographic features that may contain sinkholes in the volcanic bedrock underlying the Alternative 2 footprint.

5.2.1.2 Environmental Consequences

Construction

Construction impacts associated with the HG Range at Andersen South would be similar to those described under Alternative 1 in Section 5.1.1.2 of this SEIS.

Construction of the new ranges, range support building, roads, bridges, and related infrastructure associated with Alternative 2 would include clearing, grubbing and grading, and excavation (cut) and filling, and stream rerouting. Earthwork would include 1,246,720 yd³ (953,186 m³) of cut (excavation) and 1,254,698 yd³ (959,286 m³) of fill, with a net of 7,981 yd³ (6,102 m³) of fill. Alternative 2 would involve the least volume of excavation of any of the action alternatives. Within the Alternative 2 footprint, there are 30-feet (10-m) differences in elevation in the areas planned for construction of the MPMG and MRF ranges. There would be substantial changes to surface elevation for construction of the MPMG and MRF ranges. However, at the other four LFTRC alternatives, the locations proposed for the MPMG Range have greater elevation differences than at Alternative 2. For example, at Alternative 2, 30-feet (10-m) high slopes would be leveled with about 942,500 yd³ (725,000 m³) of cut and 910,000 yd³ (700,000 m³) of fill. To build the MPMG Range at Alternative 1, 60-foot and 30-foot high (20- and 30- m) slopes would be leveled over the 1,000 m (0.5 mile) length of the range. Nearly the same amount of fill and 2.5 times as much cut would be needed. Because the elevation changes at Alternative 2 are smaller than those of the other alternatives, less excavation, filling and contouring would occur at Alternative 2 so there would be less alteration of the surrounding landscape than at the other four alternatives. Therefore, construction of Alternative 2 is expected to have a less than significant direct, long-term impact on topography. Because the impact to topography would be less than significant, no mitigation measures are proposed.

Construction of the HG Range would involve 8,894 yd³ (6,800 m³) of cut and 12,641 yd³ (9,665 m³) of fill, for a net of 3,747 yd³ (2,865 m³) of fill. Thus, the total net fill for Alternative 2 would be 11,728 yd³ (8,967 m³).

There is a potential for increased erosion, compaction, and soil loss from physical disturbance caused by construction activity and changes to existing topography. However, project design and construction would incorporate engineering controls as BMPs to minimize erosion within the project construction footprint, as required by 22 GAR Chapter 10 Guam Soil Erosion and Sediment Control Regulations. Examples of such engineering controls include:

- Use of drainage diversion and control to temporarily direct runoff from adjacent undisturbed areas away from construction sites.
- Use of benches or terraces and drainage control on cut or fill slopes higher than 15 feet (5 m) to minimize erosion on slope faces.
• For each project, limit the size of the unstabilized disturbed areas to less than 20 acres (8 ha) during construction.

• Planning earth-moving operations for periods of low rainfall to minimize exposure of disturbed soil to potential runoff.

• Re-vegetating and permanently stabilizing disturbed areas as soon as possible.

• Engineering project slopes in consideration of soil and geological conditions to avoid and minimize erosion.

• Compliance with the DoD Program-level SWPPP for construction, in addition to individual project SWPPPs during construction to reduce the potential for erosion, runoff, sedimentation, and stormwater pollutant loading.

In addition, construction activities associated with Alternative 2 would comply with the Construction General Permit. Potential construction-specific stormwater BMPs would be implemented in compliance with the Construction General Permit as listed in Section 4.1.2-2. Construction-specific stormwater BMPs would provide erosion and sediment control during the construction period, generally by employing on-site measures that reduce the flow of stormwater and minimize the transport of soils and sediment off-site. Fill material would be generated on-site, whenever possible. Roadway-specific BMPs, as identified in the most recent CNMI and Guam Stormwater Management Manual, would be included in the planning, design, and construction of all roadways and facilities. Through compliance with 22 GAR Chapter 10 and the Construction General Permit and implementation of roadway stormwater BMPs, and because the rate of erosion and soil loss would not be substantially increased, direct, short-term impacts to soils from erosion during construction of Alternative 2 would be less than significant. In addition, no indirect, short-term impacts associated with soil erosion are expected.

Construction of Alternative 2 would disturb agriculturally productive soils that are identified by the USDA as prime farmlands. As described in Section 5.2.6 of this SEIS (Land and Submerged Land Use), no existing agricultural use is identified for the area of disturbance. Therefore, disturbance of these soils would be an adverse, but less than significant direct long-term impact.

There are no sinkholes within the proposed Alternative 2 footprint, so no direct or indirect impacts to sinkholes would occur with construction of Alternative 2.

Hazards associated with earthquakes, fault rupture and slope instability would be minimized by adherence to UFC 3-310-04 Seismic Design of Buildings dated June 1, 2013 (USACE 2013). The NAVMAG (East/West) LFTRC alternative is sited above the elevation prone to tsunamis, and so would not be susceptible to inundation. The volcanic bedrock underlying the site is not vulnerable to liquefaction. In addition, there would not be a change to soil and/or bedrock conditions that would increase vulnerability to a geologic hazard. Therefore, construction of Alternative 2 would result in less than significant direct and indirect short-term impacts with respect to geologic hazards.

Operation

Operational impacts associated with the HG Range at Andersen South would be similar to those described under Alternative 1 in Section 5.1.1.2 of this SEIS.

Operations at the proposed Alternative 2 would not alter topography post construction, so no direct or indirect long-term impacts to topography would occur.

Operational activities and conditions that may directly cause or increase naturally occurring soil erosion at a firing range would include ongoing soil disturbances resulting from vehicular and pedestrian traffic and
inadequate maintenance of vegetated areas. The changes to topography caused by construction of the MPMG and MRF ranges raise the risk of erosion during the operational phase, because graded features (cut and fill slopes), shifted stream channels, and altered surface flow patterns can potentially create conditions that may facilitate additional soil erosion (NAVFAC Pacific 2013a).

The area of impervious surfaces that would be constructed for the ranges and associated infrastructure (range buildings, roads, and parking areas) totals approximately 29.9 acres (12.1 ha) including about 29.0 acres (11.7 ha) for Alternative 2 and about 0.9 acre (0.4 ha) for the HG Range (Appendix F). There would be a minor increase in runoff from the new impervious surface areas as compared with existing conditions. Stormwater infrastructure improvements included as part of the proposed action would incorporate LID measures and BMPs to minimize soil erosion from this increased runoff. Where possible, stormwater flow paths would continue to mimic pre-development flows through area topography. Stormwater BMPs that would be implemented to minimize and control runoff would also minimize soil erosion.

The LFTRC would be managed in accordance with current Marine Corps range management policies and procedures, which are designed to ensure the safe, efficient, effective, and environmentally sustainable use of the range area. A thorough explanation of Marine Corps range management is detailed in the 2010 Final EIS (Volume 2, Chapter 2: Description of Proposed Action and Alternatives, Section 2.3.1.4: Firing General Military Skills, pages 2-55 to 2-59). Marine Corps range management policies and procedures include procedures for removing expended rounds from live-fire ranges with impact berms every 5 years, managing stormwater, controlling erosion, maintaining vegetation on berms and drainage ways and turf on the range, and restricting vehicular activities to designated/previously identified areas. Range roads would be maintained to minimize erosion.

There would be minor ground disturbance associated with utility maintenance. Construction stormwater BMPs would be implemented during maintenance activities to minimize and control runoff on-site and minimize potential effects of erosion.

Prime farmland soils would be disturbed. As described in Section 5.2.1.1 of this SEIS, no existing agricultural use is identified for the area of disturbance. Therefore, disturbance of these soils during the Alternative 2 operational phase would be an adverse, but less than significant, direct long-term impact.

A potential indirect impact of firing range operations includes the possibility of live ammunition causing wildland fires. As a BMP and in accordance with range safety protocols, a Range Fire Management Plan would be prepared, based on the DON’s existing Wildland Fire Management Plan (USFS 2008). It would include protocols for monitoring fire conditions and adjusting training as needed. Units undergoing training at the ranges would be briefed by range control on requirements suitable to the conditions of the day and protocols should a fire occur (e.g., specifying how the range would shut down and how fire suppression action would be taken). The existing Wildland Fire Management Plan (USFS 2008) that covers NAVMAG would be extended to cover bordering non-federal lands that could spread fire onto the ranges and would continue to be implemented under Alternative 2. With these measures, potential wildfires caused by the live ammunition would be unlikely. Effects to soils from erosion associated with wildfires associated with operation of Alternative 2 would be minimal and direct and indirect short- and long-term impacts would be less than significant.

With implementation of Marine Corps range management policies and procedures, fire suppression and potential mitigation measures, and stormwater BMPs (for ranges and utility maintenance), and because the rate of erosion and soil loss would not be substantially increased, less than significant direct and indirect long-term impacts to soils from erosion would occur due to Alternative 2 operations.
There are no sinkholes in the volcanic bedrock of the proposed Alternative 2 footprint, so Alternative 2 operations would have no direct or indirect long-term impacts to sinkholes.

Hazards associated with earthquakes, fault rupture and slope instability would be minimized by adherence to UFC 3-310-04 Seismic Design for Building dated June 1, 2013 (USACE 2013) during project design and construction, so direct and indirect long-term impacts with respect to seismic hazards would be less than significant. The consolidated volcanic bedrock underlying the site is not vulnerable to liquefaction. Alternative 2 is inland and higher than the elevation prone to tsunamis, so it would not be susceptible to inundation. In addition, there would not be a change to soil and/or bedrock conditions that would increase vulnerability to a geologic hazard. Therefore, operation of Alternative 2 would have less than significant direct and indirect long-term impacts associated with geologic hazards.

5.2.2 Water Resources

5.2.2.1 Affected Environment

The affected environment for water resources in the Alternative 2 NAVMAG ranges is described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.1.5.1: Naval Munitions Site, pages 4-68 to 4-71). A summary of site conditions for Alternative 2 is provided in Appendix F. The affected environment for the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.2.1 of this SEIS.

Surface Water

As indicated in the 2010 Final EIS, numerous rivers and a portion of Fena Reservoir are located within the NAVMAG portion of the project area. Numerous rivers are also located in the non-DoD portion of the project area. Specifically, the proposed construction areas and SDZ for the Alternative 2 ranges are spatially located along the Sagge, Sarasa, and Malaja river systems of the southern Talofofo Watershed; the Almagosa, Sadog Gago, and Imong river systems of the Central Talofofo Watershed (note: referred to as the “Fena Reservoir Watershed” in the above referenced section of the 2010 Final EIS); and the Bubulao River of the Ugum Watershed (Figures 5.2.2-1 and 5.2.2-2) (NAVFAC Pacific 2013a). The Fena Valley Reservoir is located within the Central Talofofo Watershed.

The watersheds in the Alternative 2 project area are extensively covered by savanna grasslands that can be considered to be highly susceptible to wildland fire. Wildland fires in the savanna grasslands often completely consume the above ground plant cover, leaving the soils exposed to rain and accelerated erosion. Soil erosion can degrade water quality in rivers and Fena Valley Reservoir and over time can diminish the storage capacity of Fena Valley Reservoir. Decades of periodic burning of the savanna plant communities have resulted in severe soil erosion and leaching of essential nutrients. Off-road activity appears to be extensive on non-federal lands, which may further aggravate soil erosion. Overall, the Alternative 2 project area is located on various types of Akina soils, which are characterized by relatively high soil erosion potential and can produce high concentrations of very fine clay suspended sediments (NAVFAC Pacific 2013a).

Surface Waters and Wetlands in the Vicinity of NAVMAG (East/West) LFTRC Alternative 2

Sources: WERI 2001; USGS 2003; FEMA 2007; USFWS 2010; NAVFAC Pacific 2013
Ugum Watershed is included in GEPA’s impaired waterbodies 303(d) list for elevated turbidity and USEPA Region 9 approved a TMDL for sediment in the Ugum Watershed in February 2007. The primary pollutant source identified in the TMDL was the nonpoint source from soil erosion. Because the soils of the Ugum Watershed have a very high clay content (40%), much of the eroded soil ends up in the Ugum River and is carried to Talofofo Bay (GEPA 2006). This contributes to poor quality in-stream aquatic habitats, smothering of the coral reefs, and a decline in fish populations (GEPA 2006). The TMDL analysis indicated that sediment loads to waterways in Ugum Watershed would need to be reduced by approximately 25% to attain the TMDL and remedy the impacts of excessive sedimentation on the river. For the Bubulao Watershed (a sub-watershed within the Ugum Watershed) in the project area, annual and daily load allocations to meet the TMDL are 14,000 tons/year (12,700 metric tons/year) and 38 tons/day (34 metric tons/day), respectively (GEPA 2006).

The Federal Emergency Management Agency (FEMA)-mapped 100- and 500-year floodplains are also shown in Figure 5.2.2-2.

**Groundwater**

As indicated in the 2010 Final EIS, groundwater is found primarily in the low-permeability volcanic rocks and there is currently no groundwater extraction in the Alternative 2 project area.

**Nearshore Waters**

As indicated in the 2010 Final EIS, there are no nearshore waters located near the Alternative 2 project area due to its interior location on Guam. However, the Ugum River joins the Talofofo River and discharges into Talofofo Bay (see Figure 5.2.2-1). As noted under Surface Water, sediment in runoff from these rivers contributes to smothering of the coral reefs and a decline in fish populations (GEPA 2006).

**Wetlands**

As indicated in the 2010 Final EIS, there are extensive wetlands within the NAVMAG portion of the Alternative 2 project area. Recent on-site wetland confirmation surveys were conducted at NAVMAG in May and November 2012 and at the non-federal lands in May and June 2012 for this SEIS. The on-site confirmation was a non-jurisdictional wetland delineation (delineation being the establishment of wetland boundaries). A jurisdictional delineation establishes the boundaries of wetlands that are subject to requirements in the CWA and its implementing regulations and requires the approval of the USACE.

The wetlands identified during the 2012 survey are palustrine emergent wetlands with persistent vegetation that are either seasonally flooded/saturated (PEM1E) or semi-permanently flooded (PEM1F). The 2012 field survey delineated a total of 17.7 acres (7.2 ha) of wetlands in the project area as shown in Table 5.2.2-1 and Figure 5.2.2-2 (NAVFAC Pacific 2013b). These wetlands are all considered potentially jurisdictional pending a jurisdictional determination by the USACE.

For portions of the project area located outside the 2012 field survey, National Wetlands Inventory (NWI) data were used (NWI maps indicate the potential for wetland areas, but are not official determinations). The NWI maps indicate 3.6 acres (1.4 ha) of NWI wetland areas as shown in Table 5.2.2-1 and Figure 5.2.2-2 (USFWS 2010). The NWI wetlands are identified as palustrine emergent that are semi-permanently flooded (PEM1F) and palustrine forested that are seasonally flooded (PFO3C). The project area outside the 2012 survey area would require a wetland delineation survey and review by the USACE to verify the location and size of any wetlands and whether they are jurisdictional.

5.2.2.2 Environmental Consequences

**Construction**

General construction impacts to water resources would be similar to those described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.4: South, page 4-112) and under Alternative A in Section 4.1.2.2 of this SEIS. Alternative 2 would occur in an area that contains waters of the U.S. and would be required to comply with the Construction General Permit as described under Alternative A in Section 4.1.2.2 of this SEIS. Construction impacts associated with the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.2.2 of this SEIS.

Under Alternative 2, proposed LFTRC construction activities at NAVMAG and non-federal lands would result in the potential for a short-term increase in stormwater runoff, erosion, and sedimentation. However, through compliance with the Construction General Permit Program SWPPP and implementation of a site-specific SWPPP and associated erosion control, runoff reduction, and sediment removal BMPs (see Table 4.1.2-2), these effects would be minimized. Specifically, the site-specific SWPPP would identify appropriate BMPs for the site that would serve to contain runoff and sediment on-site by reducing the flowrate of runoff and thereby minimize transport of suspended sediment through settling and promote infiltration of runoff.

**Surface Water**

Surface waters that are potentially affected by the various project footprints are shown in Figure 5.2.2-2. The MRF Range would drain to the Sagge River and one of its major unnamed tributaries. This unnamed tributary, located south of the Sagge River, would also receive flows from the area proposed for locating the KD Rifle Range. The rest of the area where the proposed KD Rifle Range would be sited would drain through a wetland area to the Sarasa River. The MPMG and the KD Pistol ranges would drain to the Malaja River with small portions of the MPMG Range draining to the Sarasa and Bubulao rivers. The Non-standard Small Arms Range would be located entirely within an area draining to the Bubulao River (NAVFAC Pacific 2013a). The access road would cross the Bubulao and Ugum rivers (see Figure 5.2.2-1). The range roads would cross the Sarasa, Malaja, and Bubulao rivers.

The Watershed Reconnaissance Study for the Potential Site of the Live Fire Training Ranges Complex, Guam (hereafter referred to as the Watershed Reconnaissance Study) was conducted by NAVFAC Pacific (2013a) to assess potential impacts to surface waters in the Alternative 2 project area and identify BMPs to minimize adverse effects due to construction (see Appendix F). Construction under Alternative 2 would include clearing of vegetation, grading (cut and fill), permanent or temporary accumulation of soils, stream rerouting, and filling in of natural areas. The MRF Range and MPMG Range construction would require substantial amounts of grading.
Potential effects from stormwater runoff would be minimized by adhering to the provisions of the Construction General Permit and implementing a Program SWPPP and site-specific SWPPP and associated BMPs that would address site- and activity-specific surface water protection requirements. Implementation of construction BMPs under Alternative 2 would also support compliance with load allocations under the sediment TMDL for Ugum Watershed. There would be no construction in the watershed contributing to Fena Valley Reservoir, and therefore no construction-related impacts would occur to the water quality of Fena Valley Reservoir.

Construction activities that involve substantial earth moving would be scheduled for the dry season (January to May), to the extent possible. While rain falls in Guam during the dry season, the rains are usually not as frequent or intense, and the sediment-laden flows from construction areas would therefore be relatively easily managed (NAVFAC Pacific 2013a). Working in and around streams with flowing water would require special consideration because the eroded and/or disturbed sediments would not have to travel too far to enter the regional drainage system. In many of the smaller streams, the dry season characteristically has lower flows or possibly none at all, and therefore work around stream channels would be prioritized for the peak of the dry season. As necessary, flows may have to be re-directed or pumped around the worksite, but this would be temporary and not substantially alter flows. Any permanent relocation of channels or construction of bridges or culverts would also be completed before the start of the rainy season. All bridges and culverts would be designed and constructed so as not to negatively impact the hydrology of surface waters and wetlands. Altered stream banks would be finished, protected, and re-vegetated before the start of the rainy season. Relocating and/or rerouting of natural drainage channels would be subject to USACE Section 404 and GEPA Section 401 permit requirements.

Given the short-term nature of potential surface water impacts, compliance with Construction General Permit requirements, and implementation of BMPs, construction activities associated with Alternative 2 would result in less than significant direct or indirect short-term impacts to surface water.

**Groundwater**

Construction activities under Alternative 2 would include stormwater runoff protection measures that would also serve to protect groundwater quality. By adhering to the provisions of the Construction General Permit and implementing BMPs associated with addressing site- and activity-specific water resource protection requirements, there would be a reduction in stormwater pollutant loading potential and thus a reduction in pollution loading potential to the underlying groundwater basins. Given stormwater runoff protection measures (i.e., compliance with Construction General Permit requirements and implementation of BMPs), construction activities associated with Alternative 2 would result in less than significant direct short-term impacts to groundwater.

**Nearshore Waters**

Construction activities associated with Alternative 2 would occur more than 1 mile (1.6 km) from the coastline and would not result in direct impacts to the nearshore waters from stormwater runoff. Compliance with the Construction General Permit and implementation of BMPs under Alternative 2 would support the compliance with load allocations under the sediment TMDL for Ugum Watershed and ensure that stormwater runoff from the project area would not cause indirect impacts to nearshore waters in Talofofo Bay (see Figure 5.2.2-1). Given stormwater runoff protection measures (i.e., compliance with Construction General Permit requirements and implementation of BMPs), construction activities associated with Alternative 2 would result in no direct or indirect short-term impacts to nearshore waters.
Wetlands

Implementation of Alternative 2 could result in direct long-term impacts to up to 17.7 acres (7.2 ha) of potentially jurisdictional wetland areas (see Figure 5.2.2-2). These direct impacts would be at the MPMG Range from cut and fill of wetlands associated the Sarasa River and Malaja River. There are an additional 3.6 acres (1.4 ha) of NWI wetlands in portions of the project area that have not been surveyed (see Section 5.2.2.1 in this SEIS).

Direct impacts (fill) to jurisdictional wetlands would be a significant impact. If these wetland areas are determined to be jurisdictional by the USACE, and therefore subject to Section 404 requirements, the Marine Corps would first attempt to avoid impacts. If avoidance is not possible, then the Marine Corps would obtain a Section 404 permit from the USACE to fill the wetlands and comply with minimization and potential mitigation measures outlined in the permit (see Table 5.7-1). Unavoidable direct impacts to jurisdictional wetlands would be mitigated by creating new wetlands, restoring or enhancing existing wetlands, or preserving existing wetland areas on Guam to, at a minimum, replace the area filled at a mitigation ratio greater than 1:1.

As required under the Section 404 permitting process, a mitigation plan would be prepared that would identify sites for compensatory mitigation and include a description of the type(s) and amount(s) of compensation, the method of compensation (i.e., restoration, establishment, enhancement, and/or preservation), and how the resource functions of the compensatory mitigation would address the needs of the watershed, ecoregion, or other geographic area of interest (GBSP 2009). Compensatory mitigation would follow guidelines provided in the Guam Compensatory Mitigation Policy (GBSP 2009). The Guam Compensatory Mitigation Policy identifies wetland restoration as the preferred compensatory mitigation option and states that “compensatory mitigation should be located within the same watershed as the impact site and should be located where it is most likely to successfully replace lost functions and services, taking into account such watershed-scale features as habitat diversity, habitat connectivity, relationships to hydrologic sources (including the availability of water rights), trends in land use, ecological benefits, and compatibility with adjacent land uses.” There are limited opportunities on Guam to restore freshwater wetlands within the same watershed as the impacted site. The Marine Corps has identified the Camp Covington wetlands and portions of the Atantano River wetlands in nearby watersheds as potential Moorhen habitat wetland restoration sites at the Waterfront Annex at Apra Harbor, Naval Base Guam (NAVFAC Pacific 2013c). The suitability of these sites as compensatory mitigation for wetland impacts would be determined during the Section 404 permitting process. Additional sites may also be identified to meet wetland compensatory mitigation requirements.

If Alternative 2 is chosen and wetlands cannot be avoided, the Marine Corps understands that a LEDPA determination must be made as part of the permitting process and that if the USACE determines this alternative is not the LEDPA, a Section 404 permit under the CWA cannot be granted and Alternative 2 would not be implemented. Through implementation of the potential mitigation measures and procedures identified above, significant impacts to wetlands would be reduced to a level below significant. By comparison, Alternatives 1 and 5 would have no impacts to wetlands and Alternatives 3 and 4 would have significant long-term, direct impacts to up to 36.9 acres (15.0 ha) and 25.2 acres (10.2 ha) of potentially jurisdictional wetland areas, respectively, which would be mitigated to a level below significant.

There would also be potentially jurisdictional wetlands adjacent to and downstream of construction areas that would be subject to potential indirect impacts during construction. These short-term, indirect impacts would be minimized by adhering to the provisions of the Construction General Permit and implementing BMPs associated with addressing site- and activity-specific stormwater runoff protection requirements.
Operation

Alternative 2 would incorporate the concept of LID in the final planning, design, and permitting of the stormwater runoff and drainage design as described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.1: North, pages 4-85 to 4-87) and under Alternative A in Section 4.1.2.2 of this SEIS. Operation impacts associated with the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.2.2 of this SEIS.

Under Alternative 2, there would be a minor increase in the area of impervious surface as a result of ranges and associated support facilities, which would result in an associated increase in stormwater discharge intensities and volume. However, the proposed action would incorporate LID measures and BMPs to ensure stormwater retention would be consistent with local and federal requirements and thus minimize potential impacts to surface water quality. Alternative 2 would also be implemented in accordance with all applicable orders, laws, and regulations including the preparation and implementation of a SWPPP, SWMP, and SPCC plan that would control runoff and minimize potential leaks and spills. Where possible, stormwater flow paths would continue to mimic pre-development flows through area topography.

Alternative 2 would include implementation of the REVA program and range management preventative measures (i.e., vegetation, pH adjustment, LID). As listed in Section 2.8 of this SEIS, the BMPs would reduce the potential for contaminants to migrate off-site. In addition, the DoD would investigate additional technologies that could assist with range design and management to minimize potential impacts. Available baseline data regarding range site conditions would be reviewed and verified prior to range construction and quarterly monitoring would occur during operations to verify the effectiveness of BMPs. For each range, water quality treatment strategies would be selected to achieve reductions of non-point source pollutants to meet the same water quality requirements as identified under Alternative A in Section 4.1.2.2 of this SEIS.

Surface Water

The Watershed Reconnaissance Study (NAVFAC Pacific 2013a) identified potential impacts to surface waters during the operational phase of Alternative 2 (see Appendix F). Activities that may directly cause or exacerbate naturally occurring soil erosion and sediment runoff from a firing range would include ongoing soil disturbances resulting from vehicular and pedestrian traffic; inadequate maintenance of vegetated areas; increased stormwater runoff volume and velocity; contamination of stormwater runoff due to eroded sediments, lead, and other MCs; and discharge of untreated contaminated stormwater runoff into surface waters and wetlands. An indirect impact of firing range operations would result from the use of live ammunition causing wildland fires. Large amounts of earthwork at the MRF and MPMG ranges raise the risk of erosion during the operational phase, because graded features (cut and fill slopes), shifted stream channels, and altered flow patterns can potentially create conditions which may facilitate additional soil erosion (NAVFAC Pacific 2013a).

Potential effects from stormwater runoff would be minimized through the implementation of an appropriate and comprehensive stormwater management plan utilizing a LID approach and BMPs under Alternative 2 that would also serve to support the compliance with load allocations under the sediment TMDL for Ugum Watershed. The runoff from operational areas is also the primary mechanism for off-site transport of eroded sediments and potentially harmful MCs, including lead. Firing range operational-phase LID measures and BMPs would focus on reducing volume and velocity of stormwater runoff, minimizing soil erosion potential within the range boundaries, and controlling the spread of lead bullets and bullet fragments. Lead mobilization in stormwater runoff would be of greater concern within the...
actual range footprint than within the dispersion area, which may only receive stray bullets (NAVFAC Pacific 2013a). The most effective BMP for managing lead at a firing range is by containing and limiting the spread of the spent munitions. This would be achieved through the use of containment systems, which trap and hold the spent munitions until they can be recovered for off-site disposal (NAVFAC Pacific 2013a). Commonly used spent-munitions containment systems include earthen berms and backstops, sand traps, steel traps, lamella or rubber granule traps, and shock-absorbing concrete. Each type of system would be customized during final design for use at a given range to enhance its effectiveness. The REVA program and additional BMPs listed in Section 2.8 of this SEIS would be implemented to minimize off-site migration of lead contaminants. In addition, the low volume use of explosives during training activities could result in a potential for a very small amount of remaining, non-consumed material to remain in the remaining explosive case. However, these residual compounds would not present a significant threat to water quality due to their relatively low volume of use and the large area in which they would be used.

Appropriate fire suppression and potential mitigation measures would also be incorporated into the design (fire resistant structures) and range operating procedures. These measures would include landscaping with fire-resistant vegetation that can become established in the depleted soils. Overall, Alternative 2 appears to have the highest fire susceptibility compared to the other two NAVMAG alternatives. The likelihood of outside fire sweeping onto the proposed ranges would also be high and would pose an elevated risk to range property and operations. The existing Wildland Fire Management Plan (USFS 2008) that covers NAVMAG would be extended to cover the non-federal lands and would continue to be implemented under Alternative 2.

Because none of the proposed Alternative 2 firing range footprints fall within the Central Talofofo Watershed, stormwater runoff from the proposed range footprint areas would not drain to the Fena Valley Reservoir (see Figure 5.2.2-2). However, the SDZ associated with Alternative 2 would partially overlay the Central Talofofo Watershed (see Figure 5.2.2-2), but there would be a very small chance that an expended projectile would fall in the SDZ outside of the range footprint. Given the small number of potential projectiles that could fall into the watershed and the relatively small size of the projectiles, potential impacts to the water quality of Fena Valley Reservoir from these projectiles would be negligible.

No buildings/structures would be constructed in the 100-year or 500-year flood zone. It is anticipated that developing the proposed footprint areas would not impact water surface elevation levels in FEMA-regulated floodplains. However, this would be confirmed through detailed hydraulic and hydrologic modeling during the final design phase. Any rise in the elevations would be covered by FEMA regulations and would need to be approved by the local floodplain administrator.

Alternative 2 operations would be conducted in accordance with all applicable orders, laws, and regulations including the preparation and implementation of a SWPPP, SWMP, and SPCC Plans that would control runoff and minimize potential leaks and spills. Given implementation of these stormwater runoff protective measures and range operation BMPs for containing and limiting the migration of lead contaminants, operations associated with Alternative 2 would result in less than significant direct or indirect long-term impacts to surface water.

**Groundwater**

Under Alternative 2, proposed operations would be in compliance with the stormwater runoff protection measures identified above that would also serve to protect groundwater quality and recharge. Specifically, implementation of LID measures and the provisions of the SWPPP and associated erosion control activities would ensure that any stormwater runoff recharging to groundwater basins would be of
acceptable quality. BMPs to minimize lead transport would minimize contamination of groundwater. Given stormwater runoff protection measures (e.g., implementation of the LID and SWPPP measures), operations associated with Alternative 2 would result in less than significant direct, long-term impacts to groundwater.

**Nearshore Waters**

Under Alternative 2, proposed operations would be in compliance with the stormwater runoff protection measures identified above that would also prevent direct impacts to the nearshore waters from stormwater runoff. Implementation of LID measures and BMPs under Alternative 2 would support the compliance with load allocations under the sediment TMDL for Ugum Watershed and ensure that stormwater runoff from the project area would not cause indirect impacts to nearshore waters in Talofofo Bay. Given stormwater runoff protection measures (i.e., implementation of LID, BMPs, and pollution prevention plans), operations associated with Alternative 2 would result in no direct or indirect long-term impacts to nearshore waters.

**Wetlands**

Under Alternative 2, proposed operations have the potential to cause indirect effects to nearby down-gradient wetland areas. However, the stormwater runoff protection measures identified above would also serve to protect water quality entering wetlands. Specifically, implementation of LID measures and the provisions of the SWPPP and associated erosion control activities would ensure that the stormwater runoff flowing into wetlands would be of acceptable quality. Given stormwater runoff protection measures (i.e., implementation of LID, BMPs, and pollution prevention plans), operations associated with Alternative 2 would result in less than significant direct or indirect long-term impacts to wetlands.

5.2.3 **Air Quality**

5.2.3.1 Affected Environment

The areas around the Alternative 2 are not developed and no sensitive populations are present. Ambient air quality conditions in these areas can be considered typical for a rural area and include few activities involving operation of major stationary or mobile sources.

5.2.3.2 Environmental Consequences

The construction activities associated with Alternative 2 would be similar to Alternative 1, with the exception of site location. Therefore, the predicted construction activity annual emissions would be the same as Alternative 1, as summarized in Table 5.1.3-2, and are well below the significance criterion of 250 tpy.

The hot-spot air quality impacts during both construction and operational phases would be similar to Alternative 1, as discussed in Section 5.1.3; resulting in less than significant short- and long-term hot-spot air quality impacts.

5.2.4 **Noise**

5.2.4.1 Affected Environment

The mountainous southern-central portion of Guam contains Fena Valley Reservoir and NAVMAG with very few people residing in adjacent areas southeast of NAVMAG. Due to the low population and few roads, the only noise source in the area is wind noise. Acoustically, this area would be typical of a rural or wilderness setting with ambient noise levels in this area between 35-45 dBA (USEPA 1978).
5.2.4.2 Environmental Consequences

Construction

There would be no impact due to construction noise under Alternative 2 because construction activities would be in an unpopulated area of Guam. Construction areas would be at least 1 mile (1.6 km) away from the nearest receptors.

Operation

Noise modeling results (Army 2013) for Alternative 2 are shown in Table 5.2.4-1 and Figure 5.2.4-1. Under Alternative 2, the Zone 2 noise levels cover approximately 227 acres (92 ha) beyond the boundaries of NAVMAG and Zone 3 affects about 13 acres (5.4 ha). The affected off-base acreage would extend towards the east and south of NAVMAG in the mountainous region of southern Guam. No houses lie within the noise contours, and therefore no residents would be affected by Zone 2 or Zone 3 noise contours. Table 5.2.4-1 lists the Noise Zones and the associated acreage affected within each zone.

Table 5.2.4-1. Noise Exposure within Noise Zones under LFTRC Alternative 2

<table>
<thead>

</table>

Note: Zone 1 is not listed because all land uses are compatible within Zone 1.

Under Alternative 2, no people would be impacted by Zone 2 or 3 noise levels because there are no residences within these zones. There would be no direct impacts due to live-fire training noise under this alternative because there would be no populated residential areas affected and none of the noise significance criteria stated in the Marine Corps Guidance memo for land use and noise exposure would be exceeded (Marine Corps 2005). There would be no direct or indirect impacts because no population would be affected, and none of the impact assessment criteria related to potential noise impacts would be exceeded. As described in Section 5.1.4.2, noise generated levels at the HG Range would remain within Andersen South and noise levels would not impact any residences. In summary, there would be no residences/households affected by noise resulting from implementation of Alternative 2 and, consequently, no significant noise impacts would occur.

In comparison, Alternative 1 is the only LFTRC alternative that would potentially result in significant noise impacts, so the significance of Alternative 2 noise impacts is less than Alternative 1 and the same as Alternatives 3, 4 and 5.
Figure 5.2.4-1
Small Arms ADNL Noise Zones for NAVMAG (East/West) LFTRC Alternative 2

Source: NAVFAC Pacific 2013
5.2.5  Airspace

5.2.5.1  Affected Environment

The overall existing airspace conditions for Alternative 2 would be the same as described for Alternative 1 (see Section 5.1.5.1). Detailed information on military and civilian air traffic associated with AAFB and Guam International Airport, respectively, is provided in the 2010 Final EIS (Volume 2, Chapter 7: Airspace, Section 7.1.2: Military Air Traffic, pages 7-8 to 7-10).

5.2.5.2  Environmental Consequences

Construction

No changes to airspace would be required during construction of the LFTRC under Alternative 2. Construction activities would not be expected to conflict or interfere with the use or management of existing airspace in the vicinity. Therefore, construction of the LFTRC under Alternative 2 would have no impact on airspace.

Operation

Figure 5.2.5-1 depicts the proposed Restricted Area associated with the Alternative 2. This SUA would be needed to contain the vertical hazard associated with the proposed live-fire training. Boundary coordinates for the proposed NAVMAG (East/West) Option C of R-7202 Guam would begin at:

- lat.13°20'55"N., long.144°40'34"E
- to lat.13°20'43"N., long.144°43'37"E
- to lat.13°18'54"N., long.144°43'40"E
- to lat.13°18'50"N., long.144°40'32"E
- to the point of beginning

Altitudes, times of use, and controlling and using agencies for this Restricted Area SUA would be the same as described in Section 5.1.5.2 for Route 15 LFTRC Alternative 1. The proposed CFA associated with the HG Range at Andersen South would be the same as described in Section 5.1.5.2 and depicted in Figure 5.1.5-4.

Section 3.5.3.1 identifies the potential impacts to airspace from implementation of the LFTRC alternatives. Given the location of the NAVMAG Complex, the proposed Alternative 2 would directly impact arrivals into and departures out of the Guam International Airport. The FAA stated in the preliminary Airspace Feasibility Assessment (FAA 2013) that Alternative 2 is not feasible. However, the FAA stated that “an assignment of ‘not feasible’ to a specific alternative is not a statement of infeasibility, but merely an assessment of the airspace in regard to the level of ‘assumed impact’ (FAA 2013).

Operational activities under Alternative 2 have the potential for significant direct, long-term impacts to aviation due to the following:

- Guam International Airport Airspace and instrument approach procedures.
- IFR/VFR traffic flows.
- Terminal operations.
Figure 5.2.5-1
Proposed SUA Associated with LFTRC Alternative 2

Legend
- DoD Property
- SUA Associated with LFTRC Alternative 2
- LFTRC Alternative:
  - NAVMAG (East/West) Alternative 2

Source: NAVFAC Pacific 2013
However, if this alternative is selected, long-term impacts and potential mitigation would be further studied through the DON/FAA/Air Force consultation process. The general types of potential mitigation measures that could be employed may include adjusting airspace per FAA coordination and/or adjusting LFTRC operation procedures if feasible. However, no potential mitigation measures are proposed at this time.

As detailed in Table 5.7-1, operational impacts under Alternative 2 would be the same as under Alternatives 1, 3, and 4. Operational impacts under Alternative 2 would be greater than impacts under Alternative 5.

5.2.6 Land and Submerged Land Use

5.2.6.1 Affected Environment

The affected environment for the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.6.1 of this SEIS.

The proposed Alternative 2 is partially located on the southern portion of NAVMAG and extends off-base to the east. The proposed land acquisition area is shown on Figure 5.2.6-1. In addition to the land required for the expanded NAVMAG installation boundary, land would be acquired for the access road connection to Route 4 (Figure 5.2.6-1). Most of the land proposed for acquisition is privately owned (Figure 5.2.6-1).

Additional details on the number of lots affected and land ownership is provided in Section 5.2.15, Socioeconomics and General Services. No submerged land is affected by this alternative (Figure 5.2.6-1).

The primary existing land uses for NAVMAG are munitions storage and administration, which occur in the northern portion of NAVMAG. There are existing training activities in NAVMAG including a sniper range, Ordnance Annex Detonation Range, land navigation areas, air training (search and rescue, insertion/extraction). Fena Valley Reservoir water wells are located central-west in NAVMAG. Some of these NAVMAG land uses are shown on Figure 5.2.6-1.

Land use is related to other resource areas that are covered under various sections of this SEIS, such as socioeconomic, recreational or ambient noise. Most of the land proposed for acquisition is undeveloped and in its natural state (Appendix D, SIAS; Figure 5.3-15, Table 5.3-3). There are no community land use plans for the NAVMAG vicinity. The GBSP land classification for the entire acquisition area is Agriculture (see Figure 3.6.1-2). However, as described in the Section 5.2.8, Terrestrial Biological Resources, the acquisition area is within the Guam Bolanos Conservation area, which is under Guam Department of Agriculture jurisdiction. USDA-designated prime and important farmlands were identified within the acquisition area (see Figure 5.2.5-1). No current agricultural use was identified.

Adjacent land uses to the Alternative 2 impacted area are other NAVMAG land uses and non-federal lands that are classified by GBSP as Agricultural (see Figure 3.6.1-2). Mount Lamlam and Mount Jumullong Manglo were identified west of the SDZs, but not adjacent (Figure 5.2.6-1).

The proposed action associated with Alternative 2 includes off-base utility infrastructure and a new access road, as described in Section 2.5.4.2 and summarized in Section 5.2.
Figure 5.2.6-1
Land Use in the Vicinity of NAVMAG (East/West) LFTRC Alternative 2

Sources: DON 2010, NAVFAC Pacific 2013
5.2.6.2 Environmental Consequences

Land use impacts are addressed in this section. Land ownership impacts are addressed in Section 5.2.15, Socioeconomics and General Services.

Construction

As previously discussed in Chapter 3, Section 3.6.3.1, Methodology, all changes in land use are considered long-term operational impacts. Therefore, there is no construction-phase analysis for this resource under any of the alternatives.

Operation

Potential impacts on Fena Valley Reservoir and water supply are addressed in the Section 5.2.2, Water Resources. The wellhead protection areas would not be affected. LFTRC land use would be compatible with the existing military NAVMAG land use, except the use of the southern land navigation area would be discontinued. Any direct or indirect land use incompatibility issues related to the military mission within NAVMAG would be resolved through application of installation master planning guidelines outlined in UFC 2-100-01. Therefore, long-term land use impacts would be less than significant.

The acquired area would largely remain as open space. USDA-designated prime and important farmlands were identified within the area but the area is not currently used for agriculture. The long-term loss of approximately 7% of the USDA-designated prime farmland and less than 1% of USDA-designated important farmland on Guam is an indirect adverse impact, but is considered less than significant because it is not currently in agricultural use and there are other prime and important farmlands available for agricultural use.

The proposed Alternative 2 would be compatible with surrounding vacant land use. Zone 3 noise contours would extend slightly off-base into vacant land, as described in the Section 5.2.4.2, Noise. Zone 2 noise contours would also extend beyond the proposed installation boundary, as shown on Figure 5.2.4-1. However, no existing or planned residential land uses (or other sensitive receptors like schools or medical facilities) were identified within the Zone 2 or 3 contours. The acquisition area is designated for Agriculture, which is a compatible land use within the Zone 2 and 3 noise contours. No land use impact due to noise was identified.

The proposed access road/utility easements are compatible with the current vacant land use and GBSP Agriculture classification. The new access road would facilitate public access to remote areas. This new access could be considered both a potential beneficial and adverse direct and long-term impact on adjacent and nearby land use. The landowners may appreciate improved access to their property, but they may also be concerned that a new roadway would facilitate public access.

As addressed in Section 5.2.10.2, Cultural Resources and Section 5.2.7.2, Recreational Resources, Mount Lamlam and Mount Jumullong Manglo public access would not be subject to additional restrictions.

Implementation of Alternative 2 would restrict non-DoD access to a portion of the Bolanos Conservation Area that would be within the land acquisition area. The impact of the reduced access on conservation goals and objectives is primarily a biological resources impact and is addressed in Section 5.2.8, Terrestrial Biological Resources. As described in Section 3.6.3, Approach to Analysis, new access restrictions placed on non-DoD populations is a potential direct and long-term significant impact when a specific community-valued land use is affected.
The following may be a potential mitigation measure to reduce this impact to a less than significant level:

- DoD would work with GovGuam to develop a plan to balance the loss of conservation land use and access with the operational needs and public safety concerns.

Alternatives 2 and 4 would have a similar level of impact to land use resources due to the loss of public access and valued land uses from the Bolanos Conservation Area. However, the significant impacts are potentially mitigable and would have less of an impact than Alternative 1, which has no mitigation proposed. Both Alternatives (2 and 4) would have a greater impact to land use than Alternative 3, which would have less than significant land use impacts.

### 5.2.7 Recreational Resources

#### 5.2.7.1 Affected Environment

The 2010 Final EIS described the proposed actions to occur at NAVMAG (Volume 2, Chapter 2, Section 2.3: Proposed Action-Training Functions and Section 2.3.1.3: Non-Firing General Military Skills Training Facilities, pages 2-41 to 2-43 and 2-44 to 2-55, respectively). These included proposed non-live fire training and maneuver facilities and operations, as well as the use of the existing hiking trails as an access road to the NAVMAG site. While the current proposed action for live-fire training ranges differs from the 2010 Final EIS actions at NAVMAG, the potentially impacted recreational environment and the recreational resources near NAVMAG remain the same. A list of recreational resources near NAVMAG is contained in the 2010 Final EIS (Volume 2, Chapter 9: Recreational Resources, Section 9.1.5: South, pages 9-14 to 9-18). Comprehensive descriptions of recreational resources near NAVMAG are contained in the 2010 Final EIS (Volume 9, Appendix G, Chapter 1: Recreational Resources, Section 1.4.1: Naval Munitions Site and Section 1.4.2: Non-DoD Land, pages G-1-19 to G-1-28). Access and use of the recreational resources within NAVMAG are restricted to base personnel and guests only. Recreational resources near Alternative 2 are identified in Table 5.2.7-1.

| Table 5.2.7-1. Recreational Resources within the Vicinity of Alternative 2 |
|---------------------------------------------------------|--------------------------------------------------|
| **Recreational Resource**                             | **Public Access**                                |
| Historic and Cultural Attractions                      |                                                 |
| Fena Massacre Site                                    | Installation personnel and guests only (open to the public for an annual memorial event) |
| **Scenic Points**                                     |                                                 |
| Japanese Lookout                                       | Installation personnel and guests only           |
| **Fishing**                                            |                                                 |
| Fena Reservoir                                         | Installation personnel and guests only           |
| **Parks**                                              |                                                 |
| Talofoto Falls Park and Hiking Trails on Non-DoD property | Open to the public                             |
| **Other**                                              |                                                 |
| Almagosa and Dobo Springs and Bonya                    | Installation personnel and guests only (and public by special request on a limited basis) |

Source: DON 2010.

Unlike the 2010 Final EIS NAVMAG action, this option includes ranges and SDZs extending outside NAVMAG property and to the east. The proposed access road would utilize the existing Dandan Road from Highway 4, run parallel to the northern boundary of the Dandan communications site, and then extend west to the ranges on improved all-weather roadways. This expanded footprint does not encompass any additional recreational resources within its boundaries not already described and analyzed in the 2010 Final EIS.
5.2.7.2 Environmental Consequences

**Construction**

Construction and/or improvement of access roads on non-federal property would be required to reach the east ranges in this alternative. Recreational resources would be directly affected primarily through possible short-term vehicle delays in reaching recreational sites, caused by earth-moving and construction vehicles. Although staged construction equipment would not obstruct access, or the use of, recreational resources, inconvenience to resource seekers (e.g., potential detours to be made, longer wait, and other similar inconveniences) would result. However, the impacts from this construction process would be short-term in nature, recreational opportunities would not be substantially reduced, and recreational resources would not experience direct physical deterioration as a result of implementing Alternative 2. Therefore, short-term less than significant impacts to recreational resources would be anticipated.

**Operation**

Portions of SDZs are proposed outside NAVMAG property and to the east. These parcels would need to be acquired and would become federally owned property. Therefore, access to the public would be limited. In addition to access restrictions, there are potential indirect impacts from firing range noise, which could lessen visitor enjoyment of publicly accessible recreational resources in the area of the LFTRC. Long-term direct impacts from limitations on public access and noise from firing ranges could result in significant impacts to recreation sites. However, direct and indirect long-term impacts would be less than significant for the following reasons:

- The 2010 Final EIS states that the impacts are less than significant at the NAVMAG site. Even though the current East/West and L-Shaped NAVMAG LFTRC alternatives extend eastward from NAVMAG and would require land acquisition, there are no identified recreational resources in those areas that would be directly or indirectly affected by land acquisition.
- The construction of the access road for the East/West and L-Shaped NAVMAG LFTRC alternatives would make access to the area easier for the public during those times the ranges are not in operation.
- Known recreational resources in the area (primarily Talofofo Falls) would not be impacted by noise during training.

5.2.8 Terrestrial Biological Resources

5.2.8.1 Affected Environment

**Vegetation Communities**

Figure 5.2.8-1 depicts the vegetation communities within non-federal lands and the southern NAVMAG associated with the proposed Alternative 2. The vegetation communities were mapped based on the following sources:

- USFS (2006) - island-wide coarse-scale mapping used as the starting point.
- Field surveys conducted in 2012 (NAVFAC Pacific 2013a) in notional range areas for more fine-scale mapping.
Figure 5.2.8-1
Vegetation Communities - NAVMAG (East/West) LFTRC Alternative

Sources: USFS 2006; NAVFAC Pacific 2013a
Vegetation types are described in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.1: Vegetation Communities, pages 10-1 to 10-77). The impacted areas (i.e., physical disturbance for range footprints) of Alternative 2 are located on non-federal lands and consist primarily of savanna vegetation interspersed with wetland vegetation associated with streams and drainages. Some barren areas (badlands) are also present. The area within the NAVMAG is associated with the SDZs of the proposed ranges and traverses savanna and patches of ravine forest (see Figure 5.2.8-1). The proposed access road from Highway 4 initially follows, for approximately 2.5 miles (4.0 km), a new 2-lane paved road (Dandan Road) that leads to the new Guam landfill. It then goes north and is routed through an area with no roads or trails and then joins an existing 4-wheel drive trail near the proposed Non-standard Small Arms Range. Vegetation communities along this proposed access road are shown on Figure 5.2.8-1.

Terrestrial Conservation Areas

The SDZs of the proposed ranges overlie established Overlay Refuge lands within NAVMAG and the northern portion of the GovGuam Bolanos Conservation Area (Figure 5.2.8-2). The conservation area was created to protect native flora and fauna in the interior of southern Guam and to support restoration efforts proposed in the Guam Comprehensive Wildlife Conservation Strategy (GDAWR 2006). It is managed by GDAWR for hunting and outdoor recreation. Historically, the area was predominantly ravine forest with very little savanna complex. However, humans and ungulates have changed the landscape through agricultural burning and browsing, and currently the Bolanos Conservation Area is nearly an even mix of savanna complex and ravine forest (GDAWR 2006; Natural Resources Conservation Service 2009).

Wildlife - Native Species

The only native migratory bird species observed during project-specific surveys within the proposed range areas on non-federal lands was the yellow bittern. General information on migratory birds for southern Guam that would be applicable for the area of proposed ranges associated with Alternative 2 is provided in the National Audubon Society’s Christmas Bird Counts for southern Guam (National Audubon Society 2013). From 2005 through 2011, a total of 37 species of native birds were reported and all are protected under the MBTA. Some of these species potentially occur within the action area, but most are found primarily in coastal areas. Species likely to use the action area are Pacific golden plover, tattlers, egrets, and yellow bittern. Surveys conducted in 2008-2010 and in 2013 on NAVMAG detected the following native species: Pacific golden-plover, white tern, yellow bittern, and gray-tailed tattler (NAVFAC Pacific 2010, 2013a, 2013b; JRM 2013).

The only native reptile species detected within the range footprints and associated buffer areas during surveys conducted for this SEIS was the Pacific blue-tailed skink (NAVFAC Pacific 2013a, 2013b).

The proposed Dandan access road to the proposed ranges on non-federal lands under Alternative 2 crosses the Bubulao River (Figure 5.2.8-1). Guam’s freshwater ecosystems have not been studied in detail and specific data is not available for the aquatic resources in streams that would be crossed or that are in the vicinity of the proposed ranges. Some information is available for southern Guam streams, such as the Talofofo Watershed, as noted in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.5.3: Naval Munitions Site - Freshwater Invertebrates and Fish, pages 10-77 to 10-78). This information is assumed to be generally applicable to other freshwater streams in southern Guam. All Guam indigenous freshwater fish are amphidromous (i.e., fish which move between fresh and salt water during some part of life cycle, but not for breeding). Aquatic fish and invertebrates observed in previous studies are listed in Table 5.2.8-1. Of those recorded, the flagtail, *Stiphodon* goby, and several species of invertebrates are designated as Guam SOGCN (GDAWR 2006).

Legend: *Guam SOGCN.
Sources: (1) Best and Davidson 1981; (2) GDAWR 2000; NAVFAC Pacific 2010.

Non-native bird species observed during recent surveys within the proposed range areas of Alternative 2 include the island collared dove, black francolin, and king quail (NAVFAC Pacific 2013a, 2013b).

Feral pigs and Philippine deer are common in ravine and savanna plant communities. Although pig rooting was observed in some perimeter areas of wetlands, habitat degradation in the open lands throughout the Alternative 2 action area is less than in forested areas (NAVFAC Pacific 2013a, 2013b).

The following non-native reptile and amphibian species were observed during surveys conducted for this SEIS within proposed range footprints and associated 328-foot (100-m) buffers: curious skink, marine toad, crab-eating frog, Hong Kong whipping frog, and Gunther’s Amoy frog (NAVFAC Pacific 2013a). In addition, brown treesnake are present in forested areas of the Alternative 2 action area.

Based on data from other streams in southern Guam, a variety of non-native fish species may potentially occur in streams within the Alternative 2 action area, particularly Bubulao River (GDAWR 2000; NAVFAC Pacific 2010) (see Table 5.2.8-1).

Special-Status Species: Federal ESA-Listed and Proposed Species

Two ESA-listed species (Mariana fruit bat and Mariana swiftlet) occur within the proposed Alternative 2 action area, including the proposed access road (Table 5.2.8-2 and Figure 5.2.8-3). Although “suitable habitat” for special-status species is present within the Alternative 2 project areas, the brown treesnake, the primary factor in the extirpation of special-status wildlife species on Guam and one of the largest obstacles to achieving recovery of special-status species, is still considered abundant and widespread on Guam. Until brown treesnakes are suppressed or removed from at least targeted areas on Guam, the habitat is not in a suitable condition to support the survival of special-status species due to current snake abundance on Guam (e.g., Guam Micronesian kingfisher, Guam rail, Mariana crow) (USFWS 2010a).
In addition to the discussion below, information for individual species occurring within NAVMAG is provided in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.5.3: Naval Munitions Site - ESA and Candidate Species, pages 10-79 to 10-84).

Legend: *E = endangered, NR = not reported, PE = proposed endangered, PT = proposed threatened, T = threatened.
Sources: (a) Jenkins 1983; (b) USFWS 1990; (c) COMNAV Marianas 2001; (d) GDWR 2006; (e) Brooke 2008; (f) Brooke and Grimm 2008; (g) Smith et al. 2008; (h) GovGuam 2009; (i) NAVFAC Pacific 2013a, 2013b; (j) USFWS 2008b; (k) USFWS 2009a; (l) USFWS 2009b; (m) USFWS 2011; (n) USFWS 2012a; (o) USFWS 2012c; (p) BirdLife International 2013; (q) JRM 2013; (r) USFWS 2010b; (s) USFWS 2014a, 2014b; (t) NAVFAC Pacific 2010.

MARIANA FRUIT BAT. After 1996, an estimated 5-20 individual Mariana fruit bats were thought to occur within the NAVMAG/Upper Talofoto Watershed, and were assumed to be full time residents of the area, rather than migrants from the main Pati Point Colony on AAFB in northern Guam (Morton and Wiles 2002). USFWS (1996) speculated that disturbance associated with illegal hunting may have inhibited the establishment of a communal roost within the NAVMAG. Although fruit bat recovery habitat occurs within the Alternative 2 action area, surveys within and in the vicinity of the proposed ranges on non-federal lands in 2012 did not observe any Mariana fruit bats (NAVFAC Pacific 2013a). The closest known observations of fruit bats are 3 miles (4.8 km) northwest of the proposed ranges within the NAVMAG (Figure 5.2.8-3). These observations are from surveys conducted in 2013 for this SEIS. Fruit bats are known to travel 6-7.5 miles (10-12 km) to reach forage areas (USFWS 1990), and the Alternative 2 action area contains fruit bat recovery habitat, particularly ravine forest primarily within the SDZ to the west of the range areas within the NAVMAG and to the south of the range areas (see Figure 3.8.3-1). Therefore, there is the potential for the fruit bats within the NAVMAG to occur within the Alternative 2 action area.

MARIANA COMMON MOORHEN. The moorhen is a freshwater obligate species and inhabits emergent vegetation in freshwater marshes and ponds. As described in the 2010 Final EIS, the largest moorhen population was historically at Fena Reservoir. However, conditions in the reservoir have changed, causing moorhens to find more suitable habitat elsewhere. The decrease in suitable habitat seems to be a result of the decline of Hydrilla verticillata, a water plant used by moorhens as a nesting substrate (JRM 2013). The current population on Guam is estimated at 100-150 birds (USFWS 2012b).

Although freshwater wetlands were common in the proposed non-federal lands range area, open water habitat was not observed in the impacted area during 2012 surveys. Stinson et al. (1991) observed four moorhens on a seasonal pond approximately 300 feet (90 m) north of the proposed MPMG Range boundary (Figure 5.2.8-3). During surveys in June 2012, this area was observed to be a dry, well-vegetated, elongated basin several hundred feet long. In addition, another dry, well-vegetated basin approximately 500 feet (150 m) west of the proposed MPMG Range impacted boundary was also observed. This basin is the headwater of the Sarasa River according to USGS hydrography data.
Figure 5.2.8-3
Special-Status Species Observations - All NAVMAG LFTRC Alternatives
MARIANA SWIFTLET. Swiftlets nest and roost in caves and leave the caves during the day to forage over a wide variety of terrain and vegetation, favoring ridge crests and open grassy areas where they capture small insects while flying (USFWS 1991). There are only three known nesting/roosting caves (Mahlac, Fachi, and Maemong) on Guam for this species and they are located in the northern NAVMAG approximately 2 miles (3.2 km) north of the non-federal lands range area (see Figure 5.2.8-3). The number of swiftlets at Mahlac cave fluctuates around 1,000, while the number at Maemong cave from 2010 to 2012 ranged between 40 and 126, and at Fachi cave have fluctuated between a low of 3 (2011) and a high of 172 (2009) (Brindock 2012).

During June and July 2012, surveys within the proposed non-federal lands range area observed 1-11 Mariana swiftlets at multiple locations from 4 survey stations (see Figure 5.2.8-3) (NAVFAC Pacific 2013a). All Mariana swiftlet observations were between 1.5 and 2.3 miles (2.4-3.7 km) from the three known nesting/roosting caves in the northeastern portion of NAVMAG.

MARIANA CROW. The Mariana crow was last observed in southern Guam in the mid-1960s (USFWS 2005). Since 2009, the population on Guam consisted only of two males on AAFB, occurring primarily within the MSA (USFWS 2009c). However, as of 2012, the Mariana crow is considered extirpated in the wild on Guam (Personal communication via letter from USFWS, Pacific Islands Fish and Wildlife Office, Honolulu, HI regarding the DON NOI for Proposed Placement of LFTRC on Guam NWR; December 7, 2012). The closest population of crows is on the island of Rota, approximately 56 miles (90 km) north of Guam. Crows in northern Guam used primary limestone forest for nesting, with nests exclusively in native trees. They have been observed foraging in both primary and secondary limestone forests and tangantangan (USFWS 2005). Crow recovery habitat is found within proposed project impacted areas and SDZs associated with Alternative 2 (see Figure 3.8.3-1).

GUAM RAIL. The Guam rail was last seen in southern Guam in the 1970s, and was extirpated in the wild by 1985. It exists primarily in captivity on Guam and in mainland zoos. Experimental populations of Guam rails were introduced onto Rota, CNMI in 1989 and onto Cocos Island, off the southern coast of Guam, in 2011 (USFWS 2009b; BirdLife International 2013). The Guam rail prefers edge habitats, especially grassy or secondary vegetation areas which provide good cover; mature forest is deemed only marginal for the Guam rail (USFWS 2009b). Rail recovery habitat is found within proposed project impacted areas and SDZs associated with Alternative 2 (see Figure 3.8.3-2).

GUAM MICRONESIAN KINGFISHER. The Guam Micronesian kingfisher was last seen in southern Guam in the 1970s, and was extirpated in the wild by 1988. It is now found only in captivity on Guam and at mainland zoos (USFWS 2008). Kingfishers utilized a wide variety of habitats including primary and secondary limestone forest, strand forest, coconut forest, edge habitats, and forest openings, but mature forests with tree cavities suitable for nesting may be an important requirement for kingfisher reproduction (USFWS 2008). Kingfisher recovery habitat is found within proposed project impacted areas and SDZs associated with Alternative 2 (see Figure 3.8.3-1).

SLEVIN’S SKINK. Originally found on Guam, Cocos Island, Rota, Tinian, Guguan, Alamagan, Asuncion, and Maug, it is now limited to Cocos Island, Sarigan, Guguan, Alamagan, Pagan, and Asuncion. Slevin’s skink has not been recorded on Guam since 1945 and is believed to be extirpated from Guam; it is now known to occur only on Cocos Island (an atoll south of Guam) (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 2. Therefore, as Slevin’s skink is not found within the impacted areas of Alternative 2, this species is not addressed further.
Tree Snails. The three proposed endangered tree snail species (Guam tree snail, humped tree snail, and fragile tree snail) were not observed during field surveys conducted within the proposed range footprints on non-federal lands in 2012 in support of this SEIS (NAVFAC Pacific 2013a, 2013b). Although suitable tree snail habitat occurs within the SDZs, the SDZ areas would not be subject to any ground-disturbing activities and proposed range construction and operations would not impact tree snails. Therefore, as the tree snail species are not found within the impacted areas of Alternative 2, these species are not addressed further.

Serianthes. The endangered Serianthes tree was not observed during field surveys conducted within the proposed range footprints on non-federal lands in 2012 in support of this SEIS (NAVFAC Pacific 2013a, 2013b). The only known location on Guam of the Serianthes tree is on AAFB, more than 20 miles (32 km) north of the NAVMAG. However, Serianthes recovery habitat is found within proposed project impacted areas and SDZs associated with Alternative 2 (see Figure 3.8.3-2).

Heritiera Longipetiolata. This endemic tree is found in crevices of rough limestone in primary limestone forest. Although there are two records of the species on the NAVMAG (see Figure 5.2.8-3), it was not observed during surveys in support of this SEIS and there are no records of the species within the impacted areas of Alternative 2, nor is there suitable habitat within the impacted areas; suitable habitat only occurs within the SDZs of the proposed ranges (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as H. longipetiolata is not found within the impacted areas of Alternative 2, this species is not addressed further.

Tabernamontana Rotensis. There are no records of T. rotensis within the NAVMAG (USFWS 2014) and the species was not observed during surveys in support of the 2010 Final EIS and during 2012 in support of this SEIS nor is there suitable habitat within the impacted areas; suitable habitat only occurs within the SDZs of the proposed ranges (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as T. rotensis is not found within the impacted areas of Alternative 2, this species is not addressed further.

Cycas Micronesica. The cycad is found in limestone forests throughout Guam and is proposed as an endangered species under the ESA because of the Asian cycad scale insect that is devastating the species. This species has not been observed within the NAVMAG or non-federal lands associated with Alternative 2, nor is there suitable habitat within the impacted areas; suitable habitat only occurs within the SDZs of the proposed ranges (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as C. micronesica is not found within the impacted areas of Alternative 2, this species is not addressed further.

Bulbophyllum Guamense. An epiphyte in the orchid family, this species occurs in mat-like formations on tree branches of coastal lowland/limestone forests. Currently there are 8 known occurrences on Guam, totaling fewer than 250 individuals (USFWS 2014a, 2014b). There are no records of the species within the impacted areas of Alternative 2, nor is there suitable habitat within the impacted areas; suitable habitat only occurs within the SDZs of the proposed ranges (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as B. guamense is not found within the impacted areas of Alternative 2, this species is not addressed further.

Dendrobium Guamense. An epiphyte in the orchid family, this species occurs on tree branches of coastal lowland/limestone forests. Currently, there are 4 known occurrences on Guam with fewer than 250 individuals (USFWS 2014a, 2014b). There is one known occurrence within the NAVMAG within the vicinity of Almagosa Springs (Figure 5.2.8-3). There are no records of the species within the impacted areas of Alternative 2, nor is there suitable habitat within the impacted areas; suitable habitat only occurs within the SDZs of the proposed ranges (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b).
Therefore, as *D. guamense* is not found within the impacted areas of Alternative 2, this species is not addressed further.

**Eugenia bryani.** A perennial shrub in the myrtle family, the species is known only from the island of Guam. Historically, *E. bryani* is known from windy exposed coastal clifflines and along the Pigua River, in lowland/limestone forests. Currently, *E. bryani* is known from 6 occurrences totaling fewer than 420 individuals (USFWS 2014a, 2014b). There are no records of the species within the impacted areas of Alternative 2, nor is there suitable habitat within the impacted areas; suitable habitat only occurs within the SDZs of the proposed ranges (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *E. bryani* is not found within the impacted areas of Alternative 2, this species is not addressed further.

**Maesa Walkeri.** A shrub or small tree in the primrose family typically found in limestone forests, this species is known from only two individuals on Guam, one of which is located along the southwestern border of the NAVMAG (Figure 5.2.8-3) (USFWS 2014a, 2014b). There are no records of the species within the impacted areas of Alternative 2, nor is there suitable habitat within the impacted areas; suitable habitat only occurs within the SDZs of the proposed ranges (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *M. walkeri* is not found within the impacted areas of Alternative 2, this species is not addressed further.

**Nervilia Jacksoniae.** A small herb in the orchid family, this species is found in lowland/limestone forests. On Guam, *N. jacksoniae* is known from 2 occurrences totaling fewer than 200 individuals (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 2, nor is there suitable habitat within the impacted areas; suitable habitat only occurs within the SDZs of the proposed ranges (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *N. jacksoniae* is not found within the impacted areas of Alternative 2, this species is not addressed further.

**Psychotria Malaspiniae.** A shrub or small tree in the coffee family, this species is found in lowland/limestone forests. Currently, *P. malaspiniae* is known from five occurrences. None of these individuals have been observed within the last 5 years (USFWS 2014a, 2014b). There are no records of the species within the impacted areas of Alternative 2, nor is there suitable habitat within the impacted areas; suitable habitat only occurs within the SDZs of the proposed ranges (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *P. malaspiniae* is not found within the impacted areas of Alternative 2, this species is not addressed further.

**Solanum Guamense.** A small shrub in the nightshade family that occurs within limestone forests. Currently, *S. guamense* is known from a single occurrence of one individual on Guam (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 2, nor is there suitable habitat within the impacted areas; suitable habitat only occurs within the SDZs of the proposed ranges (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *S. guamense* is not found within the impacted areas of Alternative 2, this species is not addressed further.

**Tinospora Homosepala.** A vine in the moonseed family found in limestone forests. Currently, *T. homosepala* is known from 3 occurrences totaling approximately 300 individuals (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 2, nor is there suitable habitat within the impacted areas; suitable habitat only occurs within the SDZs of the proposed ranges (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *T. homosepala* is not found within the impacted areas of Alternative 2, this species is not addressed further.
**TUBEROLABIUM GUAMENSE.** An epiphyte in the orchid family found in limestone forests. Currently, *T. guamense* is known from three occurrences on Guam: one occurrence in the forest ecosystem of the Mt. Almagosa cliffline, one occurrence south of the swiftlet caves on the NAVMAG, and one in the northeastern area of Finegayan (see Figure 5.2.8-3) (NAVFAC Pacific 2010; USFWS 2014a, 2014b). There are no records of the species within the impacted areas of Alternative 2, nor is there suitable habitat within the impacted areas; suitable habitat only occurs within the SDZs of the proposed ranges (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *T. guamense* is not found within the impacted areas of Alternative 2, this species is not addressed further.

**HEDYOTIS MEGALANTHA.** A perennial herb in the coffee family, this species occurs in savanna areas in southern Guam. Currently, *H. megalantha* is known from one large scattered occurrence totaling fewer than 1,000 individuals on southern Guam, between Mt. Alutom and Tarzan Falls. This species typically occurs as lone individuals rather than in patches or groups (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 2 (USFWS 2014b). Therefore, as *H. megalantha* is not found within the impacted areas of Alternative 2, this species is not addressed further.

**PHYLANTHUS SAFFORDII.** This woody shrub is currently known from four scattered occurrences on southern Guam within savanna areas: Mt. Alutom, Piti Hills, Nimitz Hill “War in the Pacific Lookout,” and near the Cetti Bay Watershed (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 2 (USFWS 2014b). Therefore, as *P. saffordii* is not found within the impacted areas of Alternative 2, this species is not addressed further.

**Special-Status Species: Guam-Listed Species and SOGCN**

Three Guam-listed species (Pacific slender-toed gecko, moth skink, and the tree fern *Cyathea lunulata*) were not observed during field surveys conducted within the proposed impacted areas on non-federal lands in 2012 in support of this SEIS, nor is there suitable habitat within the impacted areas (NAVFAC Pacific 2013a, 2013b). Suitable habitat only occurs within the SDZs of the proposed ranges. The SDZs would not be subject to any ground-disturbing activities and proposed range operations would not impact the Pacific slender-toed gecko, moth skink, and the tree fern *Cyathea lunulata*. Therefore, as the Pacific slender-toed gecko, moth skink, and the tree fern *Cyathea lunulata* are not found within the impacted areas of Alternative 2, these species are not addressed further.

5.2.8.2 Environmental Consequences

**Construction**

*Vegetation.* The majority (62%) of the impacted areas for the proposed ranges and access road on non-federal lands under Alternative 2 is dominated by savanna (250 acres [101 ha]), with an additional 58 acres (24 ha) of secondary limestone forest and ravine forest, 18 acres (7 ha) of herbaceous wetland, and 68 acres (27 ha) of developed/agriculture/barren areas (Table 5.2.8-3 and see Figure 5.2.8-1).
### Table 5.2.8-3. Direct Construction-Related Impacts to Vegetation Communities with Implementation of LFTRC Alternative 2

<td><strong>19.4 (7.9)</strong></td>
</tr>
</tbody>
</table>

**Legend:** SLF = secondary limestone forest; RF = ravine forest; HW = herbaceous wetland; HS = herbaceous scrub; Sav = savannah; Dev = developed; Ag = agriculture; Bar = barren.

The area that would be directly impacted from construction of the proposed ranges on non-federal lands under Alternative 2 is composed of vegetation communities that are common across Guam (Guam Department of Agriculture 2010; USFS 2006). Based on surveys conducted in 2012 in the proposed range areas, the ravine forest community is significantly degraded in many areas by invasion of non-native woody plant species including *Vitex* and betelnut palm, and heavy infestation by herbaceous non-native invasive plants (NAVFAC Pacific 2013a). Impacts to vegetation from construction of the proposed HG Range at Andersen South were discussed in Section 5.1.8.2 and were found to be less than significant. Therefore, there would be less than significant impacts to vegetation with implementation of the construction activities under Alternative 2.

However, the following BMPs may be implemented to avoid and reduce potential direct, long-term impacts of proposed construction activities on vegetation communities with implementation of LFTRC Alternative 2.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the contractor education program.
- **Onsite Vegetation Waste Management Procedures.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the vegetation waste management procedures.
- **DON Guam Landscaping Guidelines.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of landscaping guidelines.
- **LFTRC Range Berm Controls.** To manage stormwater runoff and control erosion, LFTRC range berms would contain native or non-invasive herbaceous vegetation and other engineering controls.
- **Contractor Plans and Specifications.** All construction would occur within the limits of construction shown in the project figures.

**Terrestrial Conservation Areas.** Only the SDZs associated with the proposed ranges would overlie a portion of Overlay Refuge lands and the Bolanos Conservation Area. As the SDZs would not be subject to any ground-disturbing activities associated with proposed range construction, there would be no impacts to Overlay Refuge lands or the Bolanos Conservation Area with implementation of the construction activities under Alternative 2.
Wildlife - Native Species. The loss of 405 acres (164 ha) of common vegetation communities within southern Guam would result in less than significant impacts to regional native wildlife species. Short-term construction noise may temporarily impact suitable habitat for native birds in the vicinity of the construction areas, but they would relocate to other areas of suitable habitat in the vicinity, and could return to the area following construction. Impacts to wildlife from the construction of the HG Range at Andersen South were discussed in Section 5.1.8.2 and would be less than significant. Implementation of Alternative 2 would not have a significant adverse effect on a population of any migratory bird species or other native wildlife species. Non-listed native reptiles are abundant throughout Guam and impacts to vegetation communities under Alternative 2 would result in less than significant impacts to non-listed native reptile populations.

Proposed construction activities and associated movement of materials onto and off of Guam could increase the potential for the spread of existing or introduction of new non-native invasive species. To prevent the inadvertent spread of non-native species on Guam or to other locations off of Guam, the DON will implement standard biosecurity measures (e.g., HACCP, brown treesnake interdiction measures, coconut rhinoceros beetle vegetation management procedures, outreach/education, and monitoring to evaluate effectiveness of HACCP) into construction protocols, procedures, and activities.

The following BMPs would be implemented to avoid and minimize potential direct, long-term impacts of proposed construction activities on native wildlife with implementation of Alternative 2.

Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of Biosecurity Outreach and Education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Onsite Vegetation Waste Management Procedures.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the vegetation waste management procedures.
- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

With implementation of these BMPs, including development of HACCP plans and ongoing implementation of standard DON biosecurity protocols regarding detection and management of non-native species (e.g., coconut rhinoceros beetle), the potential for the introduction of new or spread of existing non-native species on Guam is substantially reduced. Therefore, there would be less than significant impacts to native wildlife species related to the potential introduction and establishment of non-native species with implementation of proposed construction activities associated with Alternative 2.

**Special-Status Species: Federal ESA-Listed and Proposed Species**

Impacts to special-status species from the construction of the proposed HG Range at Andersen South were discussed in Section 5.1.8.2 and were determined to be less than significant. The following discussion addresses those species that occur within the impacted areas (ranges and access road) on non-federal lands under Alternative 2.
MARIANA FRUIT BAT. Approximately 43 acres (17 ha) of Mariana fruit bat recovery habitat would be removed due to proposed construction activities under Alternative 2. This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

Field surveys conducted in 2012 on the non-federal lands did not detect any Mariana fruit bats in the vicinity of the proposed firing ranges. This area is almost entirely open land with small, isolated ravine forest areas. The species is currently limited to the few areas on Guam away from human activities and with suitable habitat, primarily on federal lands on the NAVMAG and AAFB (JRM et al. 2012a, 2012b; JRM 2013; A. Brooke, NAVFAC Marianas, personal communication). However, illegal hunting, loss and degradation of native forest, predation by the brown treesnake, and the increased extirpation risk owing to the high vulnerability of very small populations continue to limit the potential recovery of the species on Guam (USFWS 2010a; JRM 2013). Based on the equilibrium/carrying capacity of snakes on Guam (Rodda and Savidge 2007), implementation of the proposed action is not expected to increase the likelihood of predation by the brown treesnake on Mariana fruit bats.

Additional potential direct temporary impacts to the Mariana fruit bat from construction activities are based on the distances from those activities that are likely to cause disturbance to this species (e.g., noise, human activity, lighting). The evaluation of fruit bat disturbance is based on the approach used by USFWS in previous ESA section 7 formal consultations and associated BOs (e.g., USFWS 2006, 2010). For the fruit bat these distances are: roosting habitat within 492 feet (150 m) and foraging habitat within 328 feet (100 m) from the activity (Wiles, personal communication 2006 and Janeke, personal communication 2006, respectively, as cited in USFWS 2006).

The loss of 43 acres (17 ha) of fruit bat recovery habitat on Guam would not preclude the recovery or survival of the fruit bat, and it would not substantially reduce the total number of bats that the island can support. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to the Mariana fruit bat with implementation of proposed construction activities associated with Alternative 2.

The following BMPs may be implemented to avoid and reduce potential direct long-term impacts of proposed construction activities on Mariana fruit bats and recovery habitat with implementation of Alternative 2.

Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Pre-Construction Surveys.** Surveys would be completed within suitable fruit bat habitat 1 week prior to onset of construction activities following the USFWS-approved JRM protocol. If a fruit bat is present within 492 feet (150 m) of the project site, the work must be postponed until the bat has left the area.
- **Lighting Installation.** Lighting would be designed to meet minimum safety and AT/FP requirements. Hooded lights would be used to the maximum extent practicable at all new
roads and facilities adjacent to fruit bat habitat. Illumination of forest would be kept to an absolute minimum.

MARIANA CROW. The Mariana crow is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the crow is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the crow, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the crow is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative 2, impacts to the crow would be limited to recovery prospects. If crows are reintroduced and exposed to construction activities under Alternative 2, they may be disturbed (DON 2014).

Although the crow no longer occurs on Guam, approximately 43 acres (17 ha) of crow recovery habitat would be removed due to proposed construction activities associated with Alternative 2. This area is included in the impacts to vegetation discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

This loss of crow recovery habitat on Guam would not preclude the recovery or survival of the crow, and it would not substantially reduce the total number of crows that the island can support. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to the Mariana crow with implementation of proposed construction activities associated with Alternative 2. If and when the crow is reintroduced to Guam, the best available information indicates project-related noise would not further reduce the amount of recovery habitat suitable for this species' breeding, feeding and sheltering (USFWS 2010a).

The following BMPs may be implemented to avoid and reduce potential direct long-term impacts of proposed construction activities on Mariana crow recovery habitat with implementation of Alternative 2.

Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

GUAM RAIL. The Guam rail is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the rail is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the rail, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the rail is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative 2, impacts to the rail would be limited to recovery prospects. If rails are reintroduced and exposed to construction activities under Alternative 2, they may be disturbed (DON 2014).
Although the rail no longer occurs on Guam, approximately 49 acres (20 ha) of rail recovery habitat would be removed due to proposed construction activities under Alternative 2. This area is included in the impacts to vegetation discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

This loss of rail recovery habitat on Guam would not preclude the recovery of the rail, and it would not substantially reduce the total number of rails that the island can support. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to the rail with implementation of proposed construction activities associated with Alternative 2.

The following BMPs may be implemented to avoid and reduce potential direct and indirect long-term impacts of proposed construction activities on the recovery of the Guam rail with implementation of Alternative 2.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

**GUAM MICRONESIAN KINGFISHER.** The Guam Micronesian kingfisher is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the kingfisher is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the kingfisher, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the kingfisher is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative 2, impacts to the kingfisher would be limited to recovery prospects. If kingfishers are reintroduced and exposed to construction activities under Alternative 2, they may be disturbed (DON 2014).

Although the kingfisher no longer occurs on Guam, approximately 43 acres (17 ha) of kingfisher recovery habitat would be removed due to proposed construction activities associated with Alternative 2. This area is included in the impacts to vegetation discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

This loss of kingfisher recovery habitat on Guam would not preclude the recovery of the kingfisher, and it would not substantially reduce the total number of kingfishers that the island can support. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to the kingfisher with implementation of proposed construction activities associated with Alternative 2.

The following BMPs may be implemented to avoid and reduce potential direct long-term impacts of proposed construction activities on kingfisher recovery habitat with implementation of Alternative 2.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.
• **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.

• **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

**MARIANA SWIFTLET.** Based on 2012 field surveys, this species forages in the proposed range area, particularly in the northern portion, closer to the only known swiftlet nesting/roosting caves on Guam. The conversion of 399 acres (162 ha) of vegetation communities commonly found throughout southern Guam (e.g., herbaceous scrub/savanna, ravine forest, and developed/agricultural/barren) to the proposed ranges and access road would not diminish the amount of swiftlet foraging habitat within the area. Swiftlets would continue to forage within the extensive foraging habitat surrounding the proposed range area, including the extensive areas of savanna and ravine forest to the north, west, and east of the proposed range areas, and areas in the vicinity of the nest/roost caves on NAVMAG and the drainages of the Mahlac, Maagas, and Talofofo rivers (see Figures 5.2.8-1 and 5.2.8-3). The proposed construction activities would also not impact regional insect populations that are the prey base for the swiftlet. Although noise levels within the immediate vicinity of proposed construction activities would increase, they would be localized and temporary. Proposed construction activities would not impact the swiftlet nesting/roosting caves approximately 2 miles (3 km) to the north of the proposed ranges. Therefore, there would be less than significant impacts to the Mariana swiftlet with implementation of the proposed range construction activities under Alternative 2.

**MARIANA COMMON MOORHEN.** Although no suitable open water habitat currently occurs within the area of the proposed ranges under Alternative 2, moorhens were reported from a seasonal pond just to the west of the proposed KD Pistol Range in 1991. During surveys in June 2012, this area was observed to be a dry, well-vegetated basin. Even if sufficient rain fell in future years that would result in ponding of this area, the extensive vegetative growth would preclude the availability of open water and prevent moorhens from using this area. The only other suitable moorhen habitat is located at Fena Valley Reservoir, approximately 1.5 miles (2.4 km) to the northwest of the proposed ranges. However, in accordance with proposed BMPs (see Section 2.8), pre-construction surveys within the proposed construction area for moorhens will be conducted 1 week before construction activities begin to ensure that open water habitat does not occur and moorhens are not within the impacted areas. Therefore, there would be no impacts to the Mariana common moorhen with implementation of the proposed range construction activities under Alternative 2.

**SERIANTHES TREE.** Although individual *Serianthus* trees do not occur within the impacted areas of Alternative 2, approximately 18 acres (7 ha) of *Serianthus* recovery habitat would be removed due to proposed construction activities. This area is included in the impacts to vegetation discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

This loss of *Serianthus* recovery habitat on Guam would not preclude the recovery of *Serianthus*, and it would not substantially reduce the total number of *Serianthus* that the island can support. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to *Serianthus* with implementation of proposed construction activities associated with Alternative 2.
The following BMPs may be implemented to avoid and minimize potential direct long-term impacts of proposed construction activities on the recovery of *Serianthes* with implementation of Alternative 2.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2, *Construction, Vegetation* for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, *Construction, Vegetation* for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, *Construction, Vegetation* for a detailed description of the contractor education program.

**Special-Status Species: Guam-Listed and SOGCN**

The only Guam-listed species that would occur within the proposed range areas are also listed under the federal ESA and were discussed above.

**Operation**

*Vegetation.* With implementation of BMPs (see previous discussion of construction impacts under *Vegetation*), including ongoing implementation of standard DON and commercial biosecurity protocols (e.g., Port of Guam, A.B. Won Pat International Airport) regarding detection and management of non-native species, invasive species outreach and education, 1-year post construction monitoring to evaluate effectiveness of HACCP, and applicable elements of the SIP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of Alternative 2 is considered unlikely.

Fire potential would increase due to proposed live-fire range operations. Fire can result in direct effects to vegetation by increasing erosion, allowing for the establishment of non-native species, and altering wildlife habitat by reducing food resources, breeding habitat, and shelter. Native plants and their habitats on Guam are adapted to a humid, tropical climate and are not adapted to a fire driven ecosystem (USFWS 2008a). Fire is a serious problem on Guam. Fire history records available from 1979 - 2002 indicate that over this 23-year period more than 16,000 fires have occurred in Guam (averaging more than 700 per year) that have burned in excess of 100,000 acres (40,469 ha), primarily in southern Guam. Of these 16,000 fires, 477 of them occurred on Naval Base Guam, primarily at Apra Harbor and NAVMAG, burning more than 9,800 acres (3,966 ha) (Nelson 2008).

As a BMP and in accordance with range safety protocols, a Range Fire Management Plan would be prepared, based on the DON’s Wildland Fire Management Plan (Nelson 2008) (see Section 2.8). It would include protocols for monitoring fire conditions and adjusting training as needed (e.g., certain types of training may be disallowed under certain fire conditions), and location and management of firebreaks, fire-fighting roads, and a fire fighting water system. Units undergoing training would be briefed on requirements suitable to the conditions of the day and protocols should a fire occur (e.g., specifying how the range would shut down and how fire suppression action would be taken). With implementation of the Range Fire Management Plan, which establishes management and fire suppression and emergency response procedures, potential impacts from range-related wildfires would be less than significant. The USFWS concluded in their BO for the 2010 Final EIS that they anticipated that no additional vegetation would be lost due to wildfires igniting as a result of proposed live-fire training operations (USFWS 2010a). Therefore, there would be less than significant impacts to vegetation from operation of LFTRC Alternative 2.
Terrestrial Conservation Areas. While the modeled noise levels from proposed range operations may be heard within the southern portion of NAVMAG on Overlay Refuge lands and within the northern portion of the Bolanos Conservation Area (see Figures 5.2.8-2 and 5.2.8-4), the noise levels would be approximately 55-64 dB ADNL or less and would be barely perceptible above ambient noise levels for the region (see Section 5.2.4, Noise). Signs would be posted along the perimeter of the SDZ notifying the public of an active live-fire range within the area behind the signs and access is restricted during operations. The Bolanos Conservation Area is remote, difficult to access, limited to use by hikers and hunters, and management is minimal (GDAWR 2006). Therefore, proposed operations at the proposed Alternative 2 would result in less than significant impacts to management or conservation values of Overlay Refuge lands or the Bolanos Conservation Area.

Wildlife - Native Species. Based on field surveys in support of this SEIS, the abundance and diversity of native wildlife within the area of the proposed Alternative 2 range area is low, primarily due to the prevalence of the savanna vegetation community. Noise associated with proposed live-fire range operations may impact native wildlife in the vicinity of the ranges. However, noise associated with similar live-fire operations at ranges in Hawaii has not resulted in significant impacts to wildlife in the vicinity of those ranges (Army 2009, 2013a). Implementation of Alternative 2 would not have a significant adverse effect on a population of migratory bird species or other native wildlife species. Impacts to wildlife from the operation of the HG Range at Andersen South were discussed in Section 5.1.8.2 and there would be less than significant impacts.

With implementation of BMPs (see previous discussion of construction impacts under Vegetation), including ongoing implementation of standard DON and commercial biosecurity protocols (e.g., Port of Guam, A.B. Won Pat International Airport) regarding detection and management of non-native species, invasive species outreach and education, applicable elements of the SIP, and 1-year post-construction monitoring to evaluate effectiveness of HACCP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of the proposed LFTRC under Alternative 2 is considered unlikely. The DON recognizes the USFWS’ ongoing concern regarding potential spread of the brown treesnake. The DON will consult with USFWS under ESA section 7 to determine if additional brown treesnake interdiction measures are warranted and applicable. In addition, lighting associated with the range and support areas would be hooded or shielded to the maximum extent practicable to prevent unnecessary light beyond operational areas. Therefore, there would be less than significant impacts to native wildlife with operation of proposed LFTRC Alternative 2.

Special-Status Species: Federal ESA-Listed and Proposed Species

MARIANA FRUIT BAT. The assessment of noise levels associated with the proposed HG Range at Andersen South was previously discussed in Section 5.1.8.2. There would be no impacts to Mariana fruit bats from noise associated with operation of the HG Range.

For those species of fruit bats that have been tested for hearing sensitivity, their audiograms are very similar to those of humans, with similar upper and lower frequency limits and hearing threshold levels (Calford et al. 1995; Heffner et al. 2006; Koay et al. 1998). Therefore, it is likely that noise from live-fire operations at the proposed ranges would be heard by fruit bats as it would be heard by humans.

Note: Species observations are historical sightings over multiple years and multiple surveys and do not represent the current population status or distribution of species within the depicted area.
The USFWS established 60 dB and 93 dB as two thresholds of biological significance based on their review of impacts of noise to wildlife. Noise levels above 60 dB have been found to affect acoustic communication, breeding biology, survival of young, and non-auditory bird and mammal physiology. Noise levels above 93 dB may temporarily or permanently affect hearing (USFWS 2010a). No species would be exposed to noise levels of 93 dB or greater under the proposed action. While noise levels may approach 93 dB in the immediate vicinity of the firing of an individual weapon, fruit bats or other wildlife species would not be in proximity to the live-fire event given the location and nature of weapons firing within a developed range area.

Responses to noise can vary among individuals as a result of habituation where after a period of exposure to a stimulus, an animal stops responding to the stimulus. In general, a species can often habituate to human-generated noise when the noise is not followed by an adverse impact. Even when a species appears to be habituated to a noise, the noise may produce a metabolic or stress response (increased heart rate results in increased energy expenditure) though the response may or may not lead to changes in overall energy balance. Anthropogenic noise disturbance is known to alter animal behavioral patterns and lead to population declines (Barber et al. 2011; Francis and Barber 2013; McGregor et al. 2013).

In addition to noise level, the frequency and regularity of the noise also affect species sensitivity. That is, different types of noise sources will produce different effects on different species. Noise from aircraft overflights may not produce the same response from a wildlife species as noise from a land-based noise source such as a vehicle, chainsaw, or gun shot. Wildlife species often do not react only to a noise source but more importantly to the visual component associated with that noise source. Nesting birds will react to a noise source by tilting their head, becoming alert, etc. but often do not leave the nest or perch until there is a visual connection with the noise source. For example, birds may not react to just the sound of a chainsaw, but when that sound is coupled with a human walking near the bird, the bird will flush. This is also shown in reactions by various species to aircraft overflights (airplanes and helicopters). An overflight with just a sound component does not elicit a strong response, but if an animal hears and then sees the aircraft, the bird will more likely flush and move away (Manci et al. 1988; USFWS 1992; Krausman et al. 1993; Bowles 1995). In other words, human intrusions near roost sites, nests, foraging areas, etc. (e.g., timber harvesting, hiking, hunting) are readily detectable and substantial (USFS 1992).

Species that are commonly hunted often demonstrate behavioral (e.g., flushing, startle response) or physiological responses (e.g., increased heart rates, increased respiration rates) to gunshot sounds (Larkin et al. 1996). Knight et al. (1987) found that American crows nesting in urban areas were less wary of people than American crows nesting in rural habitat and attributed the difference to the hunting of rural crows. Barron et al. (2012) found that American crows avoided areas with live-fire exercises in a similar fashion and suggested that species hunted by humans will be more adversely affected by human activity, including military training (e.g., live-fire training) than species that are not hunted.

As stated by Morton and Wiles (2002), “Poaching is a particularly insidious activity because not only does it impact fruit bats through mortality, it reinforces behavioral avoidance of humans. Consequently, roosting or foraging fruit bats that might not otherwise be disturbed by some human activities … may become unduly sensitized to them because of illegal hunting.” Based on observations on Guam and Rota, fruit bats have abandoned areas where hunting has occurred and did not return even though no further hunting or gunshots occurred within the area for months after (Janeke 2006; AAFB 2008b; USFWS 2009a; Mildenstein and Mills 2013). In addition, anecdotal evidence from numerous individuals who have conducted fruit bat research on Guam and the CNMI for many years indicate that fruit bats do avoid areas that have been previously subjected to hunting and also areas that experience live-fire activities (G.
Wiles, Washington Department of Fish and Wildlife, personal communication, 2014; T. Mildenstein, University of Montana, personal communication, 2014; D. Janeke, HDR, Inc., personal communication, 2014; N. Johnson, Marianas Conservation Unlimited, personal communication, 2014). For example, during fruit bat monitoring at AAFB near the CATM range as part of a larger study monitoring the effects of aircraft overflights on fruit bats and crows (JRM et al. 2012b), N. Johnson observed flying fruit bats avoid the CATM range by 300–400 m when live-fire operations were being conducted (N. Johnson, Marianas Conservation Unlimited, personal communication, 2014).

However, a species can also habituate to human-generated noise when the noise is not followed by an adverse impact. While fruit bats may avoid an area subjected to hunting and the associated gun shots, fruit bats, like most wildlife species, will also learn that if a disturbance or sound does not produce an adverse effect (e.g., mortality), then they can habituate to that disturbance or sound and will not show an adverse reaction (e.g., flying away, avoiding the area) (Boyle and Samson 1985; Francis and Barber 2013).

Most of the effects of noise are mild enough that they may never be detectable as variables of change in population size or population growth against the background of normal variation (Bowles 1995). Other environmental variables (e.g., predators, weather, changing prey base, ground-based disturbance) may influence reproductive success and confound the ability to identify the ultimate factor in limiting productivity of a certain species, area, or region (Smith et al. 1988).

Based on identified recovery habitat for the Mariana fruit bat (USFWS 2010b), noise levels of 60 dB ADNL and greater would overlie 824 acres (333 ha) of recovery habitat in the vicinity of Alternative 2 (Table 5.2.8-4).

Given the ongoing poaching of fruit bats on Guam, it is likely that those fruit bats that currently occur on Guam will avoid areas of live-fire training as they may have experienced a poaching event. While there is the potential for eventual habituation by fruit bats to LFTRC live-fire activities, fruit bats are expected to initially avoid areas of live-fire training activities. Therefore, fruit bats may temporarily avoid approximately 824 acres (333 ha) of recovery habitat due to proposed live-fire range operations. However, proposed live-fire operations at the LFTRC are not continuous and would occur between 7:00 a.m. and 7:00 p.m., for 39 weeks per year, and night operations (estimated to occur 2 nights per week over 39 weeks per year) would occur between 7:00 p.m. and 10:00 p.m. or 6:00 a.m. and 7:00 a.m. In addition, live-fire operations would not physically impact recovery habitat. This temporary avoidance of recovery habitat on Guam would not preclude the recovery or survival of the fruit bat, and it would not substantially reduce the total number of fruit bats that the island can support.

With implementation of BMPs (see previous discussion of construction impacts under Vegetation), including ongoing implementation of standard DON and commercial biosecurity protocols (e.g., Port of Guam, A.B. Won Pat International Airport) regarding detection and management of non-native species, invasive species outreach and education, applicable elements of the SIP, and 1-year post-construction monitoring to evaluate effectiveness of HACCP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of Alternative 2 is considered unlikely. Therefore, there would be less than significant impacts to the Mariana fruit bat with implementation of proposed operational activities associated with Alternative 2.
MARIANA CROW, GUAM RAIL, AND GUAM MICRONESIAN KINGFISHER. These species are extirpated and no longer present on Guam, due primarily to predation by the brown tree snake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of these species is reasonably certain to occur and the species are likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of these species, nor successful suppression of the brown tree snake to a level which would support re-introduction. Until the crow, rail, and kingfisher are successfully re-introduced and then have the potential to be exposed to operational activities under Alternative 2, there would be no impact to these species. If the species are reintroduced and exposed to LFTRC operational activities under Alternative 2, they may be disturbed.

MARIANA SWIFTLET. Based on surveys conducted for this SEIS, swiftlets were observed within what would be the proposed 75-79 dB ADNL and less noise contours associated with the proposed ranges under Alternative 2 (see Figure 5.2.8-4). Although the specific hearing ability of the Mariana swiftlet is not known, they are expected to be able to hear as well as most birds, which are sensitive to sounds from 100 hertz to 8-10 kilohertz (Dooling 1980). Therefore, they are able to hear the sounds associated with live-fire ranges. Although foraging swiftlets may avoid areas within the proposed ranges with the highest noise levels (e.g., 79 dB ADNL), the total area within this contour would be approximately 300 acres (121 ha). Swiftlets would continue to forage within the extensive foraging habitat surrounding the proposed range area, including the areas of savanna and ravine forest to the north, west, and east of the proposed range areas, and areas in the vicinity of the nest/roost caves on the NAVMAG and the drainages of the Mahlac, Maagas, and Talofofo rivers (see Figures 5.2.8-1 and 5.2.8-3). The proposed range operations would not impact regional insect populations that are the prey base for the swiftlet. In addition, swiftlets are generally more actively foraging in the early morning and late evenings before and after proposed range operations. As swiftlets do not have a history of being hunted, they would not have the same aversion to gunfire that Mariana fruit bats have and, therefore, may not avoid areas of live-fire range operations. Proposed range operations and associated noise would not impact the swiftlet nesting/roosting caves approximately 2 miles (3.2 km) to the north of the proposed ranges. Therefore, given the limited area (approximately 300 acres [121 ha]) that may be potentially avoided by foraging swiftlets, the extensive remaining foraging habitat within the surrounding areas that would still be available for foraging, and that swiftlets would still forage in the mornings and evenings before and after range operations, there would be less than significant impacts to the Mariana swiftlet due to proposed range operations under Alternative 2.

MARIANA COMMON MOORHEN. The modeled 55 dB ADNL noise contour overlies the southern portion of Fena Valley Reservoir. Moorhens primarily use the northern portion of the reservoir, near the spillway, for nesting, feeding and resting (Brooke and Grimm 2008; Brindock 2012). Given the low modeled noise level that may occur within the southern portion of the reservoir (i.e., 55 dB ADNL is approximately equal to ambient noise levels; see Section 3.4, Noise), and that moorhens predominantly use the northern portion of the reservoir that would be outside the 55-dB contour, there would be less than significant impacts to Mariana common moorhens with implementation of the proposed range operations under Alternative 2.

SERIANTHES TREE. Serianthes does not occur within the Alternative 2 action area. Although fire potential could increase due to proposed live-fire range operations, with implementation of the proposed Range Fire Management Plan and procedures (see Vegetation above, and Section 2.8), potential impacts from range-related wildfires on Serianthes would be less than significant. Therefore, there would be less than
significant impacts to *Serianthes* or recovery habitat due to proposed range operations under Alternative 2.

*Special-Status Species: Guam-Listed and SOGCN*

The only Guam-listed species that would occur within the proposed range areas are also listed under the federal ESA and were discussed above.

### 5.2.9 Marine Biological Resources

#### 5.2.9.1 Affected Environment

The Alternative 2 proposed project area is entirely inland, with no marine in-water or coastal components. Therefore, there is no marine biological resources affected environment for Alternative 2.

#### 5.2.9.2 Environmental Consequences

No in-water construction, dredging, or training activities, and/or land-based construction activities proposed under Alternative 2 would directly or indirectly affect the marine environment. Therefore, no direct or indirect impacts are expected.

Scoping comments for this SEIS noted concern regarding the possibility that contamination could migrate from the ranges through stormwater runoff. However, as discussed in Section 5.2.2, Water Resources, there would be no impacts to nearshore waters through implementation of surface water protection measures (i.e., compliance with Construction General Permit requirements and implementation of BMPs during construction and implementation of LID features in accordance with the DoD UFC LID (UFC 3-210-10) and Section 438 of the EISA, range maintenance BMPs, and pollution prevention plans during operations).

### 5.2.10 Cultural Resources

#### 5.2.10.1 Affected Environment

The following discussion summarizes previous cultural resources studies and known historic properties and other cultural resources within the PDIA and PIIA associated with Alternative 2.

The Alternative 2 area, also known as NAVMAG (East/West), is located both within the far southeast portion NAVMAG and just outside the NAVMAG to the east on lands owned by the GovGuam and by private landowners. As early as December 1944, miles of roads and magazines were constructed at the NAVMAG and the area was commissioned on February 22, 1945 (Mason Architects and Weitze Research 2009). During a limited expansion in the Korean conflict of the early 1950s, most of the present main administration buildings and many of the magazines were designed and built as part of the permanent base development program for Guam.

The affected environment for cultural resources associated with Alternative 2 is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 12: Cultural Resources, Section 12.1.5.1: Naval Munitions Site, pages 12-33 to 12-37). This description of the affected environment is updated here with new information from recent archaeological and architectural investigations conducted for this SEIS and other projects. To determine whether site information is from previous investigations (such as the 2010 Final EIS or other cultural resource studies) or prepared during in-fill studies conducted for this SEIS, refer to dates in the reference column in each table for the archaeological sites. Certain information about built properties (such as date and function) was derived from INFADS.
Portions of the Alternative 2 PDIA and PIIA were surveyed for the presence of cultural resources for the original proposed action (2010 Final EIS). Those and other previous investigations in the area included archaeological surveys (Henry et al. 1998; Hunter-Anderson and Moore 2002), a reconnaissance survey (Dye et al. 1978), architectural surveys (Mason Architects and Weitze Research 2010; Welch 2010), and TCP studies (Griffin et al. 2010). Additional investigations conducted for this SEIS included intensive cultural resource inventories in the PDIA and reconnaissance inventories in PIIA for this SEIS (Dixon et al. 2015a, 2015b). Note: due to changes in the alternative as a result of the SEIS planning process, 109.5 acres (44.32 ha) in the PDIA and 65.49 acres (26.5 ha) in the PIIA were added for Alternative 2 after the surveys were conducted. These 175 acres (70.82 ha) were examined through historic materials, aerials, and a comparison with adjacent areas to assess impacts to cultural resources. Collectively, these investigations provide the comprehensive inventory of cultural resources for Alternative 2.

As described in Section 5.1.10.1, the HG Range would be located at Andersen South under all of the LFTRC alternatives. This entire area was previously surveyed at an intensive level (Welch 2010; Dixon et al. 2011a).

During October through December 2014, the DON consulted with the parties to the 2011 PA and the public on the Draft TRRA. Consistent with Stipulation V.C of the 2011 PA, the TRRA provided planning level information on potential direct and indirect effects to historic properties within areas that may be selected in the Navy’s ROD for the live-fire training range complex. The Draft TRRA included information on the locations, orientations, and designs of each proposed LFTRC location. In addition to receipt of written comments, DON cultural resources professionals conducted three consultation sessions with the parties to the PA to discuss the analysis. The DON will take all comments into account in preparing the Final TRRA, which is planned for publication shortly after this Final SEIS. Comments and considerations developed during the Draft TRRA consultation process have been incorporated in this Final SEIS and informed the Draft RMP, as required by Stipulation V.C.4 of the 2011 PA.

Cultural Resources in the Alternative 2 PDIA

Alternative 2 would involve the construction of individual ranges, support buildings, and an access road. This construction area comprises the PDIA. Table 5.2.10-1 lists ten known archaeological sites located within the Alternative 2 PDIA within the NAVMAG. They include seven artifact scatters and two sites with latte components, all of which are eligible for listing in the NRHP, and one small artifact scatter that is not considered eligible for listing in the NRHP. No historic properties have been identified in the PDIA of the proposed HG Range at Andersen South.

**Legend:** GHPI = Guam Historic Properties Inventory; NRHP = National Register of Historic Places; NRHP criterion D = eligible for potential to yield information important in prehistory or history.

**Notes:**
1. Not all sites recorded within the project areas have received official GHPI numbers, although they have been documented as part of previous surveys.
2. Sites are in both the PDIA and the PIIA.
5. The Guam SHPO concurs with this recommendation (Guam SHPO correspondence dated August 22, 2013 [RC2013-0853]).

There are no known buildings or structures located in the PDIA for Alternative 2.

No TCPs have been identified in the PDIA for this alternative.

**Cultural Resources in the Alternative 2 PIIA**

The PIIA comprises SDZs for the LFTRC and HG ranges and associated areas potentially affected by increases in noise. It includes no locations of potential direct impact due to construction. Table 5.2.10-2 summarizes the 102 known archaeological sites within the Alternative 2 PIIA. Seventy-three sites are eligible for listing in the NRHP, including Pre-Contact artifact scatters, latte sites, and rockshelters. Twenty-nine sites, consisting of Pre-Contact artifact scatters and latte sites, have not been evaluated for listing in the NRHP. Should this alternative be selected, final assessments would be determined consistent with the procedures in the 2011 PA.

Legend:  NRHP = National Register of Historic Places; NA=not applicable; NRHP criterion D = eligible for potential to yield information important in prehistory or history.

Note:  ** Revised to match Guam GHPI forms dated May 28, 2014.

There are no known buildings or structures within the PIIA for Alternative 2.

A portion of one high density latte environ (an area with a high density of archaeological sites containing latte stones) that has been identified as a potential TCP is located within the PIIA.

5.2.10.2 Environmental Consequences

Construction

Construction activities associated with Alternative 2 have the potential to adversely affect historic properties and impact culturally important natural resources. Final determinations of effect would follow the procedures in the 2011 PA. Following is a discussion of potential direct and indirect effects to historic properties and impacts to culturally important natural resources.

Construction of the ranges, support facilities, and utilities would primarily occur in the south-central portion of Guam east of the NAVMAG (see Figure 2.5-3). Given the substantial development anticipated in the PDIA, it is assumed for purposes of this analysis that 100% of the area would be disturbed. Nevertheless, design alternatives to avoid and minimize adverse effects would be considered, consistent with procedures in the 2011 PA. No construction would occur in the PIIA.

Excavation and soil removal associated with the construction of Alternative 2 could adversely, directly affect nine known historic properties, including Pre-Contact artifact scatters and sites containing latte components (see Table 5.2.10-1). Seven of the historic properties are located within both the PDIA and the PIIA. Direct impacts to these sites would only occur to the portion within the PDIA. There is also a potential for NRHP-eligible archaeological sites in the 109.5 acres (44.32 ha) of unsurveyed areas within
the PDIA. No NRHP-eligible or unevaluated buildings or structures would be adversely affected by construction.

Construction activities associated with Alternative 2 have the potential to directly impact culturally important natural resources. The 2011 PA contains measures for coordinating with the SHPO and concurring parties to contact traditional natural healers, herbal practitioners and traditional artisans regarding identification and disposition of these important resources prior to construction (see 2010 Final EIS, Volume 2: 2-10; Volume 9, Appendix G, Chapter 4).

No historic properties or culturally important natural resources are anticipated in conjunction with utility upgrades that would be associated with Alternative 2. The modification or replacement of existing underground power lines adjacent to Dandan Road and the placement of water and wastewater lines adjacent to power lines would not affect any known cultural resources. There are no NRHP-eligible properties or culturally important natural resources located in the areas planned for water or wastewater utility upgrades or electrical utilities to support Alternative 2.

There are no historic properties located in the PDIA or PIIA for the proposed HG Range at Andersen South. Therefore, no adverse effects to historic properties are anticipated due to construction of the HG Range.

Operation

Operations associated with Alternative 2 could cause indirect adverse effects to historic properties as discussed below. Final determinations of effect would follow the procedures in the 2011 PA. Following is a discussion of potential adverse effects of operations associated with Alternative 2.

The potential for direct effects within the SDZ would be limited to the risk of strikes from stray rounds during Alternative 2 operations. The risk of such effects occurring is extremely low. The range would be designed to contain live fire inside the range itself to minimize the probability of rounds landing in the SDZ. Additionally, if a stray round were to escape the range, the chance of it hitting a historic property is remote, given the size of the SDZ and dispersal of historic properties. For these reasons, the potential for direct adverse effects as a result of range operations is de minimis.

Indirect adverse effects to NRHP-eligible archaeological sites from the operation of Alternative 2 could result from changes affecting site integrity. For many types of archaeological sites (i.e., ceramic scatters, rock alignments), auditory impacts associated with live-fire operations would not affect characteristics that qualify them for the NRHP. An increase in noise associated with live-fire operations may adversely affect historic properties for which solitude, quiet, or contemplation contribute to or define their significance, such as TCPs.

Under Alternative 2, small arms live-fire noise would be audible near 1 NRHP-eligible and 21 unevaluated sites that are located within the expanded noise contours (Table 5.2.10-3). Average noise levels during range operations are projected to increase from current levels of approximately 45 dB to between 65 dB and 85 dB ADNL due to the introduction of small arms live-fire noise (see Section 5.2.4, Noise). Eighteen of the unevaluated sites are Pre-Contact artifact or ceramic scatters, while four sites (one NRHP-eligible and three sites unevaluated for listing in the NRHP) contain latte components. Auditory impacts associated with range operations would not adversely affect the integrity of the 18 unevaluated artifact or ceramic scatters. Changes to the setting of two NRHP-eligible sites with latte components could be adverse (Table 5.2.10-3). There may also be an indirect effect to two unevaluated sites with latte components. If this alternative were selected, final assessments would be determined consistent with procedures in the 2011 PA.
### Table 5.2.10-3. Summary of Archaeological Sites Potentially Affected by Noise

**Legend:** NRHP = National Register of Historic Places; NA = not applicable; NRHP criterion D = eligible for potential to yield information important in prehistory or history.

**Note:** ** Revised to match Guam GHPI forms dated May 28, 2014.

No indirect adverse effects from visual intrusions associated with Alternative 2 are anticipated as the ranges would not be visible from most sites and the action would not involve a change in visual setting.

Access to all sites within the PIIA would be restricted during range operations; however, most of these sites are located within areas that currently have limited access due to operations at the NAVMAG or their remote locations. Members of the public have requested to visit areas of the NAVMAG in the past and there is a process to access certain areas. Therefore, indirect impacts could result from additional restriction on access to one potential TCP (a high density area of latte sites). The 2011 PA requires development of plans for regular public access to historic properties for DoD-controlled lands on Guam, subject to considerations including, but not limited to, public interest, public safety concerns and protocols, installation security, and emergency situations.

### Summary of Impacts and Potential Mitigation Measures

Implementation of Alternative 2 could cause direct, adverse effects to nine known NRHP-eligible archaeological sites. Potential indirect adverse effects could occur to two NRHP-eligible sites with latte components and two unevaluated archaeological sites with latte components. One potential TCP could also be indirectly affected by reduced accessibility. In addition, culturally important natural resources could be directly impacted due to removal of limestone forest and savanna vegetation.

Under this alternative, adverse short-term effects from construction would be more than under Alternative 1, but fewer than Alternatives 3, 4, and 5. If this alternative were selected, final assessments would be determined consistent with the procedures identified in the 2011 PA. Adverse effects from operation could occur, but would be fewer than for Alternatives 3, 4, and 5. Refer to Section 5.7, Table 5.7-1 for a comparison of cultural resources impacts and potential mitigation measures for each LFTRC alternative.

The 2011 PA, as discussed in Section 3.1.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. Broadly, the 2011 PA includes processes to share information, consider views of the public, and develop mitigation measures when historic properties may be adversely affected. The 2011 PA provides measures for mitigating adverse effects to NRHP-eligible or listed archaeological sites, consulting on new projects and initiating additional identification efforts, and resolving impacts due to loss of access to potential TCPs or culturally important natural resources.

More specifically, the 2011 PA established a process for the review and analysis of potential effects to historic properties and other cultural resources for all alternative LFTRC locations. During October through December 2014, the DON consulted with the parties to the PA and the public on the TRRA, which provided information about cultural resources potentially affected by the LFTRC alternatives carried forward in the SEIS, consistent with PA Stipulation V.C. The TRRA provides information on...
potential adverse effects resulting from the construction and operation of the selected LFTRC alternative to support consultation with the PA parties and the public. The DON will take all comments into account before reaching a final decision. For any alternative selected in the ROD, the 2011 PA stipulates that an RMP will be prepared to address effects from the construction and operation of the ranges. The RMP, developed in consultation with the consulting parties, will stipulate measures to avoid, minimize, and mitigate adverse effects to historic properties.

To the degree possible, direct and indirect impacts to historic properties and natural resources of cultural importance would be avoided or minimized during the planning process. Consultation under the 2011 PA would address potential adverse effects and alternatives to avoid adverse effects. Refer to Section 3.10 for more information on definitions and procedures. If avoidance is not possible, Table 5.2.10-4 presents potential mitigation measures to resolve adverse effects to historic properties and reduce impacts to cultural resources resulting from the implementation of Alternative 2. With the implementation of these measures and processes as outlined in the 2011 PA, it is expected that direct and indirect, short- and long-term impacts, as defined under NEPA, could be reduced to a level below significance.

5.2.11 Visual Resources

5.2.11.1 Affected Environment

The 2010 Final EIS describes the proposed activities at NAVMAG (Volume 2, Chapter 2: Proposed Action and Alternatives, Section 2.3.1: Requirements, page 2-49). Although Alternative 2 differs from the 2010 Final EIS activities at NAVMAG, the potentially affected visual environment and the visual resources themselves would remain the same. A list and description of visual resources at the NAVMAG is provided in the 2010 Final EIS (Volume 2, Chapter 13: Visual Resources, Section 13.1.4.1: Naval Munitions Site, pages 13-54 to 13-75). NAVMAG is located in a large, bowl-shaped valley with a water reservoir (Fena Reservoir) near its center. This reservoir is the largest freshwater body on Guam, and it provides a substantial amount of the island’s potable water supply. Like the rest of NAVMAG, the Fena Reservoir is not accessible to the public.
As noted in the 2010 Final EIS, the valley is surrounded by rugged terrain and several mountain peaks. Current NAVMAG facilities are almost entirely out of the public’s view. Views from within the northern portion of NAVMAG are a blend of a naturally appearing landscape, interspersed with areas of earth-covered magazines and ordnance storage facilities. The southern portion of NAVMAG has mountainous topography and a rugged terrain. With the exception of some trails for off-road vehicles, almost no human-made features cover the landscape.

Implementation of Alternative 2 would involve acquisition of land to the east that is outside existing NAVMAG boundaries, and primarily has a natural landscape, as shown in Photo 5.2.11-1.

**Photo 5.2.11-1: View looking east across NAVMAG near the top of the Lamlam Trail**

*Source: AECOM 2009.*

5.2.11.2 Environmental Consequences

Impacts on visual resources from Alternative 2 would be the same as those provided in the 2010 Final EIS (Volume 2, Chapter 13: Visual Resources, Section 13.2-7: Summary of Impacts, pages 13-80 to 13-82). Table 13.2-5 in the 2010 Final EIS noted that no visual impacts would occur from implementing either the ammunition storage alternatives or the access road alternatives. Although the actual footprint and type of development for Alternative 2 would be different from that originally analyzed in the 2010 Final EIS, the visual impacts, or lack thereof, would remain the same.

**Construction**

During construction, activities and equipment would cause temporary view obstructions where recognized views currently exist. These direct visual impacts during the construction phase would be short-term and would be less than significant.

**Operation**

Once the proposed action is operational, visual resources would not be greatly affected because of the undulating topography that interrupts views into NAVMAG, the use of existing trails for access to Alternative 2, the limited scale of proposed development, and the lack of visibility of the Alternative 2
area from Mount Lamlam, which is a National Landmark, and Mount Jumullong Manglo Overlook. Views towards the east from the publicly accessible Jumullong Manglo Overlook into NAVMAG, including views to those areas to be acquired, would not be substantially affected. Direct, long-term visual impacts would be less than significant.

5.2.12  Ground Transportation

5.2.12.1  Affected Environment

The affected environment for ground transportation resources under Alternative 2 includes transportation facilities internal to the site (range roadways and intersections). This section discusses existing conditions and assesses how the operations and construction of Alternative 2 would potentially affect transportation conditions for roadways and intersections internal to the site. Impacts to off-base (external) roadways and intersections are summarized in Section 6.1 of this SEIS.

5.2.12.2  Environmental Consequences

Construction

Potential construction impacts to ground transportation under Alternative 2 would be the same as those described in Section 4.1.12.2 for Alternative A. Potential direct and indirect impacts to ground transportation resources from construction would be minimized with implementation of appropriate work zone traffic management strategies and BMPs. Therefore, there would be less than significant short-term impacts to on-base (internal) roadways.

Operation

Proposed access to Alternative 2 would be from Route 4 and existing roadways would be used wherever possible. However, this alternative requires the construction of an access road to allow all-weather operations. The proposed access road would utilize the existing Dandan Road from Route 4, run parallel to the northern boundary of the Dandan communications site, and then extend west to the ranges on improved all-weather roadways. Potential operational impacts for Alternative 2 would be the same as those described in Section 5.1.12.2 for Alternative 1; there would be no direct, long-term significant impacts to internal (range) roadway segments or intersections.

5.2.13  Marine Transportation

5.2.13.1  Affected Environment

Alternative 2 and SDZ would not extend over waters used by vessels. Thus, there would be no marine transportation in the proposed area.

5.2.13.2  Environmental Consequences

Implementation of Alternative 2 would not impact open waters used by vessels. Therefore, it is expected that there would be no impact to marine transportation due to the construction and operation of Alternative 2.

5.2.14  Utilities

5.2.14.1  Affected Environment

The affected environment for the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.14.1 of this SEIS.
Electrical Power

Electric power in the vicinity of Alternative 2 is supplied by a local GPA power distribution system. This system is buried underground within the existing Dandan Road, near the beginning of the proposed new access road. This system has 3-phase 13.8 kV service buried power lines, as well as manholes along Dandan Road. The distribution system primarily serves the Dandan communication installation and the Layon Landfill. There is currently no electrical power system at the specific areas for the proposed Alternative 2 facilities.

Potable Water

The potable water system near Alternative 2 includes a local GWA water distribution system buried underground in the existing Dandan Road, at the beginning of the proposed new access road. This system consists of underground water lines and manholes along Dandan Road, primarily serving the Dandan communication installation and the Layon Landfill. There is currently no water distribution system at the specific areas for the proposed Alternative 2 facilities.

Wastewater

The wastewater utility near Alternative 2 consists of an existing GWA underground wastewater collection system in the existing Dandan Road, at the beginning of the proposed new access road. This system consists of underground sewer lines and manholes along Dandan Road, primarily serving the Dandan communication installation and the Layon Landfill. There are currently no wastewater utility systems at the specific areas for the proposed Alternative 2 facilities.

Solid Waste

There are no solid waste facilities near Alternative 2. The Layon Landfill is located on Dandan Road past the beginning of the proposed new LFTRC access road. Dandan Road is the primary haul route for trash trucks going to this landfill.

Information Technology and Communications

There is no DoD IT/COMM infrastructure near Alternative 2. There are buried commercial IT/COMM lines along Dandan Road, but none in the specific areas of the proposed Alternative 2 facilities.

5.2.14.2 Environmental Consequences

Potential impacts to existing utilities from operation of the HG Range would be the same as discussed in Section 5.1.14.2.

Electrical Power

The proposed electrical system improvements for Alternative 2, as described in Sections 2.5.4.2 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The electrical power requirements of the LFTRC facilities would be small (less than 50 kW), and thus would have minimal impact on the current system or current power customers. During construction, there would be direct, short-term impacts on current customers consisting of potential limited power outages during construction. Power outages would be addressed through construction phasing or the use of temporary generators where necessary, which would minimize downtime.

The long-and short-term direct impact of Alternative 2 on the electrical utility would be less than significant, both during construction and in operation, because upgrades would be installed to accommodate the increased demand.
Potable Water

The proposed water system improvements for Alternative 2, as described in Sections 2.5.4.2 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The Range Maintenance Building and the KD Rifle/KD Pistol Range Administrative Building are the only LFTRC facilities requiring water service. A fire hydrant would also be provided for filling range fire fighting vehicles and general fire protection. The potable water demand of the LFTRC would be very small, estimated at an average daily demand of 26,520 gallons per day (100,389 liters per day). Therefore, a less than significant, direct long-term impact would occur to the current system. During construction, minor water service outages could occur as new water lines are connected to existing water lines. With careful planning these potential outages would be minimized.

The short- and long-term direct impacts of Alternative 2 on the potable water utility would be less than significant, during both during construction and in operation, because improvements would be made to meet the increased demand.

Wastewater

The proposed wastewater collection system improvements for Alternative 2, as described in Sections 2.5.4.2 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The only LFTRC facilities that would generate wastewater would be the Range Maintenance Building and KD Rifle/KD Pistol Range Administrative Building that have an estimated wastewater flow of less than 0.01 MGd (0.038 MLd). Due to the length required for a sewer line (approximately 7,710 feet [2,350 m]), the need for two pump stations, and proximity to Fena Reservoir; a holding tank has been recommended. This tank would be located adjacent to the Range Maintenance Building between the MPMG and Non-standard Small Arms Ranges. The holding tank would have to be pumped out periodically, and its contents taken to one of the existing WWTPs for treatment and disposal. A holding tank of 35,000 gallons (132,000 liters) would need to be emptied about once per week. The estimated sewer flow demand would be minimal and not impact other wastewater resources.

All other LFTRC facilities, including the HG Range, would be provided with portable toilets. These toilets would require periodic emptying, with the sewage then being taken to one of the existing WWTPs for treatment and disposal. The estimated sewage amount would be minimal and would not impact the current other wastewater resources.

The direct short- and long-term impacts from Alternative 2 on the wastewater utility systems would be less than significant, both during construction and in operation, because upgrades and portable facilities would be installed to meet the increased demand.

Solid Waste

The proposed solid waste improvements for Alternative 2, as described in Sections 2.5.4.2 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The estimated solid waste generation for LFTRC operations is small and this additional solid waste would not impact current waste collection, handling, or disposal operations. Suitable solid waste collection containers would be provided where required. The solid waste would be periodically collected, handled, and transported to the main cantonment transfer station for processing and disposal. The impact to solid waste from operations of Alternative 2 would be the same as discussed in Section 5.1.14.2 for Alternative 1.

Impacts to the solid waste handling effort during the U&SI construction phase involving the generation of green waste and C&D debris waste would be the same as discussed in Section 5.1.14.2 for Alternative 1.
The direct short- and long-term impact to solid waste from Alternative 2 would be less than significant, both during construction and in operation, because the additional waste volume would not exceed disposal capacity, and procedures for collection and transport would be established.

Information Technology and Communications

The proposed IT/COMM infrastructure improvements for Alternative 2, as described in Section 2.6, have been developed to meet the requirements for the proposed action. Since there are no existing IT/COMM resources near Alternative 2, there would be no impacts to existing IT/COMM services. New duct banks in Alternative 2 that would need to be installed include a duct bank of six 4-inch (10-cm) conduits interconnecting the LFTRC range facilities, including the HG Range. There would be inter-base connectivity required for DoD IT/COMM, as discussed in Section 2.6. Some of these inter-base connections in the southern part of Guam would require new rights of way.

The direct short- and long-term impact to the IT/COMM utility from Alternative 2 would be less than significant, both during construction and in operation, because upgrades would be installed to accommodate the increased demand.

5.2.15 Socioeconomics and General Services

Most issues and impacts associated with socioeconomics and general services encompass the entire proposed action (i.e., cantonment/family housing and LFTRC development, increased population), and do not vary with site alternatives. Accordingly, the impact discussion in Section 4.1.15 of this SEIS applies for all of the LFTRC alternatives and is incorporated here by reference. Land acquisition, however, is unique to the LFTRC alternatives, and the amount of land to be acquired varies by alternative. Therefore, this section focuses exclusively on the socioeconomic and sociocultural issues and impacts associated with the acquisition of land under Alternative 2 (with the exception of the HG Range, which would not require land acquisition).

5.2.15.1 Affected Environment

Table 5.2.15-1 displays baseline data for land that would be acquired for Alternative 2. A total of 1,894 acres (766.5 ha) of land would be acquired by the federal government. Most of the land (1,498 acres, 606 ha) is privately owned, including 17 of the 19 lots that would potentially be acquired. GovGuam owns 360 acres (146 ha) in a single lot that would be acquired under this alternative. One additional lot that would be acquired has unknown ownership.

Table 5.2.15-2 shows existing land use in the NAVMAG (East/West) acquisition area. Land use on the NAVMAG East/West parcel consists of 1,498 acres (606 ha) of undeveloped land and 396 acres (160 ha) of conservation land (a portion of the Bolanos Conservation Area), where development is not allowed. The GBSP land classification for the entire acquisition area is Agriculture. However, as described in the Land Use Section 5.2.6, no current agricultural use was identified. None of the acreage currently has a productive economic use.

With regard to the affected fiscal environment of Guam, as stated in Section 5.1.15, GovGuam collected a total of $20.1 million in property tax revenues. These revenues accrue to the GovGuam general fund.

5.2.15.2 Environmental Consequences

The DON is required to comply with federal land acquisition laws and regulations, which include the requirement to offer just compensation to the owner, to provide relocation assistance services and benefits to eligible displaced persons, to treat all owners in a fair and consistent manner, and to attempt first, in all instances, acquisition through negotiated purchase. Specific policies and procedures, including the Uniform Act, are described in detail in Section 5.1.15.2.

While the government is authorized to acquire property through its powers of eminent domain (condemnation), it has been the consistent policy of the DON to acquire real estate through negotiation with owners. Even with a negotiated sale or lease however, “friendly” condemnation may be necessary to clear problems with title. The DON would comply with all applicable laws and regulations, including the Uniform Act.

In general, assuming voluntary sale or lease of property and conformance with land acquisition laws and regulations, land acquisition impacts from both a socioeconomic and sociocultural perspective would not be considered significant. Should condemnation be necessary as a last resort, while the landowner would be made economically whole by payment of fair market value, such an occurrence could represent an adverse sociocultural impact for that individual landowner. Such instances are expected to be extremely rare or nonexistent during implementation of this proposed action, and collectively would not represent a significant impact.

Socioeconomic and Sociocultural Impacts

Potential impacts associated with land acquisition could affect individual property owners, occupants, the surrounding community, and GovGuam. Economic impacts presented in this section are total impacts which include impacts that would be generated by the proposed action both directly and indirectly. Individual owners and occupants might be impacted from an economic perspective or a sociocultural perspective. Economic impacts associated with land acquisition are those that are purely financial. Sociocultural impacts associated with land acquisition are less tangible and are based on conceptual frameworks such as social disarticulation and cultural marginalization (the deterioration of social structures, networks, or belief systems), and social and psychological marginalization, stress, and anxiety (a person’s loss of confidence in society and themselves, feelings of injustice, and reduced social status). See Appendix D, Section 5.2.2 for more detail.
Individual Owners/Occupants

With regard to economic impacts, if acquisition of privately-owned lots were to occur through negotiated purchase with the owners, there would be no adverse impact. As required under the Uniform Act, the purchase would take place at fair market value. Conversely, if the property was acquired through condemnation the federal government would still be required under the Uniform Act to reimburse the property owner at the fair market value. Therefore, the land acquisition would not cause an adverse economic impact to individual landowners.

With regard to sociocultural impacts, this alternative would require the acquisition of 19 separate lots, including one lot owned by GovGuam. Of the lots required, 17 are known to be privately owned and one lot has unknown ownership, so up to 18 different private parties could be affected. It is anticipated that, in all cases, a negotiated sale or lease between the federal government and a willing seller would be arranged, and there would be no adverse sociocultural impact. In the unlikely event that the land were acquired through condemnation, it is possible that the individual landowner would potentially consider the forced sale or lease of property to be an adverse direct, long-term impact (despite being paid fair market value).

Community

With regard to economic impacts, the NAVMAG (East/West) lands are either undeveloped in a natural state or represent conservation lands (see Table 5.2.15-2), and no current agricultural activities or other economically productive land uses were identified. Because the land that would be acquired does not currently have an economically productive use, and the fair market value would account for the highest and best use, there would be no adverse economic impact.

With regard to sociocultural impacts, the addition of an estimated 1,894 acres (766 ha) of federal land on Guam would be considered by some citizens to be an adverse impact due to the current extent of federal land that is under DoD custody and control (approximately 26% of all land on Guam, as shown in Section 5.1.15), which would increase to 27.3% with acquisition of the NAVMAG East/West parcel. However, because of the DON’s commitment to the concept of “net negative,” by the end of the Marine Corps relocation there would be no net increase in federal land under the custody and control of the DoD.

Five recreational sites are located in the vicinity of Alternative 2 (see Section 5.2.7). Four of the five recreational sites are located on NAVMAG and are only open to installation personnel and their guests. The remaining recreational site, Talofofo Falls Park and Hiking Trail, is accessible to the public along the existing access road between Route 4 and the Dandan Communication Site and is not located within the land acquisition boundary. Although access to Talofofo Falls Park and Hiking Trail may be temporarily affected during construction activities along the access road, the proposed construction activities along the access road would be short-term in duration and associated direct sociocultural impacts would be less than significant.

Government of Guam

The current 1,498 acres (606 ha) of land in the NAVMAG (East/West) parcel that are privately owned are subject to GovGuam property tax. The average per acre value for these parcels is $206,911. The total tax base for private lands is estimated to be $310 million ($206,911 x 1,498 acres). On this property, land owners pay an estimated $263,500 in property taxes to GovGuam. Acquisition of this property by the federal government would represent a loss of 1.3% of FY 2011 GovGuam property tax revenues, representing an adverse but less than significant impact.
GovGuam owns 360 acres (146 ha) of the land subject to acquisition under this alternative. At present, this land is not developed, leased or otherwise generating income for GovGuam. As such, either a sale or lease would generate a small beneficial direct economic effect (though less than significant in magnitude).

5.2.16 Hazardous Materials and Waste

5.2.16.1 Affected Environment

The current DoD ROI on Guam for hazardous materials and waste in this section includes DON property and GovGuam lands proposed for development of a LFTRC. The DON property includes the southern portion of the NAVMAG site and GovGuam lands include undeveloped lands east of the southern portion of the NAVMAG site, undeveloped areas between Dandan Communication Station and the proposed LFTRC site, as well the southern and western perimeter of the proposed training range SDZs.

Hazardous Material and Hazardous Waste Management

The affected environment or present conditions at NAVMAG with regards to hazardous materials and hazardous waste management would be the same as described in Section 3.16.1 of this SEIS, which provides a summary of hazardous materials, hazardous waste, toxic substances, and contaminated site information pertinent to Guam. Currently, there are three hazardous waste accumulation sites (NAWMU-1, B-870, NMC-EAD, B-901 and B-740, Ordnance) and two less-than-90 day storage areas (585B U.S. Navy Lab and B-404) located at NAVMAG (NAVFAc Pacific 2013a).

Contaminated Sites

No IRP sites are located in the vicinity of the portion of NAVMAG proposed for development for an LFTRC under Alternative 2 (Figure 5.2.16-1).

Military Munitions Response Program

No MMRP sites were identified in the vicinity of the area of NAVMAG proposed for development under Alternative 2.

Toxic Substances Management

Currently, the area of NAVMAG that would be affected by the proposed LFTRC is undeveloped and does not contain any structures. Therefore, LBP, ACM and PCBs would not be present.

According to USEPA, the parcel is located in an area classified as Zone 3 for Radon, indicating average indoor radon levels of less than 2 pCi/L.

5.2.16.2 Environmental Consequences

Construction

Hazardous Materials and Waste

Construction would result in a short-term increase in the use of hazardous materials and generation of hazardous waste that would cease at the completion of construction activity and would be the same as described in Section 5.1.16.2 of this SEIS. Should there be a need to import off-island earthen materials, all GEPA, Department of Agriculture, and local rules regulations would be followed.

Due to the short-term nature of the construction activity and the limited amount of hazardous materials and waste that would be used and generated, direct or indirect impacts would be less than significant.

- Land Acquisition Area
- Surface Danger Zone (SDZ)
- MMRP Sites

Source: NAVFAC Pacific 2013
Contaminated Sites

No contaminated sites are known to be present in the proposed LFTRC area. Therefore, construction activities under Alternative 2 would have no direct or indirect impacts on contaminated sites.

Toxic Substances

Construction activities associated with Alternative 2 would have no direct or indirect adverse impacts on toxic substances. There are no structures in the proposed project area and these substances would not be used to construct proposed new facilities on Guam. Because the proposed construction areas are located in a USEPA Radon Zone 3, it is unlikely that new buildings, facilities and structures would encounter radon intrusion. Therefore, no direct or indirect impacts would occur during construction or operations.

Operation

Hazardous Materials

Live-fire training ranges would generate a long-term increase in the release of hazardous materials from expended training materials resulting from proposed new training operations, and associated impacts would be similar to those described in Section 5.1.16.2 of this SEIS; however, because the training ranges and associated SDZs would be land-based, there would be no direct impacts to open waters. As described in Section 5.1.16.2, direct or indirect impacts would be less than significant.

Hazardous Waste

Operation of the live-fire training ranges would result in a long-term increase in the generation of hazardous waste and would be the same as described in Section 5.1.16.2 of this SEIS. As described in Section 5.1.16.2, direct or indirect impacts would be less than significant.

Contaminated Sites

No contaminated sites are known to be present in the proposed LFTRC area. Therefore, Alternative 2 would have no direct or indirect impacts on contaminated sites.

Toxic Substances

Long-term operational activities associated with Alternative 2 would have no direct or indirect adverse impacts on toxic substances. These substances would not be generated by site operations. Because the proposed Alternative 2 is located in a USEPA Radon Zone 3, it is unlikely that new buildings, facilities and structures would encounter radon intrusion. Therefore, no direct or indirect impacts would occur during construction or operations.

5.2.17 Public Health and Safety

5.2.17.1 Affected Environment

Operational Safety

Currently, no vehicle access exists to the area proposed as Alternative 2. To protect the general public from intentional or accidental entry onto the NAVMAG property, locked or manned gates are used where vehicle access is provided, and a series of warning signs cautioning unauthorized personnel not to enter the area are posted along the perimeter of the installation. Unauthorized personnel are not allowed on the installation at any time.

A small arms range and sniper range are present on the west-central portion of NAVMAG. In addition, an emergency demolition range is in the central portion of NAVMAG, west of the Fena Valley Reservoir.
Both of these ranges are not within the Alternative 2 development area. Activities at these ranges are conducted in accordance with SOPs to ensure the safety of range participants and the general public.

The munitions operations and storage area as well as the emergency demolition range on NAVMAG have associated ESQD arcs that restrict the construction of inhabited buildings and other non-munitions related activities, to minimize potential impacts on personnel and the general public from an explosive mishap. Explosives handling and storage is the primary function within the munitions storage area. Detonation of UXO in emergency situations is the primary function of the emergency demolition range.

**Environmental Health Effects**

**Noise**

Aviation training is limited to four helicopter landing zones on NAVMAG. Landing Zones 2 and 4 are within proposed SDZs associated with Alternative 2 development. The overflight of helicopters produces noise. However, this training is infrequent and occurs at locations within the installation away from populated areas, resulting in no community noise effect. In addition, a small arms range and sniper range are internal to the installation and do not present a noise management issue.

Land demolition activities take place at the NAVMAG demolition range in the central portion of the installation, approximately 4,100 feet (1,250 m) from the closest public boundary. Although individuals exposed to these events may be startled if they are unaware of the source of the noise, the brevity and relative infrequency of activities does not result in noise contours extending onto adjacent public lands. Details regarding current noise conditions at NAVMAG are provided in Section 5.2.4.1.

**Water Quality**

The Fena Valley Reservoir, which is the primary drinking water source for the southern portion of Guam, is within the NAVMAG boundary. Water quality from the Fena Valley Reservoir and regional springs is generally high, requiring minimum treatment and chlorination for domestic use. Threats to water quality include sedimentation from accelerated erosion, eutrophication caused by persistent conditions of low dissolved oxygen, and fecal material contamination from animals (DON 2010a). Section 5.2.2.1 provides details regarding current quality of potable water sources.

**Hazardous Substances**

Current management practices and contingency plans for the use, handling, storage, transportation, and disposition of hazardous substances associated with NAVMAG ensure that exposure to the environment and human contact is minimized.

The IRP focuses on cleaning up releases of hazardous substances that pose risks to the general public and/or the environment. The MMRP focuses on identifying and removing MEC. No IRP or MMRP sites are situated within the Alternative 2 development area.

**Unexploded Ordnance**

The presence of UXO within the Alternative 2 area is unknown. However, Guam was an active battlefield during WWII. As a result of the occupation by Japanese forces and the subsequent assault by Allied/American forces to retake the island, unexploded military munitions may still remain.

**Traffic Incidents**

No high crash frequency locations have been identified in the vicinity of the Alternative 2 area.
5.2.17.2 Environmental Consequences

Potential impacts on public health and safety from implementation of Alternative 2 would be similar to those discussed for Alternative 1 (see Section 5.1.17).

Operational Safety

Construction Safety

Potential impacts from construction safety would be similar to those discussed for Alternative 1. During construction activities, a health and safety program would be implemented by the construction contractors based on industry standards for accident and pollutant release prevention. Because a health and safety program would be implemented for construction activities, and the general public would be excluded from entering construction areas, potential short-term construction impacts on public health and safety would not result in any greater safety risk. Therefore, no direct or indirect impact on public health and safety related to construction activities is anticipated.

Operation/Range Safety

To protect the general public from intentional or accidental entry onto live-fire training ranges, a series of warning signs cautioning unauthorized personnel not to enter the area would be posted along the perimeter of the installation as well as at the range area. Unauthorized personnel would not be allowed on the installation or range at any time.

SOPs require that before conducting training activities, the general public and non-participating personnel would be cleared from the area so that the only public health and safety issue would be if a training event exceeded the safety area boundaries. Risks to public health and safety would be reduced by confirming that the training area is clear. The Range Safety Officer would ensure that hazardous areas are clear of personnel during training activities. After a live-fire event, the participating unit would ensure that weapons are safe and clear of live rounds.

Use of established training areas and compliance with appropriate range safety procedures would reduce the potential for interaction between the general public and personnel that are training. Specific and documented procedures would be in place to ensure the general public is not endangered by training activities. Therefore, Alternative 2 would result in no direct or indirect impact on public health and safety from operations and training activities.

Explosive Safety

For Alternative 2, SDZs have been defined for each of the ranges in the proposed LFTRC, to identify the areas requiring control of unauthorized access to live-fire training operations. The SDZs established for Alternative 2 reflect a “worst case scenario” for weapons use to ensure the safety of on- and off-range personnel and civilians. The proposed layout of the SDZs is provided in Chapter 2. With implementation of appropriate range safety procedures, no direct or indirect impact on public health and safety is anticipated from Alternative 2 activities.

The current munitions operations and storage area, as well as the emergency demolition range on NAVMAG, have associated ESQD arcs that restrict the construction of inhabited buildings and other non-munitions related activities to minimize potential impacts on personnel and the general public from an explosive mishap. The ESQD arcs overlap with SDZs associated with proposed live-fire training positions. Because the ESQD arcs do not overlay proposed live-fire training firing positions (only SDZs),
no conflict between the current munitions storage and EOD range activities with the proposed live-fire training activities would occur.

Although the SDZs for Alternative 2 activities do not encumber the existing breacher house, sniper range, or EOD range, they do encumber Landing Zones 2 and 4, and a portion of the non-firing maneuver area. Use of these areas would be prohibited when Alternative 2 is supporting live-fire training.

Ordnance used at Alternative 2 would be handled, stored, and transported in accordance with Marine Corps explosive safety directives (MCO P8020.10A, Marine Corps Ammunition Management and Explosives Safety Policy Manual), and munitions handling would be carried out by trained, qualified personnel. Therefore, no direct or indirect impacts related to explosive safety are anticipated.

Environmental Health Effects

Noise

Potential impacts on public health and safety under Alternative 2 noise would be similar to those discussed for Alternative 1. Increases in noise emissions associated with implementation of the short-term construction phase of this alternative with identified BMPs would be less than significant. Enforcement of OSHA guidelines for hearing protection for workers would be the responsibility of the construction contractors. Noise from Alternative 2 activities (i.e., weapons firing) would be heard on adjacent lands from the range. However, no residential land is near Alternative 2 and no people would be exposed to incompatible noise levels (see Section 5.2.4.2). The sound generated from Alternative 2 activities would be intermittent (only when training activities occur) and short term. Based on the modeled noise for Alternative 2 activities (see Section 5.2.4), the direct or indirect impact associated with noise on public health and safety would be less than significant.

Water Quality

Potential impacts on public health and safety from water quality concerns would be similar to those discussed for Alternative 1. Water withdrawal would likely increase. However, sustainability practices would be implemented to reduce the amount of water needed (see Section 5.2.2.2). The resulting total annual water withdrawal would be less than the sustainable yield, and monitoring of water chemistry would identify any emerging issues to ensure no harm to the water supply.

The Fena Valley Reservoir is within the NAVMAG boundary and is the primary drinking water source for the southern portion of Guam. The reservoir is located northwest of Alternative 2 and is outside established SDZs for live-fire training activities. The SDZs define the ground area needed to contain projectiles, fragments, debris, and components resulting from the firing, launching, and/or detonation of weapons. Because Alternative 2 activities would be contained within the designated SDZs, no direct or indirect impact on the Fena Valley Reservoir is anticipated.

Because measures would be taken to maintain a sustainable water supply and the Fena Valley Reservoir is outside the SDZs for Alternative 2 activities, public health and safety impacts from long-term increased demand on potable water and potential water-related illnesses would be less than significant.

Hazardous Substances

Potential safety impacts from use of hazardous substances would be similar to those discussed for Alternative 1. Implementation of this alternative would result in an increase in the use, handling, storage, transportation, and disposition of hazardous substances. These activities would be conducted in accordance with applicable hazardous material and waste regulations, and established BMPs and SOPs to
ensure the health and safety of workers and the general public is maintained. IRP and MMRP investigations and/or remediation activities on NAVMAG would continue in an effort to clean up past releases of hazardous substances that pose a risk to the general public and the environment, and receive regulator concurrence that necessary actions have been completed to ensure the safety of the general public. Because hazardous substance management and IRP/MMRP investigative/cleanup activities would be conducted in accordance with applicable regulations and established BMPs and SOPs, no direct or indirect impact on public health and safety is anticipated.

With regard to exposure to airborne toxic dust related to live-fire training activities and range maintenance, lead is the primary contaminant of concern. Very small lead particles can become airborne if wind, foot traffic, or maintenance activities disturb lead-contaminated soil. Firing ranges would be designed and constructed so that participating personnel are not exposed to airborne contaminants above permissible limits. The nearest residential population is located approximately 0.5 mile (0.8 km) to the north and emissions migrating off range would likely be much lower than on-site. Analysis of firing range emissions presented in the 2010 Final EIS (Volume 2, Chapter 5: Air Quality, Section 5.2.7: Summary of Impacts, Table 5.2-8, page 5-36) indicated that operations emissions from firing range components would be well below significance criteria. Because range maintenance procedures ensure that participating personnel are not exposed to airborne contaminants above permissible limits and analysis of firing range emissions are below significance criteria, a less than significant direct or indirect impact on public health and safety from firing range activities is anticipated.

Unexploded Ordnance

Potential impacts from UXO would be similar to those discussed for Alternative 1. Excavation for building foundations, roads, underground utilities, and other infrastructure could encounter unexploded military munitions in the form of UXO, DMM, and/or MPPEH. Exposure to MEC could result in death or injury to workers. With the exception of public access provisions outlined through the 2011 PA process (see Section 4.4.10, Cultural Resources), the general public would be excluded from entering construction zones and training areas. To reduce the potential hazards related to the exposure to MEC, ESS documentation would be prepared to outline specific measures that would be implemented to ensure the safety of workers and the general public. BMPs that would be implemented would include having qualified UXO personnel perform surveys to identify and remove potential MEC items before beginning ground-disturbing activities. Additional safety precautions would include having UXO personnel supervision during earth-moving activities and providing MEC awareness training to construction personnel involved in grading and excavations before and during ground-disturbing activities. Because UXO would be identified and removed before beginning construction activities and construction personnel would be trained about the hazards associated with unexploded military munitions, potential direct or indirect impacts from encounters with UXO would be minimized and would be less than significant.

Traffic Incidents

The potential for long-term increased traffic incidents is small (5% increase [see Section 4.1.17.2]). Because no high crash frequency intersections are located near NAVMAG and the overall potential long-term increase in the number of traffic accidents as a result of the increase in personnel would be minimal, a less than significant impact is anticipated on the health and safety of the citizens of Guam from traffic incidents.
5.2.18 Environmental Justice and the Protection of Children

5.2.18.1 Affected Environment

The affected environment under the NAVMAG (East/West) alternative is considered to be the entire island of Guam, as discussed in Section 4.1.18.1 of this SEIS. The proposed action under Alternative 2 would be located in the southern region of Guam, as defined in Section 4.1.18.1. The villages of Santa Rita, Agat, Umatac, Talofofo, and Yona are within this region.

5.2.18.2 Environmental Consequences

Potential impacts to environmental justice populations under Alternative 2 would be to noise, recreation, land acquisition, and public health and safety. The impact analysis discussion provided in the following sections is focused primarily on operational impacts of implementing the proposed LFTRC Alternative 2, as LFTRC construction impacts as related to environmental justice would be minimal and short-term, with no measurable effect on Guam’s special-status populations.

Noise

There would be no impact due to construction noise under Alternative 2 because construction activities would be in an unpopulated area of Guam. Construction areas would be at least 1 mile (1.6 km) away from the nearest receptors.

There would be no direct impacts due to live-fire training noise under this alternative because there would be no populated residential areas affected and none of the noise significance criteria stated in the Marine Corps Guidance memo for land use and noise exposure would be exceeded, as described in Section 5.2.4. Noise. There would be no indirect impacts because no population is affected and none of the significance criteria would be exceeded.

Recreation

There are several recreational resources in the area, as described in Section 5.2.7. Potentially-affected resources include Talofofo Falls Park and Talofofo Hiking Trail.

Construction and/or improvement to access roads on non-federal property would be required to reach the proposed ranges in this alternative. The construction impacts would be temporary in nature and would mostly be limited to slow construction and earth-moving equipment slowing access to recreational resources.

There are potential indirect impacts from firing range noise, which could lessen visitor enjoyment of publicly-accessible recreational resources in the area of the LFTRC. However, the impacts from Alternative 2 are less than significant due to the lack of existing recreational resources in the areas to be potentially acquired.

Tier 1: Are there any minority, low-income, or children populations that would be impacted?

Yes, the recreational resources in this area are generally used by all people of Guam, which includes a high proportion of racial or ethnic minorities, low-income individuals, and children.

Tier 2: Are the applicable disadvantaged groups disproportionately affected by the negative environmental consequences of the proposed action(s)?

No, minority and low-income populations and children are not disproportionately affected by the increase in demand to recreation areas, because the entire region has a minority or special status population. All people of Guam would be affected by impacts to recreational resources. Therefore, Alternative 2 would
not result in disproportionately high and adverse effects on minority or low-income populations nor would there be disproportionate risks to the health and safety of children.

**Land Acquisition**

There would be both beneficial and adverse direct and long-term impacts on adjacent and nearby land uses from the proposed access road/utility easements, as discussed in Section 5.2.6.2, Land and Submerged Land Use. In addition, there would be short and long-term direct and indirect significant adverse impacts to land ownership if there is an unsolicited sale of privately-owned land to the federal government for the proposed Alternative 2. Although there may be landowners who are interested in selling their land, land ownership impacts are considered significant until negotiations have been completed. There would also be other relocation activity and land acquisition, or long-term leases for roadway improvements, to implement this alternative.

*Tier 1: Are there any minority, low-income, or children populations that would be impacted?*

Yes, based on the data provided in Section 4.1.18-1, private landowners are likely to be racial minorities that live in areas with a higher poverty rate than the U.S.

*Tier 2: Are the applicable disadvantaged groups disproportionately affected by the negative environmental consequences of the proposed action(s)?*

No, because all of Guam is considered a racial and ethnic minority population, minorities would not experience disproportionately high and adverse effects due to land acquisition. Because federal regulations regarding land acquisition would ensure that significant economic impacts to landowners and occupants do not occur, low-income populations would not experience disproportionately high and adverse effects due to land acquisition. Land acquisition would not result in health and safety risks that would disproportionately impact children. Therefore, Alternative 2 would not result in disproportionate land use or socioeconomic impacts to minority and low-income populations or children as a result of land acquisition.

**Public Health and Safety**

No impacts to public safety are anticipated from operational safety concerns (i.e., explosive safety, electromagnetic safety, and construction safety). No impacts to public health and safety are anticipated from management of hazardous substances. Less than significant impacts are anticipated to public health and safety from firing range air emissions. Less than significant impacts are anticipated from construction and operational noise, water quality, and UXO.

*Tier 1: Are there any minority, low-income, or children populations that would be impacted?*

Yes, the populations of the villages affected by Alternative 2 have high percentages of racial minorities, low-income groups, and children.

*Tier 2: Are the applicable disadvantaged groups disproportionately affected by the negative environmental consequences of the proposed action(s)?*

No, impacts would not be disproportionate because regardless of where the LFTRC is located on Guam, high (relative to the U.S.) percentages of minorities, low-income residents, and children would be affected. As LFTRC alternatives may only occur on Guam (by international treaty), and all of Guam is considered to have a high proportion of minorities, low-income residents, and children, impacts cannot be considered disproportionate.
5.3 NAVAL MAGAZINE (NORTH/SOUTH) LIVE-FIRE TRAINING RANGE COMPLEX - ALTERNATIVE 3

Under Alternative 3, the proposed development of a live-fire training range complex would occur at NAVMAG North/South. Details about this alternative are provided in Section 2.5.4.3 and the proposed site is illustrated in Figure 2.5-4.

5.3.1 Geological and Soil Resources

5.3.1.1 Affected Environment

The affected environment for the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.1.1 of this SEIS.

The affected environment for geological and soil resources associated with Alternative 3 is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 3: Geological and Soil Resources, Section 3.1.5 South, pages 3-26 to 3-28), which is summarized below for reference. The proposed reduction in the number of relocating Marines and dependents under the 2012 Roadmap Adjustments does not alter the description of the affected environment for geological and soil resources, but it would reduce some potential impacts to geological and soil resources that were determined to be less than significant or mitigated to less than significant in the 2010 Final EIS, as described in the analysis of environmental consequences for Alternative 3 below.

Alternative 3 would be located in the same mountainous area in south-central Guam as Alternative 2. Elevations within the Alternative 3 footprint range from approximately 200 feet (61 m) above MSL in the southeast near the Magazine Relocation Area to approximately 700 feet (213 m) MSL at the MPMG Range in the northwest. Fena Valley Reservoir lies southeast of the Alternative 3 footprint, just beyond the Magazine Relocation Area.

The portion of the Alternative 3 footprint where the ranges would be constructed is underlain primarily by old (Barrigada) limestone, the geologic setting for sinkholes (see Section 3.1.1.1). Based on available topographic and field data, four features have been preliminarily identified as sinkholes/depressions that may contain sinkholes within, or on the perimeter of, the proposed Alternative 3 footprint (Figure 5.3.1-1). The Magazine Relocation Area footprint is underlain by bedrock of volcanic origin. One bedrock fault crosses the proposed MPMG Range, and multiple faults are mapped in the nearby area surrounding the proposed Alternative 3 footprint.

The two dominant soil groups underlying Alternative 3 are the Ritidian-Rock Outcrop Complex and Akina silty clay (Figure 5.3.1-2). Soils within the footprint occur on undulating level to very steep slopes (Young 1988). For the Ritidian-Rock Outcrop Complex soil, runoff is very slow and the water erosion hazard is slight. For Akina silty clay, runoff is rapid and the water erosion hazard is severe (Young 1988). Urban Land Complex soils comprise the remainder of the proposed Alternative 3 footprint. For these soils, the water erosion hazard is low. Prime farmland soils, as defined by the USDA, are soils best suited to producing food, seed, forage, fiber and oilseed crops, favorable for economic production and sustained high yield, with minimal inputs of energy and resulting in least damage to the environment (Young 1988). None of the soils in the Alternative 3 footprint are suitable for agricultural purposes or are identified by the USDA as prime farmland (Young 1988).

With respect to geologic hazards (see Section 3.1.1.1), most conditions at the proposed Alternative 3 location are similar to those at Alternative 2 (i.e., consolidated bedrock underlying the site is not vulnerable to liquefaction, and the site elevation is higher than the maximum recorded tsunami wave run-up). However, unlike Alternative 2, the landslide potential for Alternative 3 is moderate. The limestone bedrock in the area of the Alternative 3 firing ranges presents a potential hazard of surface instability and collapse due to sinkholes. The Magazine Relocation Area would be located on volcanic bedrock, in which sinkholes typically do not form.

5.3.1.2 Environmental Consequences

Potential geology and soil impacts addressed in this section are limited to elements of the proposed action that could affect onshore landforms or that could be affected by geologic hazards. Potential soil contamination issues are addressed in Section 5.3.16.2 of this SEIS (Hazardous Materials and Waste).

Construction

Construction impacts associated with the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.1.2 of this SEIS.

Construction of the new ranges, range support building, roads, bridges, estimated 72 new concrete munitions magazines and related infrastructure associated with Alternative 3 would include clearing, grubbing and grading, and excavation (cut) and filling, and stream rerouting. Earthwork would include 4,932,976 yd$^3$ (3,771,530 m$^3$) of excavation (cut) and 3,130,058 yd$^3$ (2,393,100 m$^3$) of fill resulting in a net 1,802,919 yd$^3$ (1,378,430 m$^3$) of cut (DON 2013a). There are major differences in elevation in the areas planned for construction of the MPMG, KD Rifle, and MRF ranges. There would be substantial changes to surface elevation for construction of the MPMG, KD Rifle and MRF ranges (DON 2103b). Overall, Alternative 3 would involve the largest volume of excavation to construct of any of the action alternatives. Because of the major elevation changes, the substantial alteration of the surrounding landscape, and the amount of excavation, filling and contouring that would occur, Alternative 3 is expected to have a significant direct, long-term impact on topography. Potential mitigation is not considered feasible for this impact because smaller cut/fill volumes would not provide the necessary level surfaces for the referenced ranges. This significant impact to topography would occur with implementation of any LFTRC alternative except Alternative 2, which would involve the least amount of cut and fill (i.e., the impact would be the same for all alternatives except Alternative 2).

Construction of the HG Range would involve 8,894 yd$^3$ (6,800 m$^3$) of cut and 12,641 yd$^3$ (9,665 m$^3$) of fill, for a net of 3,747 yd$^3$ (2,865 m$^3$) of fill. The 1,802,919 yd$^3$ (1,378,430 m$^3$) of net cut generated by construction of the other Alternative 3 ranges would provide sufficient additional fill to supply the need at the HG Range.

The differences in elevation in the areas planned for construction of the MPMG, KD Rifle, and MRF ranges at Alternative 3 are substantially greater than the natural elevation differences in the Alternative 2 footprint. For example, to construct the MPMG Range at Alternative 2, a 30-feet (10-m) high slope would be leveled with about 942,500 yd$^3$ and (725,000 m$^3$) of cut and 910,000 yd$^3$ (700,000 m$^3$) of fill. To construct the same range at Alternative 3, a 75-to-100 feet (22 to 30 m) high slope would be leveled with 2.47 million yd$^3$ (1.9 million m$^3$) of fill. Due to the steeper topography in the Alternative 3 footprint, nearly 4 times as much excavation and 2.5 times as much fill overall would be needed to level the ranges for Alternative 3 as for Alternative 2. There is a potential for increased erosion, compaction, and soil loss from physical disturbance caused by construction activity and changes to existing topography. However, project design and construction would incorporate engineering controls as BMPs to minimize erosion.
within the project construction footprint, as required by Title 22 of GAR, Chapter 10 Guam Soil Erosion and Sediment Control Regulations. Examples of such engineering controls are described in Section 5.2.1.2 of this SEIS.

In addition, construction activities associated with Alternative 3 would comply with the Construction General Permit. Potential construction-specific stormwater BMPs would be implemented in compliance with the Construction General Permit as listed in Section 4.1.2.2. Construction-specific stormwater BMPs would provide erosion and sediment control during the construction period, generally by employing on-site measures that reduce the flow of stormwater and minimize the transport of soils and sediment off-site. Fill material would be generated on-site, whenever possible. In addition, roadway-specific BMPs, as identified in the most recent CNMI and Guam Stormwater Management Manual, would be included in the planning, design, and construction of all roadways and facilities. Through compliance with 22 GAR Chapter 10 and the Construction General Permit and implementation of roadway stormwater BMPs, and because the rate of erosion and soil loss would not be substantially increased, direct, short-term impacts to soils from erosion during construction of Alternative 3 would be less than significant. In addition, no indirect, short-term impacts associated with soil erosion are expected.

The soils in the Alternative 3 footprint are not identified as prime farmland, and no existing agricultural use is identified for the area of disturbance (it is DoD property included within NAVMAG and the land is used for military purposes). Therefore, disturbance of soil during construction of Alternative 3 would have no direct or indirect short-term impacts to agricultural soils.

There are four topographic features that may contain sinkholes within, or on the perimeter of, the Alternative 3 footprint (see Figure 5.3.1.1). For any sinkholes discovered before or during construction, BMPs would include compliance with 22 GAR Chapter 10 § 10106F. In order to ensure compliance with 22 GAR Chapter 10 § 10106F, BMPs would be modified or an environmental and hydrogeologic assessment must be performed to ensure adverse effects will not result, including but not limited to the displacement of groundwater, interference with well production, significant changes to groundwater recharge, flooding, or the threat or introduction of any pollutant to groundwater. After a preferred alternative is selected and the ROD is signed for the proposed project, final design work would begin for the preferred alternative site. A geotechnical study, including subsurface borings, would be conducted to determine whether the depressions on the site contain sinkholes, and whether there are additional sinkholes not evident from the surface. Hydrogeological studies would be conducted to confirm groundwater flow at the site as well. The geotechnical and hydrogeological studies would be coordinated with the GEPA to design and implement an appropriate analysis. These studies would be part of the final design process and would take place before any construction begins. With implementation of these BMPs, and because no sinkholes would be filled that would adversely affect site drainage, no adverse impacts to sinkholes would occur. Therefore, construction of Alternative 3 would have less than significant direct, short-term impacts to sinkholes.

Hazards associated with earthquakes, fault rupture and slope instability would be minimized by adherence to UFC 3-310-04 Seismic Design of Buildings dated June 1, 2013 (USACE 2013). The Alternative 3 site is located inland and above the elevation prone to tsunamis, and so would not be susceptible to inundation. The consolidated limestone and volcanic bedrock underlying the site is not vulnerable to liquefaction. In addition, there would not be a change to soil and/or bedrock conditions that would increase vulnerability to a geologic hazard. As stated in the previous paragraph, 22 GAR Chapter 10 § 10106F requires that for sinkholes within the project development footprint that would be modified or used, an environmental and hydrogeologic assessment must be performed to ensure adverse effects will
not result. Compliance with these regulations would minimize potential geologic hazards associated with sinkholes. Therefore, construction of Alternative 3 would have less than significant direct and indirect short-term impacts with respect to geologic hazards.

Operation

Operational impacts associated with the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.1.2 of this SEIS.

Alternative 3 operations would not alter topography post construction, so no direct or indirect impacts to topography would occur.

The firing range activities and conditions and conditions that may directly cause or increase naturally occurring soil erosion during the operational phase would be the same as those described for Alternative 2 and are described in Section 5.2.1.2 of this SEIS. Similar to Alternative 2, under Alternative 3 the significant changes to topography during construction of the MPMG, KD Rifle, and MRF ranges could alter natural surface flow patterns that could increase soil erosion. Munitions storage in the relocated magazines would not involve any surface disturbance.

The area of impervious surfaces that would be constructed for the ranges and associated infrastructure (range buildings, roads, and parking areas) would comprise approximately 21.0 acres (8.5 ha) (Appendix F) including about 20.1 acres (8.1 ha) for Alternative 3 and about 0.9 acre (0.4 ha) for the HG Range. There would be a minor increase in runoff from the new impervious surface area as compared with existing conditions. Stormwater infrastructure improvements included as part of the proposed action would incorporate LID measures and BMPs to minimize soil erosion from this increased runoff. Where possible, stormwater flow paths would continue to mimic pre-development flows through area topography. Stormwater BMPs that would be implemented to minimize and control runoff would also minimize soil erosion.

The range complex would be managed in accordance with current Marine Corps range management policies and procedures, which are designed to ensure the safe, efficient, effective, and environmentally sustainable use of the range area. A thorough explanation of Marine Corps range management is detailed in the 2010 Final EIS (Volume 2, Chapter 2: Description of Proposed Action and Alternatives, Section 2.3.1.4: Firing General Military Skills, pages 2-55 to 2-59). Marine Corps range management policies and procedures include procedures for removing expended rounds from live-fire ranges with impact berms every 5 years, managing stormwater, controlling erosion, maintaining vegetation on berms and drainage ways and turf on the range, and restricting vehicular activities to designated/previously identified areas. Range roads would be maintained to minimize erosion.

There would be minor ground disturbance associated with utility maintenance. Construction stormwater BMPs would be implemented during maintenance activities to minimize and control runoff on-site and minimize potential effects of soil erosion.

There are no agriculturally productive soils or existing agricultural uses in the area of the proposed Alternative 3, so no direct or indirect long-term impact to agricultural soils would occur due to Alternative 3 operations.

A potential indirect impact of firing range operations includes the possibility of live ammunition causing wildland fires. As a BMP and in accordance with range safety protocols, a Range Fire Management Plan would be prepared, based on the DON’s Wildland Fire Management Plan (USFS 2008). It would include protocols for monitoring fire conditions and adjusting training as needed. Units undergoing training at the
ranges would be briefed by range control on requirements suitable to the conditions of the day and protocols should a fire occur (e.g., specifying how the range would shut down and how fire suppression action would be taken). The existing *Wildland Fire Management Plan* (USFS 2008) that covers NAVMAG would be extended to cover bordering non-federal lands that could spread fire onto the ranges and would continue to be implemented under Alternative 3. With these measures, potential wildfires caused by the live ammunition would be unlikely. Effects to soils from erosion associated with wildfires associated with operation of Alternative 3 would be minimal and direct and indirect impacts would be less than significant.

With implementation of Marine Corps range management policies and procedures, fire suppression and potential mitigation measures, and stormwater BMPs (for ranges and ground-disturbing maintenance) less than significant direct and indirect long-term impacts to soils from erosion would occur due to Alternative 3 operations.

The BMPs for sinkholes would be implemented in the event that maintenance activities should involve sinkholes or their immediate perimeter, so there would be no adverse impacts. Therefore, Alternative 3 operations would have less than significant direct, long-term impacts to sinkholes.

Hazards associated with earthquakes, fault rupture and slope instability would be minimized by adherence to UFC 3-310-04 Seismic Design of Buildings dated June 1, 2013 (USACE 2013) during project design and construction, so direct and indirect long-term impacts with respect to seismic hazards would be less than significant. The consolidated limestone and volcanic bedrock underlying the site is not vulnerable to liquefaction. Alternative 3 is located inland and higher than the elevation prone to tsunamis, so it would not be susceptible to inundation. In addition, there would not be a change to soil and/or bedrock conditions that would increase vulnerability to a geologic hazard. Implementation of sinkhole BMPs would minimize potential geologic hazards associated with sinkholes. Therefore, Alternative 3 operations would result in less than significant direct and indirect long-term impacts associated with geologic hazards.

### 5.3.2 Water Resources

#### 5.3.2.1 Affected Environment

The affected environment for water resources in the Alternative 3 NAVMAG ranges is described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.1.5.1: Naval Munitions Site, pages 4-68 to 4-71). A summary of site conditions for Alternative 3 is provided in Appendix F. The affected environment for the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.2.1 of this SEIS.

**Surface Water**

As indicated in the 2010 Final EIS, numerous rivers are located within the NAVMAG portion of the project area. The non-DoD portion of the project area is located along the headwaters of Agat, Taelayag, and Central Talofofo watersheds, but does not contain any surface waters (Figure 5.3.2-1).

Specifically, the proposed construction areas and SDZ for the Alternative 3 ranges are spatially located along the Talisay and Bonya river systems of the Northern Talofofo Watershed and the Maulap, Almagosa, and Sadog Gago river systems of the Central Talofofo Watershed (note: referred to as the “Fena Reservoir Watershed” in the above referenced section of the 2010 Final EIS) (NAVFAC Pacific 2013a). The Talisay River includes numerous, unmapped, intermittent tributaries, which often connect the wetland features of the area. In the areas proposed for locating the various range footprints, the Talisay River transitions from a steep and incised channel, exhibiting step pool characteristics, to an undefined, wide, flooded swamp, becoming narrow only where it passes through road culverts. The Bonya River channel in project area is confined by topography and appears to be fairly stable, with few signs of recent bank erosion, and travels through heavily forested terrain. The Fena Valley Reservoir is located within the Central Talofofo Watershed (see Figure 5.3.2-1).

NAVMAG is characterized by dense forest vegetation, a significant road network, and restricted access. These three factors together contribute to a lower risk of arson fires, which affect many of the other upland, savanna-grassland dominated watersheds in Guam (i.e., the non-federal lands in Alternatives 2 and 4) (NAVFAC Pacific 2013a). Presence of a vegetative cover provides soil with natural erosion protection. If this cover is lost, due to a forest fire for example, then the potential for soil erosion increases substantially. The presence of a munitions storage facility within the NAVMAG boundaries and the need to protect property aboard the installation necessitates a few proactive measures such as (1) appropriate structural fire-prevention measures (fire breaks exist in some locations on NAVMAG), (2) effective fire-suppression policies (no smoking or open-air camp fires) are in place and strictly enforced, and (3) the installation can move quickly to respond to accidental fires (NAVFAC Pacific 2013a). There is an existing Wildland Fire Management Plan (USFS 2008) that covers NAVMAG.

The proposed Alternative 3 ranges are generally located on soils with naturally lower soil erosion potential as compared to the Alternatives 2 and 4 range alignments (NAVFAC Pacific 2013a). Also, these areas are covered with dense vegetation, which further reduces the likelihood of soil erosion. Soil disturbances resulting from ungulate (pigs, carabao, and deer) activity appears to be one of the major potential sources of soil erosion in this area. Persistent feeding and grazing creates well-worn trails that do not support vegetation and are therefore susceptible to getting eroded. Grazing activities also strip the understory, which results in loss of natural erosion control. The animals also regularly trample and dig in the soil for roots and tubers, which aggravates soil particle release (NAVFAC Pacific 2013a).

Soil erosion can degrade water quality in rivers and Fena Valley Reservoir and over time can diminish the storage capacity of Fena Valley Reservoir. Overall, the Alternative 3 project area is located primarily on various types of Akina soils, which are characterized by relatively high soil erosion potential and can produce high concentrations of very fine clay suspended sediments (NAVFAC Pacific 2013a).

The FEMA mapped 100-year floodplains are also shown in Figure 5.3.2-1. There are no 500-year floodplains in the project vicinity.

Groundwater

As indicated in the 2010 Final EIS, groundwater is found primarily in the low-permeability volcanic rocks and there is currently no groundwater extraction in the Alternative 3 project area.

Nearshore Waters

As indicated in the 2010 Final EIS, there are no nearshore waters located near the Alternative 3 project area due to its interior location on Guam. However, the Talofofo River discharges into the nearshore waters of Talofofo Bay (see Figure 5.2.2-1).
Wetlands

As indicated in the 2010 Final EIS, there are extensive wetlands in the Alternative 3 project area. Recent on-site wetland confirmation surveys were conducted at NAVMAG in May and November 2012 for this SEIS. The on-site confirmation was a non-jurisdictional wetland delineation (delineation being the establishment of wetland boundaries). A jurisdictional delineation establishes the boundaries of wetlands that are subject to requirements in the CWA and its implementing regulations and requires the approval of the USACE.

The wetlands identified during the 2012 survey are palustrine emergent wetlands with persistent vegetation that are seasonally flooded/saturated (PEM1E); palustrine forested wetlands that are semi-permanently flooded (PFO3F); or palustrine scrub/shrub vegetation that are seasonally flooded/saturated (PSS3E). The 2012 field survey delineated a total of 36.9 acres (15.0 ha) of wetlands in the project area as shown in Table 5.3.2-1 and Figure 5.3.2-1 (NAVFAC Pacific 2013b). This area includes 3.3 acres (1.3 ha) of forested wetlands as mapped by USFS (2006). All of these wetlands are all considered potentially jurisdictional pending a Jurisdictional Determination by the USACE.

For portions of the project area located outside the 2012 field survey, NWI data was used (NWI maps indicate the potential for wetland areas, but are not official determinations). The NWI maps indicate 0.7 acre (0.3 ha) of NWI wetland areas as shown in Table 5.3.2-1 and Figure 5.3.2-1 (USFWS 2010). The NWI wetlands are identified as palustrine scrub/shrub vegetation that are seasonally flooded (PSS1C). The project area outside the 2012 survey area would require a wetland delineation survey and review by the USACE to verify the location and size of any wetlands and whether they are jurisdictional.

5.3.2.2 Environmental Consequences

Construction

General construction impacts to water resources would be similar to those described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.4: South, page 4-112) and under Alternative A in Section 4.1.2.2 of this SEIS. Alternative 3 would occur in an area that contains waters of the U.S. and would be required to comply with the Construction General Permit as described under Alternative A in Section 4.1.2.2 of this SEIS. Construction impacts associated with the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.2.2 of this SEIS.

Under Alternative 3, the proposed LFTRC construction activities at NAVMAG would result in the potential for a short-term increase in stormwater runoff, erosion, and sedimentation. However, through compliance with the Construction General Permit and Program SWPPP and implementation of a site-specific SWPPP and associated erosion control, runoff reduction, and sediment removal BMPs (see Table
4.1.2-2), these effects would be minimized. Specifically, the site-specific SWPPP would identify appropriate BMPs for the site that would serve to contain runoff and sediment on-site by reducing the flowrate of runoff and thereby minimize transport of suspended sediment through settling and promote infiltration of runoff.

**Surface Water**

Surface waters that are potentially affected by the various project footprints are shown in Figure 5.3.2-1. The KD Rifle, MPMG, MRF ranges and the northern portion of the Non-standard Small Arms Range would drain to the Talisay River. The remaining portion of the Non-standard Small Arms Range and the KD Pistol Range would drain to the Bonya River (NAVFAC Pacific 2013a). The range road would cross the Talisay River. The Magazine Relocation Area would be located in the Central Talofofo Watershed and has the potential to contribute to sedimentation of Fena Valley Reservoir.

Construction activities under Alternative 3 would include clearing of vegetation, grading (cut and fill), permanent or temporary accumulation of soils, stream rerouting, and filling in of natural areas. Potential effects from stormwater runoff would be minimized by adhering to the provisions of the Construction General Permit and implementing of a Program SWPPP and site-specific SWPPP and associated BMPs that would address site- and activity-specific surface water protection requirements. Implementation of construction BMPs under Alternative 3 would also minimize sedimentation impacts to Fena Valley Reservoir.

Construction activities that involve substantial earth moving, and those activities that are within or near stream channels would be scheduled for the dry season (January to May) to the extent possible (NAVFAC Pacific 2013a). Measures to minimize erosion within the project construction footprint, stabilize banks, and protect stream channels would be the same as described under Alternative 2 in Section 5.2.2.2 of this SEIS. Given the short-term nature of potential surface water impacts, compliance with Construction General Permit requirements, and implementation of BMPs, construction activities associated with Alternative 3 would result in less than significant direct and indirect short-term impacts to surface water.

**Groundwater**

Construction activities under Alternative 3 would include stormwater runoff protection measures that would also serve to protect groundwater quality. By adhering to the provisions of the Construction General Permit and implementing BMPs associated with addressing site- and activity-specific water resource protection requirements, there would be a reduction in stormwater pollutant loading potential and thus a reduction in pollution loading potential to the underlying groundwater basins. Given stormwater runoff protection measures (i.e., compliance with Construction General Permit requirements and implementation of BMPs), construction activities associated with Alternative 3 would result in less than significant direct short-term impacts to groundwater.

**Nearshore Waters**

Construction activities under Alternative 3 would occur more than 1.0 mile (1.6 km) from the coastline and would not result in direct impacts to the nearshore waters from stormwater runoff. Compliance with the Construction General Permit and implementation of BMPs under Alternative 3 would protect water quality in the Talofofo River and ensure that stormwater runoff from the project area would not cause indirect impacts to nearshore waters in Talofofo Bay (see Figure 5.2.2-1). Given stormwater runoff protection measures (i.e., compliance with Construction General Permit requirements and implementation of BMPs), construction activities associated with Alternative 3 would result in no impacts to nearshore waters.
Wetlands

Implementation of Alternative 3 could result in long-term, direct impacts to up to 36.9 acres (15.0 ha) of potentially jurisdictional wetland areas (see Figure 5.3.2-1). These direct impacts would be at the MPMG and KD Rifle ranges and range roads. There are an additional 0.7 acre (0.3 ha) of NWI wetlands in portions of the project area that have not been surveyed (see Section 5.3.2.1 in this SEIS).

Direct impacts (fill) to jurisdictional wetlands would be a significant impact. If these wetland areas are determined to be jurisdictional by the USACE, and therefore subject to Section 404 requirements, the Marine Corps would first attempt to avoid impacts. If avoidance is not possible, then the Marine Corps would obtain a Section 404 permit from the USACE to fill the wetlands and comply with the potential mitigation measures outlined in the permit (see Table 5.7-1). Unavoidable direct impacts to jurisdictional wetlands would be mitigated by creating new wetlands, restoring or enhancing existing wetlands, or preserving existing wetland areas on Guam to, at a minimum, replace the area filled at a mitigation ratio greater than 1:1.

As described under Alternative 2, a mitigation plan would be prepared under Alternative 3 as part of the Section 404 permitting process. If Alternative 3 is chosen and wetlands cannot be avoided, the Marine Corps understands that a LEDPA determination must be made as part of the permitting process and that if the USACE determines this alternative is not the LEDPA, a Section 404 permit under the CWA cannot be granted and Alternative 3 would not be implemented. Through implementation of the potential mitigation measures and procedures identified above, significant impacts to wetlands would be reduced to a level below significant. By comparison, Alternatives 1 and 5 would have no impacts to wetlands and Alternatives 2 and 4 would have significant long-term, direct impacts to up to 17.7 acres (7.2 ha) and 25.2 acres (10.2 ha) of potentially jurisdictional wetland areas, respectively, which would be mitigated to a level below significant.

There would also be potentially jurisdictional wetlands adjacent to and downstream of construction areas that would be subject to potential indirect impacts during construction. These short-term, indirect impacts would be minimized by adhering to the provisions of the Construction General Permit and implementing BMPs associated with addressing site- and activity-specific stormwater runoff protection requirements.

Operation

Alternative 3 would incorporate the concept of LID in the final planning, design, and permitting of the stormwater runoff and drainage design as described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.1: North, pages 4-85 to 4-87) and under Alternative A in Section 4.1.2.2 of this SEIS. Operation impacts associated with the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.2.2 of this SEIS.

Under Alternative 3, there would be a minor increase in the area of impervious surface as a result of ranges and associated support facilities, which would result in an associated increase in stormwater discharge intensities and volume. However, the proposed action would incorporate LID measures and BMPs to ensure stormwater retention would be consistent with local and federal requirements and thus minimize potential impacts to surface water quality. Alternative 3 would also be implemented in accordance with all applicable orders, laws, and regulations including the preparation and implementation of a SWPPP, SWMP, and SPCC plan that would control runoff and minimize potential leaks and spills. Where possible, stormwater flow paths would continue to mimic pre-development flows through area topography.
Alternative 3 would include implementation of the REVA program and range management preventative measures (i.e., vegetation, pH adjustment, LID). As listed in Section 2.8 of this SEIS, the BMPs would reduce the potential for contaminants to migrate off-site. In addition, the DoD would investigate additional technologies that could assist with range design and management to minimize potential impacts. Available baseline data regarding range site conditions would be reviewed and verified prior to range construction and regular monitoring would occur during operations to verify the effectiveness of BMPs. For each range, water quality treatment strategies would be selected to achieve reductions of non-point source pollutants to meet the same water quality requirements as identified under Alternative A in Section 4.1.2.2 of this SEIS.

Surface Water

The Watershed Reconnaissance Study (NAVFAC Pacific 2013a) identified potential direct and indirect impacts to surface waters during the operational phase of Alternative 3, as described under Alternative 2 in Section 5.2.2.2 of this SEIS (see Appendix F). Potential effects from stormwater runoff would be minimized through the implementation of an appropriate and comprehensive stormwater management plan utilizing a LID approach and BMPs under Alternative 3. Firing range operational-phase LID measures and BMPs would focus on reducing volume and velocity of stormwater runoff, minimizing soil erosion potential within the range boundaries, and controlling the spread of lead bullets and bullet fragments. Implementation of the REVA program and BMPs for containing and limiting off-site migration of lead contaminants would be the same as described under Alternative 2 in Section 5.2.2.2 of this SEIS and are listed in Section 2.8 of this SEIS.

Appropriate fire suppression and potential mitigation measures would also be incorporated into the design (fire resistant structures) and range operating procedures as described under Alternative 2 in Section 5.2.2.2 of this SEIS. Alternative 3 would have a reduced fire susceptibility compared to Alternative 2. The existing Wildland Fire Management Plan (USFS 2008) that covers NAVMAG would continue to be implemented under Alternative 3. Therefore, the risk of exposing soils to erosion due to arson or natural wildland fires would be relatively low under Alternative 3 because the ranges would be located within NAVMAG.

Because none of the proposed Alternative 3 firing range footprints fall within the Central Talofofo Watershed, stormwater runoff from the proposed range footprint areas would not drain to the Fena Valley Reservoir. The Magazine Relocation Area would be located in the Central Talofofo Watershed and has the potential to contribute to sedimentation of Fena Valley Reservoir. However, the magazine would include appropriate LID measures and BMPs to minimize erosion within the project construction footprint and transport of sediment to surface waters. The SDZ associated with Alternative 3 would partially overlay the Central Talofofo Watershed (see Figure 5.3.2-1), but potential impacts to the water quality of Fena Valley Reservoir from expended projectiles would be negligible as described under Alternative 2 in Section 5.2.2.2 of this SEIS.

No buildings/structures would be constructed in the 100-year or 500-year flood zone. It is anticipated that developing the proposed footprint areas would not impact water surface elevation levels in FEMA-regulated floodplains. However, this would be confirmed through detailed hydraulic and hydrologic modeling during the final design phase. Any rise in the elevations would be covered by FEMA regulations and would need to be approved by the local floodplain administrator.

Alternative 3 would be conducted in accordance with all applicable orders, laws, and regulations including the preparation and implementation of a SWPPP, SWMP, and SPCC Plans that would control runoff and minimize potential leaks and spills. Given implementation of these stormwater runoff
protective measures and range operation BMPs for containing and limiting the migration of lead contaminants, operations associated with Alternative 3 would result in less than significant direct or indirect long-term impacts to surface water.

Groundwater

Under Alternative 3, proposed operations would be in compliance with the stormwater runoff protection measures identified above that would also serve to protect groundwater quality and recharge. Specifically, implementation of LID measures and the provisions of the SWPPP and associated erosion control activities would ensure that any stormwater runoff recharging to groundwater basins would be of acceptable quality. BMPs to minimize lead transport would minimize contamination of groundwater. Given stormwater runoff protection measures (e.g., implementation of the REVA program, LID, and SWPPP measures), operations associated with Alternative 3 would result in less than significant long-term, direct impacts to groundwater.

Nearshore Waters

Under Alternative 3, proposed operations would be in compliance with the stormwater runoff protection measures identified above that would also prevent direct impacts to the nearshore waters from stormwater runoff. Implementation of LID measures and BMPs under Alternative 3 would protect water quality in the Talofofo River and ensure that stormwater runoff from the project area would not cause indirect impacts to nearshore waters in Talofofo Bay. Given stormwater runoff protection measures (i.e., implementation of LID, BMPs, and pollution prevention plans), operations associated with Alternative 3 would result in no impacts to nearshore waters.

Wetlands

Under Alternative 3, proposed operations have the potential to cause indirect effects to nearby down-gradient wetland areas (see Figure 5.3.2-1). However, the stormwater runoff protection measures identified above would also serve to protect water quality entering wetlands. Specifically, implementation of LID measures and the provisions of the SWPPP and associated erosion control activities would ensure that the stormwater runoff flowing into wetlands would be of acceptable quality. Given stormwater runoff protection measures (i.e., implementation of LID, BMPs, and pollution prevention plans), operations associated with Alternative 3 would result in less than significant long-term, indirect impacts to wetlands.

5.3.3 Air Quality

5.3.3.1 Affected Environment

The areas around Alternative 3 are not developed and no sensitive populations are present. Ambient air quality conditions in these areas can be considered typical for a rural area and include few activities involving operation of major stationary or mobile sources.

5.3.3.2 Environmental Consequences

Construction activities under Alternative 3 would be similar to Alternative 1, with the exception of site location. Therefore, the predicted construction activity annual emissions would be the same as Alternative 1, as summarized in Table 5.1.3-2. Emission would be well below the significance criterion of 250 tpy.

The hot-spot air quality impacts during both construction and operational phases would be similar to Alternative 1, as discussed in Section 5.1.3; resulting in less than significant short- and long-term hot-spot air quality impacts.
5.3.4 Noise

5.3.4.1 Affected Environment

Generally similar to the area southeast of NAVMAG, the mountainous southern-central portion of Guam contains Fena Valley Reservoir and NAVMAG, with very few people residing in areas that are immediately adjacent to the north portion of NAVMAG. The community of Santa Rita lies to the north and west over a small hill. Current noise sources in this area include light traffic noise and noise consistent with suburban neighborhoods. Acoustically, this area would be typical of a rural/suburban setting with ambient noise levels in this area of approximately 45-55 dBA (USEPA 1978).

5.3.4.2 Environmental Consequences

Construction

There would be no impact due to construction noise under Alternative 3 because construction activities would be in a sparsely populated area of Guam. Construction areas would be approximately 0.25 mile (0.4 km) away from the nearest receptors, a distance that is far enough away from the source of construction noise such that there would be minimal noise effects on receptors.

Operation

Alternative 3 would be located on the east slope of the ridgeline separating NAVMAG from the community of Agat and Santa Rita. Under Alternative 3, Zone 2 noise contours cover approximately 31 acres (12 ha) beyond the boundaries of NAVMAG and Zone 3 would all be within NAVMAG property. The off-base acreage would extend towards the north and west of NAVMAG. Modeling results (Army 2013) for Alternative 3 are shown on Figure 5.3.4-1. No houses are present within the noise contours so no residents would be affected by Zone 2 or Zone 3 noise contours. Approximately 70-80 homes would be within the Zone I noise contours in the area along Route 12 adjacent to Our Lady of Guadalupe Church and would experience noise levels between 55 and 60 dB ADNL. Another approximately 100 homes would be within the Zone 1 contours in Agat near the Pagachao Guam Housing and Urban Renewal Authority housing area with noise levels of 55 to 68 dB ADNL. Although noise would be greater than existing levels, this area would still be considered compatible for residential use. Noise may be less than predicted because the area is on the opposite side of the hill from the proposed firing line and the area is heavily wooded. Both of these factors attenuate sound levels. Table 5.3.4-1 lists Noise Zones 2 and 3 and the associated acreage affected within each zone.

Source: NAVFAC Pacific 2013
Under Alternative 3, no people would be impacted by Zone 2 or 3 noise levels because there are no residences within these zones. There would be no direct impacts due to live-fire training noise under this alternative because there would be no populated residential areas affected and none of the noise significance criteria stated in the Marine Corps Guidance memo for land use and noise exposure would be exceeded (Marine Corps 2005). There would be no direct or indirect impacts because no population would be affected, and none of the impact assessment criteria related to potential noise impacts would be exceeded. As described in Section 5.1.4.2, noise levels at the HG Range would remain within Andersen South and not impact any residences. In summary, there would be no residences/households affected by noise resulting from implementation of Alternative 3 and, consequently, no significant noise impacts would occur.

In comparison, Alternative 1 is the only LFTRC alternative that would potentially result in significant noise impacts, so the significance of Alternative 3 noise impacts is less than Alternative 1 and the same as Alternatives 2, 4 and 5.

### 5.3.5 Airspace

#### 5.3.5.1 Affected Environment

The existing airspace conditions for Alternative 3 would be the same as described for Alternative 1 in Section 5.1.5.1. Detailed information on military and civilian air traffic associated with AAFB and Guam International Airport, respectively, is provided in the 2010 Final EIS (Volume 2, Chapter 7: Airspace, Section 7.1.2: Military Air Traffic, pages 7-8 to 7-10).

#### 5.3.5.2 Environmental Consequences

**Construction**

No changes to airspace would be required during construction of the LFTRC under Alternative 3. Construction activities would not be expected to conflict or interfere with the use or management of existing airspace in the vicinity. Therefore, construction of the LFTRC under Alternative 3 would have no impact on airspace.

**Operation**

Figure 5.3.5-1 depicts the proposed Restricted Area associated with the LFTRC at NAVMAG (North/South). This SUA would be needed to contain the vertical hazard associated with the proposed live-fire training. Boundary coordinates for the proposed NAVMAG (North/South) Option A of R-7202 Guam would begin at:

- lat.13°22'56"N., long.144°39'54"E
- to lat.13°22'0"N., long.144°41'34"E
- to lat.13°19'54"N., long.144°41'54"E
- to lat.13°19'39"N., long.144°39'57"E
- to the point of beginning
Figure 5.3.5-1
Proposed SUA Associated with LFTRC Alternative 3

Source: NAVFAC Pacific 2013
Altitudes, times of use, and controlling and using agencies for this Restricted Area SUA would be the same as described in Section 5.1.5.2 for Route 15 LFTRC Alternative. The proposed CFA associated with the HG Range at Andersen South would be the same as described in Section 5.1.5.2 and depicted in Figure 5.1.5-4.

Section 3.5.3.1 identifies the potential impacts to airspace from implementation of the LFTRC alternatives. Given its location, Alternative 3 would directly impact arrivals into and departures out of Guam International Airport. The FAA stated in the preliminary Airspace Feasibility Assessment (FAA 2013) that Alternative 3 is not feasible. However, the FAA stated that “an assignment of ‘not feasible’ to a specific alternative is not a statement of infeasibility, but merely an assessment of the airspace in regard to the level of assumed impact” (FAA 2013).

Operational activities under Alternative 3 have the potential for significant direct long-term impacts to aviation due to the following:

- Guam International Airport Airspace and instrument approach procedures.
- IFR/VFR traffic flows.
- Terminal operations.

However, if this alternative is selected, long-term impacts and potential mitigation would be further studied through the DON/FAA/Air Force consultation process. The general types of potential mitigation measures that could be employed may include adjusting airspace per FAA coordination and/or adjusting LFTRC operation procedures if feasible. However, no specific potential mitigation measures are proposed at this time.

As detailed in Table 5.7-1, operational impacts under Alternative 3 would be the same as under Alternatives 1, 2, and 4. Operational impacts under this Alternative would be greater than impacts under Alternative 5.

5.3.6 Land and Submerged Land Use

5.3.6.1 Affected Environment

All LFTRC alternatives include a HG Range at Andersen South, the affected environment and impacts of which are described in Section 5.1.6.

The proposed Alternative 3 would be located almost entirely within the NAVMAG boundary, but does require some land acquisition (Figure 5.3.6-1). The acreages to be acquired are described in Section 2.5.4.7. Summary of LFTRC Alternatives, Table 2.5-3. No land acquisition is proposed for utility infrastructure or access roads. No submerged land would be affected.

The primary existing land use for NAVMAG is as described in Section 5.2.6. The LFTRC would require relocation of existing NAVMAG munitions storage facilities within NAVMAG.

All of the land proposed for acquisition is undeveloped and in its natural state (Appendix D SIAS; Figure 5.3-14, Table 5.3-3).

There are no land use plans for the community around the NAVMAG area of Guam. The GBSP land classification for the proposed acquisition area is Agriculture (see Figure 3.6.1-2). No current agricultural use was identified in the aerial photographs.
Figure 5.3.6-1

Sources: DON 2010, NAVFAC Pacific 2013
Adjacent land uses to the Alternative 3 impacted area are other NAVMAG land uses and non-federal lands that are classified by GBSP as Agriculture (see Figure 3.6.1-2).

Mount Lamlam and Mount Jumullong Manglo were identified west of the SDZs, but not adjacent (see Figure 5.3.6-1).

No human sensitive noise receptors were identified adjacent to Alternative 3, but Santa Rita Village is located north of the ranges.

5.3.6.2 Environmental Consequences

Land use impacts are addressed in this section. Land ownership impacts are addressed in Section 5.3.15, Socioeconomics and General Services.

Construction

As previously discussed in Chapter 3, Section 3.6.3.1, all changes in land use are considered long-term operational impacts. Therefore, there is no construction-phase analysis for this resource under any of the alternatives.

Operation

Potential impacts on Fena Valley Reservoir and water supply are addressed in Section 5.3.2.2, Water Resources. The wellhead protection areas would not be affected. LFTRC land use would be compatible with the existing military NAVMAG land use, except the use of the southern land navigation area would be discontinued and some magazines would need to be relocated. Any land use incompatibility issues related to the military mission within NAVMAG would be resolved through application of installation master planning guidelines outlined in UFC 2-100-01. Therefore, direct long-term land use impacts to NAVMAG would be less than significant.

No direct or indirect significant impact to existing land use or GBSP classification of Agricultural land use was identified within or adjacent to the land acquisition area. No USDA-designated prime farmland was identified. Less than 1% of the total Guam USDA-designated important farmland was identified in the acquisition area. This is considered a less than significant indirect long-term impact because it is not currently in agricultural use and there are other prime and important farmlands available for agricultural use. The acquired area would largely remain as open space.

Land use impacts related to other resource areas are covered under various sections of this SEIS, such as socioeconomic, recreational, water or noise. As addressed under Cultural Resources (Section 5.3.10) and Recreational Resources (Section 5.3.7), public access to Mount Lamlam and Mount Jumullong Manglo would not be impacted. The public would be restricted from entering the acquired lands. However, no educational, cultural or recreational sites were identified that would be affected by the restrictions. There would be no long-term impact related to access.

The proposed Alternative 3 would be compatible with the surrounding vacant land use. Zone 3 contours would not extend off-base. Zone 2 noise contours would extend beyond the proposed installation boundary, as described in Section 5.3.4.2, Noise and shown on Figure 5.3.4-1. However, no existing or planned residential land uses (or other sensitive receptors like schools or medical facilities) were identified within the Zone 2 contour. The acquisition area is designated for Agriculture, which is a compatible use within the Zone 2 noise contour. No impact on land use is anticipated.

Due to the lack of impacts to land use resources, Alternative 3 would have the least impact compared to all of the other LFTRC alternatives.
5.3.7 Recreational Resources

5.3.7.1 Affected Environment

Recreational resources within or adjacent to Alternative 3 are the same as those discussed in Section 5.2.7 for Alternative 2.

5.3.7.2 Environmental Consequences

As discussed in the 2010 Final EIS, access to, and use of, recreational resources at NAVMAG is restricted to installation personnel and guests (Volume 2, Section 9.1.5.1: Naval Munitions Site, Table 9.1-7: Recreational Resources on Naval Munitions Site and Public Access, page 9-14). While the nature of the potential proposed uses at or near NAVMAG has changed from the 2010 Final EIS, the potential impacts or lack of impacts remains the same. In the North-South alternatives, only a small portion of the SDZ extends outside NAVMAG property and there are no recreational resources that would be impacted by use of this area for LFTRC activities.

Construction

During construction activities, the short-term increase of construction-related vehicles on roads may cause delays to persons accessing recreational areas. Although staged construction equipment would not obstruct access to, or the use of, recreational resources, inconveniences to resource seekers (e.g., potential detours, longer waits, and other similar nuisances) would result. However, construction of Alternative 3 would not substantially reduce recreational opportunities, cause substantial conflicts between recreational users, or cause substantial deterioration of recreational resources. Therefore, short-term less than significant direct impacts to recreational resources would be anticipated.

Operation

Portions of SDZs are proposed outside NAVMAG property and to the east. These parcels would need to be acquired and would become federally owned property. Therefore, access to the public would be limited. In addition to access restrictions, there are potential indirect impacts from firing range noise, which could lessen visitor enjoyment of publicly accessible recreational resources in the area of the LFTRC. However, direct and indirect long-term impacts would be less than significant for the following reasons:

- The 2010 Final EIS states that the impacts are less than significant at the NAVMAG site. Even though the current East/West and L-Shaped NAVMAG LFTRC alternatives extend eastward from NAVMAG and would require land acquisition, there are no identified recreational resources in those areas that would be directly or indirectly affected by land acquisition.

- The construction of the access road for the East/West and L-Shaped NAVMAG LFTRC alternatives would make access to the area easier for the public during those times the ranges are not in operation.

Known recreational resources in the area (primarily Talofofo Falls) would not be impacted by noise during training.
5.3.8 Terrestrial Biological Resources

5.3.8.1 Affected Environment

Vegetation Communities

Figure 5.3.8-1 depicts the vegetation communities within NAVMAG associated with the proposed Alternative 3. The vegetation communities were mapped based on the following sources:

- USFS (2006) - island-wide coarse-scale mapping used as the starting point.
- Field surveys conducted in 2012 (NAVFAC Pacific 2013a) in notional range areas for more fine-scale mapping (some range locations were subsequently revised).
- COMNAV Marianas (2001) - Merrilliodendron forest locations.

Vegetation types are described in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.1.1: Vegetation Communities, pages 10-1 to 10-6). NAVMAG contains some of Guam’s most remote, inaccessible terrestrial habitat and diverse vegetation communities. Portions of the western part of the action area consist of rugged limestone terrain of sharp pinnacles, towers and narrow fissures that supports a relatively pristine primary limestone vegetation community. For additional description of vegetation communities within NAVMAG, see the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.5.3: pages 10-76 to 10-77).

Terrestrial Conservation Areas

The majority of NAVMAG, including the impacted areas (i.e., physical disturbance for range footprints) of the Alternative 3 action area, is within established Overlay Refuge (see Figure 5.2.8-2). Additional information on Overlay Refuge lands is provided in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.1.3: Special-Status Species, pages 10-8 to 10-11).

Wildlife - Native Species

The only native migratory bird species observed in project-specific studies in the proposed Alternative 3 action area on NAVMAG were the yellow bittern and fairy tern (NAVFAC Pacific 2010, 2013a). General observations of migratory birds in southern Guam from the National Audubon Society’s Christmas Bird Counts (National Audubon Society 2013) are described in Section 5.2.8.1.

During surveys conducted for this SEIS, three native reptile species (in addition to two Guam-listed species, discussed below) were observed within the forested areas of the proposed Alternative 3 action area: Pacific blue-tailed skink, mourning gecko, and mutilating gecko (NAVFAC Pacific 2013a).

The Talisay and Bonya rivers that drain into Fena Reservoir are present in the Alternative 3 action area. As noted in the 2010 Final EIS, there is limited information for Guam’s freshwater ecosystems and it is not specific to the lands in this alternative (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.5.3: Naval Munitions Site - Freshwater Invertebrates and Fish, pages 10-77 to 10-78). However, relevant and applicable studies for the NAVMAG area were summarized in the 2010 Final EIS; no new information since the 2010 Final EIS is available.

Additional information on native wildlife species occurring within the NAVMAG is provided in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.5.3: Naval Munitions Site, page 10-77).
Surveys conducted in 2009, 2010, 2012 and 2013 for the 2010 Final EIS and this SEIS observed a number of non-native species within NAVMAG. Non-native bird species observed within the Alternative 3 action area included the island collared dove, black drongo, and black francolin. Four non-native reptile and four amphibian species were found within the forested areas of the NAVMAG: curious skink, house gecko, brown treesnake, monitor lizard, marine toad, greenhouse frog, eastern dwarf tree frog, and Gunther’s Amoy frog (NAVFAC Pacific 2010, 2013a).

Additional information on other non-native species at NAVMAG, including Asiatic water buffalo (or carabao), Philippine deer, feral pigs, brown treesnake, and freshwater invertebrates and fish, is provided in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.5.3: Naval Munitions Site, pages 10-78 to 10-79).

**Special-Status Species: Federal ESA-Listed and Proposed Species**

Two ESA-listed (Mariana fruit bat and Mariana common moorhen) and three proposed species (Mariana eight-spot butterfly, *Tabernaemontana rotensis*, and *Cycas micronesica*) occur within or in the vicinity of the proposed Alternative 3 ranges (Table 5.3.8-1 and Figure 5.2.8-3). Although “suitable habitat” for special-status species is present within the Alternative 3 project areas, the brown tree snake, the primary factor in the extirpation of special-status wildlife species on Guam and one of the largest obstacles to achieving recovery of special-status species, is still considered abundant and widespread on Guam. Until brown treesnakes are suppressed or removed from at least targeted areas on Guam, the habitat is not in a suitable condition to support the survival of special-status species due to current snake abundance on Guam (e.g., Guam Micronesian kingfisher, Guam rail, Mariana crow) (USFWS 2010a).

In addition to the discussion below, additional information for individual species at NAVMAG is provided in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.5.3: Naval Munitions Site, ESA-listed and Candidate Species, pages 10-79 to 10-84).

**Mariana Fruit Bat.** After 1996, an estimated 5-20 individual Mariana fruit bats were thought to occur within the NAVMAG/Upper Talofofo Watershed, and were assumed to be full time residents of the area, rather than migrants from the main Pati Point Colony on AAFB in northern Guam (Morton and Wiles 2002). USFWS (1996) speculated that disturbance associated with illegal hunting may have inhibited the establishment of a communal roost within NAVMAG. Currently, fruit bats are only occasionally observed at NAVMAG. During dawn and dusk observations on 42 different days between February and July 2008, only one bat was sighted along Almagosa Road (Brooke 2008). Surveys conducted in 2012 within the Alternative 3 action area for this SEIS observed solitary Mariana fruit bats within ravine forest on 6 separate days (see Figure 5.2.8-3) (NAVFAC Pacific 2013a). The sightings were generally within the same area and just north of the Brooke (2008) observation. Fruit bat recovery habitat is found within proposed project impacted areas and SDZs associated with Alternative 3 (see Figure 3.8.3-1).

**Mariana Common Moorhen.** The moorhen is a freshwater obligate species and inhabits emergent vegetation in freshwater marshes and ponds. As described in the 2010 Final EIS, the largest moorhen population was historically at Fena Reservoir. However, conditions in the reservoir have changed, causing moorhens to find more suitable habitat elsewhere. The decrease in suitable habitat seems to be a result of the decline of *Hydrilla verticillata*, a water plant used by moorhens as a nesting substrate (JRM 2013). The current population on Guam is estimated at 100-150 birds (USFWS 2012b).

Surveys in 2012 within the Alternative 3 action area documented moorhens on two ponds (see Figure 5.2.8-3). A single moorhen was observed on 2 separate days on a pond in the eastern portion of the action area within the northwest corner of the proposed KD Rifle Range (NAVFAC Pacific 2013a). A single
moorhen was also observed on 1 day on a pond located in the western portion of the proposed Alternative 3 ranges and just southwest of the range area associated with the proposed MPMG Range.

**MARIANA SWIFTLET.** Swiftlets nest and roost in caves and leave the caves during the day to forage over a wide variety of terrain and vegetation, favoring ridge crests and open grassy areas where they capture small insects while flying (USFWS 1991). There are only three known nesting/roosting caves (Mahlac, Fachi, and Maemong) on Guam for this species and they are located in the northern NAVMAG approximately 1 mile (1.6 km) east of the proposed Alternative 3 action area (see Figure 5.2.8-3).
number of swiftlets at Mahlac cave fluctuates around 1,000, while the number at Maemong cave from 2010 to 2012 ranged between 40 and 126, and at Fachi cave have fluctuated between a low of 3 (2011) and a high of 172 (2009) (Brindock 2012). Although potential foraging habitat occurs within the action area, no Mariana swiftlets were observed during 2008, 2009, and 2012 surveys within the Alternative 3 action area (NAVFAC Pacific 2010, 2013a).

MARIANA CROW. The Mariana crow was last observed in southern Guam in the mid-1960s (USFWS 2005). Since 2009, the population on Guam consisted only of two males on AAFB, occurring primarily within the MSA (USFWS 2009c). However, as of 2012, the Mariana crow is considered extirpated in the wild on Guam (Personal communication via letter from USFWS, Pacific Islands Fish and Wildlife Office, Honolulu, HI regarding the DON NOI for Proposed Placement of LFTRC on Guam NWR; December 7, 2012). The closest population of crows is on the island of Rota, approximately 56 miles (90 km) north of Guam. Crows in northern Guam used primary limestone forest for nesting, with nests exclusively in native trees. They have been observed foraging in both primary and secondary limestone forests and tangantangan (USFWS 2005). Crow recovery habitat is found within proposed project impacted areas and SDZs associated with Alternative 3 (see Figure 3.8.3-1).

GUAM RAIL. The Guam rail was last seen in southern Guam in the 1970s, and was extirpated in the wild by 1985. It exists primarily in captivity on Guam and in mainland zoos. Experimental populations of Guam rails were introduced onto Rota, CNMI in 1989 and onto Cocos Island, off the southern coast of Guam, in 2011 (USFWS 2009b; BirdLife International 2013). The Guam rail prefers edge habitats, especially grassy or secondary vegetation areas which provide good cover; mature forest is deemed only marginal for the Guam rail (USFWS 2009b). Rail recovery habitat is found within proposed project impacted areas associated with Alternative 3 (see Figure 3.8.3-2).

GUAM MICRONESIAN KINGFISHER. The Guam Micronesian kingfisher was last seen in southern Guam in the 1970s, and was extirpated in the wild by 1988. It is now found only in captivity on Guam and at mainland zoos (USFWS 2008). Kingfishers utilized a wide variety of habitats including primary and secondary limestone forest, strand forest, coconut forest, edge habitats, and forest openings, but mature forests with tree cavities suitable for nesting may be an important requirement for kingfisher reproduction (USFWS 2008). Kingfisher recovery habitat is found within proposed project impacted areas and SDZs associated with Alternative 3 (see Figure 3.8.3-1).

SLEVIN’S SKINK. Originally found on Guam, Cocos Island, Rota, Tinian, Guguan, Alamagan, Asuncion, and Maug, it is now limited to Cocos Island, Sarigan, Guguan, Alamagan, Pagan, and Asuncion. Slevin’s skink has not been recorded on Guam since 1945 and is believed to be extirpated from Guam; it is now known to occur only on Cocos Island (an atoll south of Guam) (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 3 (USFWS 2014b). Therefore, as Slevin’s skink is not found within the impacted areas of Alternative 3, this species is not addressed further.

MARIANA EIGHT-SPOT BUTTERFLY. Although the Mariana eight-spot butterfly (adults, larvae, or eggs) was not observed during 2012 surveys within the action area, one large patch and numerous small patches of the host plant Procris pedunculata were observed and mapped within the proposed MPMG Range footprint or 328-foot (100-m) buffers (see Figure 5.2.8-3) (NAVFAC Pacific 2013a).

TREE SNAILS. The three proposed endangered tree snail species (Guam tree snail, humped tree snail, and fragile tree snail) were not observed during field surveys conducted within the proposed Alternative 3 action area in 2009 in support of the 2010 Final EIS and in 2012 in support of this SEIS (NAVFAC Pacific 2010, 2013a, 2013b). In 2008, the Guam tree snail was observed 700 feet (210 m) northwest of the proposed magazine relocation area and approximately 3,000 feet (914 m) southeast of the Non-standard
Small Arms range area (see Figure 5.2.8-3) (Smith et al. 2008), outside of the Alternative 3 impacted area and SDZ. Therefore, as the tree snail species are not found within the Alternative 3 impacted areas, these species are not addressed further.

**SERIANTHES TREE.** The endangered *Serianthes* tree was not observed during field surveys conducted within the proposed Alternative 3 action area in 2009 in support of the 2010 Final EIS and in 2012 in support of this SEIS (NAVFAC Pacific 2010, 2013a, 2013b). The only known location on Guam of the *Serianthes* tree is on AAFB, more than 20 miles (32 km) north of the NAVMAG. However, *Serianthes* recovery habitat is found within proposed project impacted areas and SDZs associated with Alternative 3 (see Figure 3.8.3-2).

**TABERNAEMONTANA ROTENSI AND CYCAS MICRONESICA.** During 2012 surveys, one area of *C. micronesica* and one specimen of *T. rotensis* were observed within the impacted area of the proposed MPMG Range (see Figure 5.2.8-3). The cycad is found in limestone forests throughout Guam and is proposed as an endangered species under the ESA because of the Asian cycad scale insect that is devastating the species (USFWS 2014a).

**HERITIERA LONGIPETIOLATA.** This endemic tree is found in crevices of rough limestone in primary limestone forest (USFWS 2014a). Field surveys for the 2010 Final EIS (NAVFAC Pacific 2010) and in 2012 for this SEIS (NAVFAC Pacific 2013a) did not find *H. longipetiolata* within the proposed range areas under Alternative 3. Two locations of *H. longipetiolata* are known from the southern portion of the proposed SDZ and one individual is recorded just south of the proposed munitions magazine relocation area (see Figure 5.2.8-3). As *H. longipetiolata* has not been observed within the proposed impacted areas of Alternative 3, this species is not addressed further.

**BULBOPHYLLUM GUAMENSE.** An epiphyte in the orchid family, this species occurs in mat-like formations on tree branches of coastal lowland/limestone forests. Currently, there are 8 known occurrences on Guam totaling fewer than 250 individuals. There is one occurrence in the northern NAVMAG east of the main gate (Figure 5.2.8-3) (USFS 2014a). There are no records of the species within the impacted areas of Alternative 3 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *B. guamense* is not found within the impacted areas of Alternative 3, this species is not addressed further.

**EUGENIA BRYANII.** A perennial shrub in the myrtle family, the species is known only from the island of Guam. Historically, *E. bryanii* is known from windy exposed coastal cliffine and along the Pigua River, in lowland/limestone forests. Currently, *E. bryanii* is known from 6 occurrences totaling fewer than 420 individuals (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 3 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *E. bryanii* is not found within the impacted areas of Alternative 3, this species is not addressed further.

**MAESA WALKERI.** A shrub or small tree in the primrose family typically found in limestone forests, this species is known from only two individuals on Guam, one of which is located along the southwestern border of the NAVMAG (Figure 5.2.8-3) (USFS 2014a, 2014b). There are no records of the species within the impacted areas of Alternative 3 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *M. walkeri* is not found within the impacted areas of Alternative 3, this species is not addressed further.

**NERVILIA JACKSONIAE.** A small herb in the orchid family, this species is found in lowland/limestone forests. On Guam, *N. jacksoniae* is known from two occurrences totaling fewer than 200 individuals (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 3.
Therefore, as \textit{N. jacksoniae} is not found within the impacted areas of Alternative 3, this species is not addressed further.

**Psychotria Malaspiniae.** A shrub or small tree in the coffee family, this species is found in lowland/limestone forests. Currently, \textit{P. malaspiniae} is known from 5 occurrences. None of these individuals have been observed within the last 5 years (USFWS 2014a, 2014b). There are no records of the species within the impacted areas of Alternative 3 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as \textit{P. malaspiniae} is not found within the impacted areas of Alternative 3, this species is not addressed further.

**Solanum Guamense.** A small shrub in the nightshade family that occurs within limestone forests. Currently, \textit{S. guamense} is known from a single occurrence of one individual on Guam (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 3 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as \textit{S. guamense} is not found within the impacted areas of Alternative 3, this species is not addressed further.

**Tinospora Homosepala.** A vine in the moonseed family found in limestone forests. Currently, \textit{T. homosepala} is known from 3 occurrences totaling approximately 300 individuals (USFWS 2014). There are no records of the species within the impacted areas of Alternative 3 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as \textit{T. homosepala} is not found within the impacted areas of Alternative 3, this species is not addressed further.

**Tuberolabium Guamense.** An epiphyte in the orchid family found in limestone forests. Currently, \textit{T. guamense} is known from 3 occurrences on Guam: 2 occurrences within the NVMAG (1 occurrence in the forest ecosystem of the Mt. Almagosa cliffline and 1 south of the swiftlet caves) (see Figure 5.2.8-3) and 1 at Finegayan (NAVFAC Pacific 2010; USFWS 2014a, 2014b). There are no records of the species within the impacted areas of Alternative 3 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as \textit{T. guamense} is not found within the impacted areas of Alternative 3, this species is not addressed further.

**Dendrobium Guamense.** An epiphyte in the orchid family, the species occurs within lowland/limestone forests and savanna. On Guam, there are 4 occurrences totaling fewer than 250 individuals (USFWS 2014a). There is one known occurrence within the NVMAG within the vicinity of Almagosa Springs (Figure 5.2.8-3). There are no records of the species within the impacted areas of Alternative 3 (USFWS 2014b). Therefore, as \textit{D. guamense} is not found within the impacted areas of Alternative 3, this species is not addressed further.

**Hedyotis Megalantha.** A perennial herb in the coffee family, this species occurs in savanna areas in southern Guam. Currently, \textit{H. megalantha} is known from one large scattered occurrence totaling fewer than 1,000 individuals on southern Guam, between Mt. Alutom and Tarzan Falls. This species typically occurs as lone individuals rather than in patches or groups (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 3 (USFWS 2014b). Therefore, as \textit{H. megalantha} is not found within the impacted areas of Alternative 3, this species is not addressed further.

**Phyllanthus Saffordii.** This woody shrub is currently known from four scattered occurrences on southern Guam within savanna areas: Mt. Alutom, Piti Hills, Nimitz Hill “War in the Pacific Lookout,” and near the Cetti Bay Watershed (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 3 (USFWS 2014b). Therefore, as \textit{P. saffordii} is not found within the impacted areas of Alternative 3, this species is not addressed further.
Special-Status Species: Guam-Listed Species and SOGCN

One Guam-listed species (Pacific slender-toed gecko) occurs within the impacted areas and SDZs of the proposed Alternative 3 (see Table 5.3.8-1). Those species that are also listed under the federal ESA were discussed above.

**Pacific Slender-Toed Gecko.** Field surveys in 2012 documented the Pacific slender-toed gecko within the impacted area of the proposed MPMG Range within the western portion of the Alternative 3 action area (NAVFAC Pacific 2013a) (see Figure 5.2.8-3). Surveys conducted in 2008 and 2009 in support of the 2010 Final EIS, and within the Alternative 3 action area, also observed the Pacific slender-toed gecko within the proposed SDZ associated with Alternative 3 (NAVFAC Pacific 2010).

**Moth Skink.** The moth skink was not observed during surveys conducted in 2012 in support of this SEIS within the impacted areas under Alternative 3 (NAVFAC Pacific 2013a). Surveys conducted in 2008 and 2009 in support of the 2010 Final EIS, and within the Alternative 3 action area, observed the moth skink only within the proposed SDZ associated with Alternative 3 (see Figure 5.2.8-4) (NAVFAC Pacific 2010). As the moth skink has only been observed within the proposed SDZ of Alternative 3, and there would be no ground-disturbing activities within the SDZ, this species is not addressed further.

**Cyathea lunulata.** Field surveys for the 2010 Final EIS (NAVFAC Pacific 2010) and in 2012 for this SEIS (NAVFAC Pacific 2013a) did not find the tree fern *C. lunulata* within the proposed range areas under Alternative 3. As the tree fern has not been observed within the impacted areas associated with Alternative 3, this species is not addressed further.

**Merrilliodendron megacarpum.** During 2012 surveys, several small patches of *M. megacarpum* were observed within the impacted area of the proposed MPMG Range (see Figure 5.2.8-3). *M. megacarpum* is considered an SOGCN because of its rarity and potential threats from ungulate damage, typhoons, development, and insect infestation (GDAWR 2006). *M. megacarpum* is also present in large patches within primary limestone forest in the west-central area of the SDZ (see Figure 5.2.8-3).

5.3.8.2 Environmental Consequences

**Construction**

**Vegetation.** Construction activities under Alternative 3 would remove 105 acres (42 ha) of primary limestone forest, 64 acres (26 ha) of secondary limestone forest, 58 acres (23 ha) of ravine forest, 72 acres (29 ha) of herbaceous scrub, 38 acres (15 ha) of savanna, 52 acres (22 ha) of developed areas, and 3.3 acres (1.3 ha) of forested wetlands (Table 5.3.8-2). Based on surveys conducted in 2012 in the proposed range areas, the ravine forest community is significantly degraded in many areas by invasion of non-native woody plant species including *Vitex* and betelnut palm, and heavy infestation by herbaceous non-native invasive plants (NAVFAC Pacific 2013a). Impacts to vegetation from construction of the proposed HG Range at Andersen South were discussed in Section 5.1.8.2 and were found to be less than significant. Refer to Section 5.3.2.2, *Water Resources*, for a discussion of impacts to wetlands.

Legend: PLF = primary limestone forest; SLF = secondary limestone forest; RF = ravine forest; Sav = savannah; FW = forested wetland; HS = herbaceous scrub; Dev = developed.

Native limestone forest, both primary and secondary, has been significantly reduced on Guam due to past and ongoing actions including extensive disturbance during and after WWII, widespread planting of non-native species; and impacts from non-native ungulates; development; fire; and deforestation. As stated in Section 3.8.1.1, limestone forests on Guam are important since they retain the functional ecological components of native forest that provide habitat for the majority of Guam’s native species, including ESA-listed, ESA-proposed, and Guam-listed species, and Guam SOGCN, as well as maintaining water quality and reducing fire risk. Non-native forest communities (e.g., tangantangan, Vitex) significantly alter the forest structure, composition, and resilience to other disturbance processes and do not provide the conditions suitable for native flora and fauna species to persist (Morton et al. 2000; GDAWR 2006; Guam Department of Agriculture 2010; JRM 2013).

Of the 18,538 acres (7,502 ha) of primary and secondary limestone forest found on Guam, approximately 13,110 acres (5,305 ha) are found primarily within AAFB, Finegayan, and the NAVMAG (USFS 2006). Under Alternative 3, 169 acres (68 ha) of limestone forest and 58 acres (23 ha) of ravine forest would be removed (see Table 5.3.8-2). Ravine forest is also an important community type for native species in southern Guam. Therefore, given the importance of limestone and ravine forest habitats for native species and the continuing loss of native forests across Guam, the conversion of 227 acres (92 ha) of limestone and ravine forest on the NAVMAG to developed area would be a significant but mitigable impact to the regional vegetation community and its function.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct, long-term impacts of proposed construction activities on vegetation communities with implementation of Alternative 3. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the contractor education program.
- **Onsite Vegetation Waste Management Procedures.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the vegetation waste management procedures.
• **DON Guam Landscaping Guidelines.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of landscaping guidelines.

• **LFTRC Range Berm Controls.** To manage stormwater runoff and control erosion, LFTRC range berms would contain native or non-invasive herbaceous vegetation and other engineering controls.

• **Contractor Plans and Specifications.** All construction would occur within the limits of construction shown in the project figures.

**Potential Mitigation Measures**

To mitigate for significant impacts to limestone forest, the DON proposes to implement forest enhancement on a minimum of 227 acres (92 ha) of limestone forest. Forest enhancement would include but is not limited to the following actions:

- Ungulate management consisting of exclusion fencing and active control (i.e. trapping, snaring, shooting) with the goal of eradication within the fenced areas.
- Non-native, invasive vegetation removal.
- Propagation, planting, and establishment of native species that are characteristic of native limestone forest habitats (e.g., *A. mariannensis*, *G. mariannae*, *F. prolixa*, *M. citrifolia*, *W. elliptica*).

The degradation and loss of primary limestone and other forest habitats resulting from ungulate damage and invasion by alien plant species has substantially diminished the extent of habitat for native species in the Mariana archipelago. The anticipated benefit of implementing these potential mitigation measures is improved habitat quality for native flora and fauna, including special-status species. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

**Terrestrial Conservation Areas.** The only terrestrial conservation area within the impacted areas of Alternative 3 is Overlay Refuge. Overlay Refuge lands were established for the purpose of conserving and protecting ESA-listed species and other native flora and fauna, maintaining native ecosystems, and the conserving native biological diversity, recognizing that the primary purpose of lands within the Overlay Refuge is to support the national defense missions of the Navy and Air Force.

Approximately 276 acres (112 ha) of Overlay Refuge lands (Table 5.3.8-3), or 1.3% of the total Overlay Refuge lands on Guam, would be directly impacted under Alternative 3. This area overlaps with the vegetation communities discussed previously. The majority (139 acres [56 ha]) is comprised primarily of limestone forest (Table 5.3.8-3). Therefore, because proposed construction activities would convert 276 acres (112 ha) of Overlay Refuge lands to developed areas, this would be a significant loss to the conservation function of these lands and implementation of Alternative 3 would result in significant but mitigable impacts to terrestrial conservation areas.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct, long-term impacts of proposed construction activities on terrestrial conservation areas with implementation of Alternative 3. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

The same BMPs discussed above under Vegetation would be implemented for terrestrial conservation areas.

**Potential Mitigation Measures**

To mitigate for significant impacts to terrestrial conservation areas, the DON would submit a proposal to CNO Energy and Environmental Readiness Division to designate an ERA on the NAVMAG to conserve native limestone forest in southern Guam which provides habitat for special-status species. The DON has defined an ERA as a physical area or biological unit in which current natural conditions are maintained insofar as possible. These conditions are ordinarily achieved by allowing natural, physical, and biological processes to prevail without human intervention. However, under unusual circumstances, deliberate manipulation (e.g., removal or control of invasive species) may be utilized to maintain the unique feature that the ERA was established to protect (NAVFAC 1996). The proposed NAVMAG ERA would encompass approximately 553 acres (234 ha). Although the proposed NAVMAG ERA is currently part of the Overlay Refuge, implementation of these potential mitigation measures would provide an increased level of protection by further ensuring this area is maintained in natural and near natural conditions and to have available such areas for research and scientific manipulation (NAVFAC 1996; NAVFAC Marianas 2010).

In addition, the DON proposes to submit a proposal to CNO Energy and Environmental Readiness Division to expand the existing Orote ERA by approximately 32 acres (13 ha) of terrestrial habitat. The Final Orote ERA Expansion proposal was completed FY 2013 and will be submitted for approval in 2014.

**Wildlife - Native Species.** Short-term construction noise may temporarily impact suitable habitat for native birds in the vicinity of the construction areas, but they would relocate to other areas of suitable habitat in the vicinity, and could return to the area following construction. Non-listed native reptiles are abundant throughout Guam and impacts to vegetation communities under Alternative 3 would result in less than significant impacts to non-listed native reptile populations. Implementation of Alternative 3 would not have a significant adverse effect on a population of any migratory bird species or other native wildlife species. Impacts to wildlife from the construction of the HG Range at Andersen South were discussed in Section 5.1.8.2 and impacts would be less than significant.

Therefore, as presented above, long-term, direct impacts to populations of native wildlife species would not result because these species are abundant in surrounding areas and could repopulate portions of suitable habitat within the affected area after construction. Therefore, direct impacts to native wildlife species would be less than significant with implementation of proposed construction activities associated with Alternative 3.

Proposed construction activities and associated movement of materials onto and off of Guam could increase the potential for the spread of existing or introduction of new non-native invasive species. To prevent the inadvertent spread of non-native species on Guam or to other locations off of Guam, the DON would implement standard biosecurity measures (e.g., HACCP, brown treesnake interdiction measures,
coconut rhinoceros beetle vegetation management procedures, and outreach/education) into construction protocols, procedures, and activities.

The following BMPs would be implemented to avoid and minimize potential direct, long-term impacts of proposed construction activities on native wildlife with implementation of Alternative 3.

Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

With implementation of these BMPs, including development of HACCP plans and ongoing implementation of standard DON biosecurity protocols regarding detection and management of non-native species (e.g., coconut rhinoceros beetle), the potential for the introduction of new or spread of existing non-native species on Guam is substantially reduced. Therefore, there would be less than significant impacts to native wildlife species related to the potential introduction and establishment of non-native species with implementation of proposed construction activities associated with Alternative 3.

Damage of forested areas, particularly primary and secondary limestone forests, by non-native ungulates (i.e., deer and pigs) is a serious concern on Guam. Under Alternative 3, removal of large amounts of limestone forest currently used by ungulates would displace and concentrate ungulates into adjacent areas, resulting in even higher densities and potentially greater habitat damage. Potential impacts from changes in ungulate densities from construction projects within the same or similar habitat areas as proposed in this SEIS were addressed in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.2.1: North, page 10-115).

The implementation of the potential mitigation measures under the Vegetation section above would also benefit native wildlife species. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures.

**Special-Status Species: Federal ESA-Listed and Proposed Species**

Impacts to special-status species from the construction of the HG Range at Andersen South were discussed in Section 5.1.8.2 and were determined to be less than significant. The following discussion addresses those species that occur within the proposed ranges and SDZs under Alternative 3.

**MARIANA FRUIT BAT.** Approximately 223 acres (90 ha) of Mariana fruit bat recovery habitat would be removed due to proposed construction activities at NAVMAG under Alternative 3. This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

Additional potential direct temporary impacts to the Mariana fruit bat from construction activities are based on the distances from those activities that are likely to cause disturbance to this species (e.g., noise, human activity, lighting). The evaluation of fruit bat disturbance is based on the approach used by
USFWS in previous ESA section 7 formal consultations and associated BOs (e.g., USFWS 2006b, 2010). These distances are: roosting habitat within 492 feet (150 m) and foraging habitat within 328 feet (100 m) from the activity (Wiles, personal communication 2006 and Janeke, personal communication 2006, respectively, as cited in USFWS 2006b).

The species is currently limited to the few areas on Guam away from human activities and with suitable habitat, primarily on federal lands on the NAVMAG and AAFB (JRM et al. 2012a, 2012b; JRM 2013; A. Brooke, NAVFAC Marianas, personal communication). However, illegal hunting, loss and degradation of native forest, predation by the brown treesnake, and the increased extirpation risk owing to the high vulnerability of very small populations continue to limit the potential recovery of the species on Guam (USFWS 2010; JRM 2013). Based on the equilibrium/carrying capacity of snakes on Guam (Rodda and Savidge 2007), implementation of the proposed action is not expected to increase the likelihood of predation by the brown treesnake on Mariana fruit bats.

Although the loss of 223 acres (90 ha) of fruit bat recovery habitat on Guam would not preclude the recovery or survival of the fruit bat, it would reduce the total number of bats that the island can support. Given this loss of recovery habitat and the critically low numbers of bats on Guam, there would be significant but mitigable impacts to the Mariana fruit bat.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct long-term impacts of proposed construction activities on Mariana fruit bats with implementation of Alternative 3. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Pre-Construction Surveys.** Surveys would be completed within suitable fruit bat habitat 1 week prior to onset of construction activities following the USFWS-approved JRM protocol. If a fruit bat is present within 492 feet (150 m) of the project site, the work must be postponed until the bat has left the area.
- **Lighting Installation.** Lighting would be designed to meet minimum safety and AT/FP requirements. Hooded lights would be used to the maximum extent practicable at all new roads and facilities adjacent to fruit bat habitat. Illumination of forest would be kept to an absolute minimum.

**Potential Mitigation Measures**

The same potential mitigation measures discussed previously under Vegetation (i.e., forest enhancement of 227 acres [92 ha] of limestone forest) would be applicable for the Mariana fruit bat and its recovery habitat. The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Mariana fruit bat. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).
MARIANA SWIFTLET. Although the only swiftlet nest/roost caves are approximately 1 mile (1.6 km) east of the proposed LFTRC, surveys within the Alternative 3 action area in 2008, 2009, and 2012 did not observe any Mariana swiftlets within the area. Based on surveys for this SEIS as well as observations from other survey efforts, swiftlets appear to forage to the north, east and south of the caves (Morton and Amidon 1996; NAVFAC Pacific 2010, 2013a, 2013b; R. Spaulding, Cardno TEC, unpublished data). Swiftlets would continue to forage to the north, east and south of the nest/roost caves on the NAVMAG and the drainages of the Mahlac, Maagas, and Talofofo rivers (see Figure 5.2.8-3). The proposed construction activities would also not impact regional insect populations that are the prey base for the swiftlet. Although noise levels within the immediate vicinity of proposed construction activities would increase, they would be localized and temporary. Proposed construction activities would not impact the swiftlet nesting/roosting caves approximately 1 mile (1.6 km) east of the proposed ranges. Therefore, there would be less than significant impacts to the Mariana swiftlet with implementation of the proposed range construction activities under Alternative 3.

MARIANA CROW. The Mariana crow is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the crow is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the crow, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the crow is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative 3, impacts to the crow would be limited to recovery prospects. If crows are reintroduced and exposed to construction activities under Alternative 3, they may be disturbed (DON 2014).

Although the crow no longer occurs on Guam, approximately 230 acres (93 ha) of crow recovery habitat would be removed due to proposed construction activities at NAVMAG under Alternative 3. This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

Although this loss of crow recovery habitat on Guam would not preclude the recovery of the crow should it be reintroduced to Guam in the future, it would reduce the total number of crows that the island can support. If and when the crow is reintroduced to Guam, the best available information indicates project-related noise would not further reduce the amount of recovery habitat suitable for this species’ breeding, feeding and sheltering (USFWS 2010). Given this loss of recovery habitat, there would be significant but mitigable impacts to the recovery of the Mariana crow.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct long-term impacts of proposed construction activities on the recovery of the Mariana crow with implementation of Alternative 3. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- Contractor Education Program. See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

- Brown Treesnake Interdiction. See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

### Potential Mitigation Measures

- Brown Treesnake Suppression or Eradication. See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW for a detailed description of the brown treesnake suppression or eradication program.
- The same potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 227 acres [92 ha] of limestone forest) would be applicable for the Mariana crow and its recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Mariana crow, should it be reintroduced to Guam in the future.

GUAM RAIL. The Guam rail is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the rail is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the rail, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the rail is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative 3, impacts to the rail would be limited to recovery prospects. If rails are reintroduced and exposed to construction activities under Alternative 3, they may be disturbed (DON 2014).

Although the rail no longer occurs on Guam, approximately 24 acres (10 ha) of rail recovery habitat within the proposed magazine relocation area would be removed due to proposed construction activities at NAVMAG under Alternative 3. This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

This loss of rail recovery habitat on Guam would not preclude the recovery or survival of the rail should it be reintroduced to Guam in the future, and it would not substantially reduce the total number of rails that the island can support. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to the Guam rail with implementation of proposed construction activities associated with Alternative 3.

The following BMPs may be implemented to avoid and reduce potential long-term impacts of proposed construction activities on the recovery of the Guam rail with implementation of Alternative 3.

### Best Management Practices

- HACCP Plan. See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
• *Biosecurity Outreach and Education.* See Section 4.1.8.2, *Construction, Vegetation* for a detailed description of biosecurity outreach and education.

• *Contractor Education Program.* See Section 4.1.8.2, *Construction, Vegetation* for a detailed description of the contractor education program.

In addition, potential mitigation measures proposed above for vegetation and the Mariana crow would benefit the Guam rail.

• *Brown Treesnake Suppression or Eradication.* See Section 4.1.8.2, *Construction, Special-Status Species, MARIANA CROW* for a detailed description of the brown treesnake suppression or eradication program.

• The same potential mitigation measures discussed above under *Vegetation* (i.e., forest enhancement of 227 acres [92 ha] of limestone forest) would be applicable for the rail and its recovery habitat. In particular, the objectives of ungulate management, control-suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Guam rail, should it be reintroduced to Guam in the future.

**GUAM MICRONESIAN KINGFISHER.** The kingfisher is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the kingfisher is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the kingfisher, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the kingfisher is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative 3, impacts to the kingfisher would be limited to recovery prospects. If kingfishers are reintroduced and exposed to construction activities under Alternative 3, they may be disturbed (DON 2014).

Although the kingfisher no longer occurs on Guam, approximately 223 acres (90 ha) of kingfisher recovery habitat would be removed due to proposed construction activities at the NAVMAG under Alternative 3. This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

Although this loss of kingfisher recovery habitat on Guam would not preclude the recovery of the kingfisher should it be reintroduced to Guam in the future, it would reduce the total number of kingfishers that the island can support. Given this loss of recovery habitat, there would be significant but mitigable impacts to the recovery of the Guam Micronesian kingfisher.

The following BMPs and potential mitigation measures may be implemented to avoid, minimize, and mitigate potential direct and indirect long-term impacts of proposed construction activities on the recovery of the Guam Micronesian kingfisher with implementation of Alternative 3. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.
Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

Potential Mitigation Measures

- **Brown Treesnake Suppression or Eradication.** See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW for a detailed description of the brown treesnake suppression or eradication program.
- The same potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 227 acres [92 ha] of limestone forest) would be applicable for the rail and its recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the kingfisher, should it be reintroduced to Guam in the future.

MARIANA COMMON MOORHEN. Seasonal and permanent wetlands/ponds that provide suitable habitat for moorhens (i.e., open water) are limited on Guam and the lack of sufficient wetland areas is a limiting factor in the recovery of the species. In 1991 and 2004, there were an estimated 22 seasonal or permanent wetlands on Guam that were utilized by moorhens (Stinson et al. 1991; Takano and Haig 2004a). Most wetlands used by moorhens on Guam are less than 1.5 acres (0.6 ha) in size. Identifying essential wetlands and site fidelity are especially important since wetland habitat is increasingly very limited on Guam. Because most of the large natural wetlands are overgrown with persistent vegetation and dense monocultures of *P. karka*, moorhens are increasingly left with fewer and fewer wetlands to choose from, particularly at the onset of the dry season when seasonal wetlands begin to dry up (Stinson et al. 1991; Takano and Haig 2004a, 2004b).

Implementation of Alternative 3 would directly impact and remove two wetlands that are known to be used by approximately 2-4 moorhens. Based on the limited occurrence of wetlands on Guam that can support moorhens, and their importance in the continued persistence of moorhens on Guam, the loss of 2 wetlands under Alternative 3, or almost 10% of the 22 known wetlands on Guam that are used by moorhens, would be a significant but mitigable impact to the Mariana common moorhen.

The following BMPs and potential mitigation measures may be implemented to avoid, minimize, and mitigate potential direct and indirect long-term impacts of proposed construction activities on the Mariana common moorhen with implementation of Alternative 3. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.
Biosecurity Outreach and Education. See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.

Contractor Education Program. See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

Pre-Construction Surveys. Surveys would be completed within suitable moorhen wetland habitat 1 week prior to onset of construction activities following the USFWS-approved JRM protocol. If a moorhen is present within a wetland within the project site, the work must be postponed until the moorhen has left the area.

Potential Mitigation Measures

Moorhen Habitat Wetland Restoration. The DON may implement wetland restoration in accordance with the recommendations provided in the 2014 Wetland Restoration Feasibility Study.

Mariana Eight-Spot Butterfly. Although adults, larvae or eggs of the eight-spot butterfly have not been observed within the Alternative 3 action area, host plants have been observed within the proposed MPMG Range in the northwest portion of the proposed Alternative 3 (see Figure 5.2.8-3). With implementation of appropriate BMPs to avoid and minimize potential impacts to eight-spot butterflies (e.g., pre-construction butterfly and host plant surveys within the proposed construction footprint and salvage/relocation of host plants, larvae or eggs; see Section 2.8), there would be less than significant impacts to the Mariana eight-spot butterfly with implementation of proposed construction activities associated with Alternative 3. In addition, implementation of the potential mitigation measures described above under Vegetation (i.e., forest enhancement of 227 acres [92 ha] of limestone forest) would also benefit the survival the eight-spot butterfly. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species, including eight-spot butterfly host plants.

Serianthes Tree. Although individual Serianthes trees do not occur within the impacted areas of Alternative 3, approximately 40 acres (16 ha) of Serianthes recovery habitat would be removed due to proposed construction activities at the NAVMAG. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

This loss of Serianthes recovery habitat on Guam would not preclude the recovery of Serianthes, and it would not substantially reduce the total number of Serianthes that the island can support. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to Serianthes with implementation of proposed construction activities associated with Alternative 3.

The following BMPs may be implemented to avoid and minimize, potential direct long-term impacts of proposed construction activities on the recovery of Serianthes with implementation of Alternative 3.

Best Management Practices

HACCP Plan. See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.

Biosecurity Outreach and Education. See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.

Contractor Education Program. See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
The implementation of the potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 227 acres [92 ha] of limestone forest) would benefit Serianthes particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

**Tabernaemontana Rotensis and Cycas Micronesica.** An individual *T. rotensis* and areas of *C. micronesica* were observed within the footprint of the proposed MPMG Range (see Figure 5.2.8-3). Under Alternative 3, all *T. rotensis* and *C. micronesica* would be avoided to the maximum extent practicable during proposed construction activities. In addition, high-value (both biologically and culturally) plant species, such as *T. rotensis* and *C. micronesica* would be salvaged to the maximum extent practicable during construction activities and translocated to suitable habitat on the NAVMAG (see Section 2.8). Therefore, with implementation of the previously mentioned BMPs (e.g., avoidance, or salvage and translocation), there would be less than significant impacts to *T. rotensis* and *C. micronesica* with implementation of the proposed construction activities associated with Alternative 3.

**Special-Status Species: Guam-Listed and SOGCN**

Pacific Slender-Toed Gecko. The Pacific slender-toed gecko is listed by Guam as endangered. This species is threatened primarily by introduced species (e.g., feral ungulates, curious skinks, musk shrews, rats, brown treesnakes, and feral cats) and loss of limestone forest habitat. The gecko is known from primary and secondary limestone forest in the Alternative 3 impacted area of the proposed MPMG Range (see Figure 5.2.8-3). The full extent of the distribution and abundance of this species throughout Guam has not been assessed. The loss of approximately 169 acres (68 ha) of occupied gecko habitat with implementation of construction activities under Alternative 3 would be a significant but mitigable impact to the Pacific slender-toed gecko.

The following BMPs and potential mitigation measures may be implemented to avoid, minimize, and mitigate potential direct long-term impacts of proposed construction activities on the slender-toed gecko with implementation of Alternative 3. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

**Potential Mitigation Measures**

The potential forest enhancement mitigation measures described above in the Vegetation section would also result in a conservation benefit to the Pacific slender-toed gecko. The proposed brown treesnake research and suppression may also benefit this species. See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW potential mitigation discussion for more information.

**Merrilliodendron Megacarpum.** An area of *M. megacarpum* was observed within the footprint of the proposed MPMG Range (see Figure 5.2.8-3). Under Alternative 3, all *M. megacarpum* would be avoided to the maximum extent practicable during proposed construction activities. In addition, high-value (both biologically and culturally) plant species, such as *M. megacarpum* would be salvaged to the maximum
extent practicable during construction activities and translocated to suitable habitat on the NAVMAG (see Section 2.8). Therefore, with implementation of the previously mentioned BMPs (e.g., avoidance, or salvage and translocation), there would be less than significant impacts to *M. megacarpum* with implementation of the proposed construction activities associated with Alternative 3.

**Operation**

**Vegetation.** With implementation of BMPs (see previous discussion of construction impacts under *Vegetation*), including ongoing implementation of standard DON and commercial biosecurity protocols (e.g., Port of Guam, A.B. Won Pat International Airport) regarding detection and management of non-native species, invasive species outreach and education, applicable elements of the SIP, and 1-year post construction monitoring to evaluate effectiveness of HACCP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of Alternative 3 is considered unlikely.

Fire potential would increase due to proposed live-fire range operations. Fire can result in direct effects to vegetation by increasing erosion, allowing for the establishment of non-native species, and altering wildlife habitat by reducing food resources, breeding habitat, and shelter. Native plants and their habitats on Guam are adapted to a humid, tropical climate and are not adapted to a fire driven ecosystem (USFWS 2008a). Fire is a serious problem on Guam. Fire history records available from 1979 - 2002 indicate that over this 23-year period more than 16,000 fires have occurred in Guam (averaging more than 700 per year) that have burned in excess of 100,000 acres (40,469 ha), primarily in southern Guam. Of these 16,000 fires, 477 of them occurred on Naval Base Guam, primarily at Apra Harbor and NAVMAG, burning more than 9,800 acres (3,966 ha) (Nelson 2008).

As a BMP and in accordance with range safety protocols, a Range Fire Management Plan would be prepared, based on the DON’s Wildland Fire Management Plan (Nelson 2008) (see Section 2.8). It would include protocols for monitoring fire conditions and adjusting training as needed (e.g., certain types of training may be disallowed under certain fire conditions), and location and management of firebreaks, fire-fighting roads, and a fire fighting water system. Units undergoing training would be briefed on requirements suitable to the conditions of the day and protocols should a fire occur (e.g., specifying how the range would shut down and how fire suppression action would be taken). With implementation of the Range Fire Management Plan, which establishes management and fire suppression and emergency response procedures, potential impacts from range-related wildfires would be less than significant. The USFWS concluded in their BO for the 2010 Final EIS that they anticipated that no additional vegetation would be lost due to wildfires igniting as a result of proposed live-fire training operations (USFWS 2010a). Therefore, there would be less than significant impacts to vegetation from operation of LFTRC Alternative 3.

**Terrestrial Conservation Areas.** Impacts to terrestrial conservation areas from the operation of the HG Range at Andersen South were discussed in Section 5.1.8.2. As Andersen South does not contain any terrestrial conservation areas, there would be no impacts.

Modeled noise levels greater than 55 dB ADNL from proposed live-fire range operations would overlie approximately 2,993 acres (1,211 ha) of Overlay Refuge lands on the NAVMAG (Table 5.3.8-4 and Figure 5.3.8-2). Overlay Refuge lands were established for the purpose of conserving and protecting ESA-listed species and other native flora and fauna, maintaining native ecosystems, and the conserving native biological diversity, recognizing that the primary purpose of lands within the Overlay Refuge is to support the national defense missions of the Navy and Air Force.

Although there would be an increase in noise associated with LFTRC activities, the proposed noise-generating activities would not result in a loss of the conservation function of Overlay Refuge lands and support the national defense missions of the Navy and Air Force at the NAVMAG. Therefore, there would be less than significant impacts to terrestrial conservation areas with implementation of Alternative 3.

Wildlife - Native Species. Operational impacts to native wildlife would include an increase in noise and lighting. These potential impacts were evaluated in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.2.2: Central, page 10-129) for a similar proposed action, and were found to be not significant. With implementation of BMPs (see previous discussion of construction impacts under Vegetation), including ongoing implementation of standard DON and commercial biosecurity protocols (e.g., Port of Guam, A.B. Won Pat International Airport) regarding detection and management of non-native species, invasive species outreach and education, applicable elements of the SIP, and 1-year post-construction monitoring to evaluate effectiveness of HACCP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of the proposed LFTRC under Alternative 3 is considered unlikely.

The DON recognizes the USFWS’ ongoing concern regarding potential spread of the brown treesnake. The DON will consult with USFWS under ESA section 7 to determine if additional brown treesnake interdiction measures are warranted and applicable. In addition, lighting associated with the range and support areas would be hooded or shielded to the maximum extent practicable to prevent unnecessary light beyond operational areas. Therefore, there would be less than significant impacts to native wildlife with operation of the proposed LFTRC under Alternative 3.

Special-Status Species: Federal ESA-Listed and Proposed Species

MARIANA FRUIT BAT. The assessment of noise levels associated with the proposed HG Range at Andersen South was previously discussed in Section 5.1.8.2. There would be no impacts to Mariana fruit bats from noise associated with operation of the HG Range.

For those species of fruit bats that have been tested for hearing sensitivity, their audiograms are very similar to those of humans, with similar upper and lower frequency limits and hearing threshold levels (Calford et al. 1995; Koay et al. 1998; Heffner et al. 2006). Therefore, it is likely that noise from live-fire operations at the proposed ranges would be heard by fruit bats as it would be heard by humans.

The USFWS established 60 dB and 93 dB as two thresholds of biological significance based on their review of impacts of noise to wildlife. Noise levels above 60 dB have been found to affect acoustic communication, breeding biology, survival of young, and non-auditory bird and mammal physiology. Noise levels above 93 dB may temporarily or permanently affect hearing (USFWS 2010a). No species would be exposed to noise levels of 93 dB or greater under the proposed action. While noise levels may approach 93 dB in the immediate vicinity of the firing of an individual weapon, fruit bats or other wildlife species would not be in proximity to the live-fire event given the location and nature of weapons firing within a developed range area.

Note: Species observations are historical sightings over multiple years and multiple surveys and do not represent the current population status or distribution of species within the depicted area.
Responses to noise can vary among individuals as a result of habituation where after a period of exposure to a stimulus, an animal stops responding to the stimulus. In general, a species can often habituate to human-generated noise when the noise is not followed by an adverse impact. Even when a species appears to be habituated to a noise, the noise may produce a metabolic or stress response (increased heart rate results in increased energy expenditure) though the response may or may not lead to changes in overall energy balance. Anthropogenic noise disturbance is known to alter animal behavioral patterns and lead to population declines (Barber et al. 2011; Francis and Barber 2013; McGregor et al. 2013).

In addition to noise level, the frequency and regularity of the noise also affect species sensitivity. That is, different types of noise sources will produce different effects on different species. Noise from aircraft overflights may not produce the same response from a wildlife species as noise from a land-based noise source such as a vehicle, chainsaw, or gun shot. Wildlife species often do not react only to a noise source but more importantly to the visual component associated with that noise source. Nesting birds will react to a noise source by tilting their head, becoming alert, etc. but often do not leave the nest or perch until there is a visual connection with the noise source. For example, birds may not react to just the sound of a chainsaw, but when that sound is coupled with a human walking near the bird, the bird will flush. This is also shown in reactions by various species to aircraft overflights (airplanes and helicopters). An overflight with just a sound component does not elicit a strong response, but if an animal hears and then sees the aircraft, the bird will more likely flush and move away (Manci et al. 1988; USFWS 1992; Krausman et al. 1993; Bowles 1995). In other words, human intrusions near roost sites, nests, foraging areas, etc. (e.g., timber harvesting, hiking, hunting) are readily detectable and substantial (USFS 1992).

Species that are commonly hunted often demonstrate behavioral (e.g., flushing, startle response) or physiological responses (e.g., increased heart rates, increased respiration rates) to gunshot sounds (Larkin et al. 1996). Knight et al. (1987) found that American crows nesting in urban areas were less wary of people than American crows nesting in rural habitat and attributed the difference to the hunting of rural crows. Barron et al. (2012) found that American crows avoided areas with live-fire exercises in a similar fashion and suggested that species hunted by humans will be more adversely affected by human activity, including military training (e.g., live-fire training) than species that are not hunted.

As stated by Morton and Wiles (2002), “Poaching is a particularly insidious activity because not only does it impact fruit bats through mortality, it reinforces behavioral avoidance of humans. Consequently, roosting or foraging fruit bats that might not otherwise be disturbed by some human activities ... may become unduly sensitized to them because of illegal hunting.” Based on observations on Guam and Rota, fruit bats have abandoned areas where hunting has occurred and did not return even though no further hunting or gunshots occurred within the area for months after (Janeke 2006; AAFB 2008b; USFWS 2009a; Mildenstein and Mills 2013). In addition, anecdotal evidence from numerous individuals who have conducted fruit bat research on Guam and the CNMI for many years indicate that fruit bats do avoid areas that have been previously subjected to hunting and also areas that experience live-fire activities (G. Wiles, Washington Department of Fish and Wildlife, personal communication, 2014; T. Mildenstein, University of Montana, personal communication, 2014; D. Janeke, HDR, Inc., personal communication, 2014; N. Johnson, Marianas Conservation Unlimited, personal communication, 2014). For example, during fruit bat monitoring at AAFB near the CATM range as part of a larger study monitoring the effects of aircraft overflights on fruit bats and crows (JRM et al. 2012b), N. Johnson observed flying fruit bats avoid the CATM range by 300-400 m when live-fire operations were being conducted (N. Johnson, Marianas Conservation Unlimited, personal communication, 2014).
However, a species can also habituate to human-generated noise when the noise is not followed by an adverse impact. While fruit bats may avoid an area subjected to hunting and the associated gun shots, fruit bats, like most wildlife species, will also learn that if a disturbance or sound does not produce an adverse effect (e.g., mortality), then they can habituate to that disturbance or sound and will not show an adverse reaction (e.g., flying away, avoiding the area) (Boyle and Samson 1985; Francis and Barber 2013).

Most of the effects of noise are mild enough that they may never be detectable as variables of change in population size or population growth against the background of normal variation (Bowles 1995). Other environmental variables (e.g., predators, weather, changing prey base, ground-based disturbance) may influence reproductive success and confound the ability to identify the ultimate factor in limiting productivity of a certain species, area, or region (Smith et al. 1988).

Based on identified recovery habitat for the Mariana fruit bat (USFWS 2010b), noise levels of 60 dB ADNL and greater would overlie 1,534 acres (621 ha) of recovery habitat in the vicinity of Alternative 3 (Table 5.3.8-5).

Given the ongoing poaching of fruit bats on Guam, it is likely that those fruit bats that currently occur on Guam will avoid areas of live-fire training as they may have experienced a poaching event. While there is the potential for eventual habituation by fruit bats to LFTRC live-fire activities, fruit bats are expected to initially avoid areas of live-fire training activities. Therefore, fruit bats may temporarily avoid approximately 1,534 acres (621 ha) of recovery habitat due to proposed live-fire range operations. However, proposed live-fire operations at the LFTRC are not continuous and would occur between 7:00 a.m. and 7:00 p.m. for 39 weeks per year, and night operations (estimated to occur 2 nights per week over 39 weeks per year) would occur between 7:00 p.m. and 10:00 p.m. or 6:00 a.m. and 7:00 a.m. In addition, live-fire operations would not physically impact recovery habitat. This temporary avoidance of recovery habitat on Guam would not preclude the recovery or survival of the fruit bat, and it would not substantially reduce the total number of fruit bats that the island can support.

With implementation of BMPs (see previous discussion of construction impacts under Vegetation), including ongoing implementation of standard DON and commercial biosecurity protocols (e.g., Port of Guam, A.B. Won Pat International Airport) regarding detection and management of non-native species, invasive species outreach and education, applicable elements of the SIP, and 1-year post-construction monitoring to evaluate effectiveness of HACCP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of Alternative 3 is considered unlikely. Therefore, there would be less than significant impacts to the Mariana fruit bat with implementation of proposed operational activities associated with Alternative 3.

MARIANA CROW, GUAM RAIL, AND GUAM MICRONESIAN KINGFISHER. These species are extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of these species is reasonably certain to occur and the species are likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of these species, nor successful suppression
of the brown treesnake to a level which would support re-introduction. Until the crow, rail, and kingfisher are successfully re-introduced and then have the potential to be exposed to operational activities under Alternative 3, there would be no impact to these species. If the species are reintroduced and exposed to LFTRC operational activities under Alternative 3, they may be disturbed.

**Mariana Swiftlet.** Based on surveys conducted for this SEIS, swiftlets were observed within the vicinity of the proposed ranges or within the modeled noise contours associated with the proposed ranges under Alternative 3 (see Figure 5.3.8-2). Swiftlets would continue to forage within the extensive foraging habitat to the north, west, and east of the proposed range areas, and areas in the vicinity of the nest/roost caves on NAVMAG and the drainages of the Mahlac, Maagas, and Talofofo rivers (see Figures 5.2.8-1 and 5.2.8-3). The proposed range operations would not impact regional insect populations that are the prey base for the swiftlet. In addition, swiftlets are generally more actively foraging in the early morning and late evenings before and after proposed range operations. As swiftlets do not have a history of being hunted, they would not have the same aversion to gunfire that Mariana fruit bats have and, therefore, may not avoid areas of live-fire range operations. Proposed range operations and associated noise would not impact the swiftlet nesting/roosting caves approximately 1 mile (1.6 km) to the east of the proposed ranges, and the nest caves would not be within the modeled noise contours associated with the proposed ranges. Therefore, given the extensive remaining foraging habitat within the surrounding areas that would still be available for foraging, and that swiftlets would still forage in the mornings and evenings before and after range operations, there would be less than significant impacts to the Mariana swiftlet due to proposed range operations under Alternative 3.

**Mariana Common Moorhen.** The modeled 55 dB ADNL noise contour overlies the northern portion of Fena Valley Reservoir, an important nesting area for moorhens on Guam. Given the low modeled noise level that may occur within the northern portion of the reservoir (i.e., 55 dB ADNL is approximately equal to ambient noise levels; see Section 3.4, Noise), there would be less than significant impacts to Mariana common moorhens with implementation of the proposed range operations under Alternative 3.

**Mariana Eight-Spot Butterfly.** Some species of tropical butterflies have well-developed ears on their wings and can detect sounds at the same frequencies that humans can hear. It is hypothesized that the butterflies are listening to the flight sounds or foraging calls of predatory birds (Lane *et al.* 2008; Yack 2012). Given the low numbers of forest birds currently on Guam due to the brown treesnake, masking of the flight sounds or foraging calls of predatory birds due to noise from proposed construction activities would not make eight-spot butterflies more susceptible to predation.

Fire potential would increase due to proposed live-fire range operations. Fire can result in direct effects to vegetation by increasing erosion, allowing for the establishment of non-native species, and altering wildlife habitat by reducing food resources, breeding habitat, and shelter. Native plants and their habitats on Guam are adapted to a humid, tropical climate and are not adapted to a fire driven ecosystem (USFWS 2008a).

As a BMP and in accordance with range safety protocols, a Range Fire Management Plan would be prepared, based on the DON’s Wildland Fire Management Plan (Nelson 2008) (see Section 2.8). It would include protocols for monitoring fire conditions and adjusting training as needed (e.g., certain types of training may be disallowed under certain fire conditions), and location and management of firebreaks, fire-fighting roads, and a fire fighting water system. Units undergoing training would be briefed on requirements suitable to the conditions of the day and protocols should a fire occur (e.g., specifying how the range would shut down and how fire suppression action would be taken). With implementation of the Range Fire Management Plan, which establishes management and fire suppression and emergency
response procedures, potential impacts from range-related wildfires would be less than significant. The USFWS concluded in their BO for the 2010 Final EIS that they anticipated that no additional vegetation would be lost due to wildfires igniting as a result of proposed training operations (USFWS 2010a). Therefore, as operation of the range would not remove additional vegetation (e.g., host plants), there would be less than significant impacts to the Mariana eight-spot butterfly with implementation of proposed range operations under Alternative 3.

**SERIANTHES Tree.** *Serianthes* does not occur within the Alternative 3 action area. Although fire potential could increase due to proposed live-fire range operations, with implementation of the proposed Range Fire Management Plan and procedures (see Vegetation above, and Section 2.8), potential impacts from range-related wildfires on *Serianthes* would be less than significant. Therefore, there would be less than significant impacts to *Serianthes* or recovery habitat due to proposed range operations under Alternative 3.

**TABERNAEMONTANA ROTENSI S AND C YCAS MICRONESICA.** Although fire potential could increase due to proposed live-fire range operations, with implementation of the proposed Range Fire Management Plan and procedures (see Vegetation above, and Section 2.8), potential impacts from range-related wildfires on *T. rotensis* and *C. micronesica* would be less than significant. There would be no other impacts to *T. rotensis* and *C. micronesica* with implementation of the proposed range operations associated with Alternative 3.

**Special-Status Species: Guam-Listed and SOGCN**

**PACIFIC SLENDER-TOED GECKO.** Although fire potential could increase due to proposed live-fire range operations, with implementation of the proposed Range Fire Management Plan and procedures (see Vegetation above, and Section 2.8), potential impacts from range-related wildfires on the Pacific slender-toed gecko would be less than significant. There would be no other impacts to the Pacific slender-toed gecko with implementation of the proposed range operations associated with Alternative 3.

**MERRILLIODENDRON MEGACARPUM.** Although fire potential could increase due to proposed live-fire range operations, with implementation of the proposed Range Fire Management Plan and procedures (see Vegetation above, and Section 2.8), potential impacts from range-related wildfires on *M. megacarpum* would be less than significant. There would be no other impacts to *M. megacarpum* with implementation of the proposed range operations associated with Alternative 3.

### 5.3.9 Marine Biological Resources

#### 5.3.9.1 Affected Environment

The Alternative 3 proposed project area is entirely inland, with no marine in-water or coastal components. Therefore, there is no marine biological resources affected environment for Alternative 3.

#### 5.3.9.2 Environmental Consequences

There are no in-water construction, dredging, or training activities and/or land-based construction activities proposed under Alternative 3 that would directly or indirectly affect the marine environment. Therefore, no direct or indirect impacts are expected.

Scoping comments for this SEIS noted concern regarding the possibility that contamination could migrate from the ranges through stormwater runoff. However, as discussed in Section 5.3.2, Water Resources, there would be no impacts to nearshore waters through implementation of surface water protection measures (i.e., compliance with Construction General Permit requirements and implementation of BMPs
during construction and implementation of LID features in accordance with the DoD UFC LID [UFC 3-210-10] and Section 438 of the EISA, range maintenance BMPs, and pollution prevention plans during operations).

5.3.10 Cultural Resources

5.3.10.1 Affected Environment

The following discussion summarizes previous cultural resources studies, known historic properties, and other cultural resources within PDIA and PIIA associated with Alternative 3. The Alternative 3 area, also known as NAVMAG (North/South), is situated in the south-central portion of Guam almost entirely within NAVMAG. As early as December 1944, miles of roads and magazines were constructed at NAVMAG and the area was commissioned on February 22, 1945 (Mason Architects and Weitze Research 2009). During a limited expansion in the Korean conflict of the early 1950s, most of the present main administration buildings and many of the magazines were designed and built as part of the permanent base development program for Guam.

The affected environment for cultural resources associated with Alternative 3 is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 12: Cultural Resources, Section 12.1.5.1: Naval Munitions Site, pages 12-33 to 12-38). This description of the affected environment is updated here with new information from recent archaeological and architectural investigations conducted for this SEIS and other projects. To determine whether site information is from previous investigations (such as the 2010 Final EIS or other cultural resource studies) or prepared during in-fill studies conducted for this SEIS, refer to dates in the reference column in each table for the archaeological sites. Certain information about built properties (such as date and function) was derived from iNFADS.

Portions of the Alternative 3 PDIA and PIIA were surveyed for the presence of cultural resources for the original proposed action (2010 Final EIS). Those and other previous investigations in the area included intensive archaeological surveys (Tuggle 1993; Hunter-Anderson 1994; Craib and Nees 1998; Henry et al. 1999; Allen et al. 2002; Hunter-Anderson and Moore 2002; Dixon et al. 2004; Welch 2010), architectural inventories (Mason Architects and Weitze Research 2010; Welch 2010), and potential TCP studies (Griffin et al. 2010). Additional investigations conducted for this SEIS included intensive cultural resource inventories conducted for the PDIA and reconnaissance inventories in the PIIA for this SEIS (Dixon et al. 2015a, 2015b). Note that due to changes in Alternative 3 as a result of the SEIS planning process, 48 acres (19.4 ha) within the PDIA and 184.19 acres (74.5 ha) in the potential indirect impact area were added after the surveys were conducted. These 232.2 acres (94 ha) were examined through historic materials, aerials, and a comparison with adjacent areas to assess impacts to cultural resources. Collectively, these investigations provide the comprehensive inventory of cultural resources for Alternative 3.

As described in Section 5.1.10.1, the HG Range would be located at Andersen South under all LFTRC alternatives. This area was previously surveyed at an intensive level (Welch 2010; Dixon et al. 2011a).
During October through December 2014, the DON consulted with the parties to the 2011 PA and the public on the Draft TRRA. Consistent with Stipulation V.C of the 2011 PA, the TRRA provided planning level information on potential direct and indirect effects to historic properties within areas that may be selected in the Navy’s ROD for the live-fire training range complex. The Draft TRRA included information on the locations, orientations, and designs of each proposed LFTRC location. In addition to receipt of written comments, DON cultural resources professionals conducted three consultation sessions with the parties to the PA to discuss the analysis. The DON will take all comments into account in preparing the Final TRRA, which is planned for publication shortly after this Final SEIS. Comments and considerations developed during the Draft TRRA consultation process have been incorporated in this Final SEIS and informed the Draft RMP, as required by Stipulation V.C.4 of the 2011 PA.

Cultural Resources in the Alternative 3 PDIA

Alternative 3 would involve the construction of individual ranges, support buildings, a munitions magazine relocation area, and access roads. This construction area comprises the PDIA. Table 5.3.10-1 lists 15 known archaeological sites located within the Alternative 3 PDIA within the NAVMAG. Eleven sites, including sites with latte sets, rockshelters, WWII military sites, and artifact scatters, are eligible for listing in the NRHP. Two sites, consisting of an historic artifact scatter, and a latte site have not been evaluated for listing in the NRHP. Two historic WWII sites are not considered eligible for inclusion in the NRHP. Should this alternative be selected, final assessments would be determined consistent with the procedures outlined in the 2011 PA.

No historic properties have been identified in the PDIA of the proposed HG Range at Andersen South.

** Legend:** GHPI = Guam Historic Properties Inventory; NRHP = National Register of Historic Places; NA = not applicable; NRHP criterion D = eligible for potential to yield information important in prehistory or history.

**Notes:**

1. Not all sites recorded within the project areas have received official GHPI numbers, although they have been documented as part of previous surveys.
2. Sites are in both the PDIA and the PIIA.
5. Eligibility of this site has not been fully determined. However, for the purpose of this analysis, it is assumed eligible.
Table 5.3.10-2 lists the 24 known structures and buildings within the Alternative 3 PDIA. All of these structures and buildings are covered under the 2006 Program Comment for World War II and Cold War Era Ammunitions Storage Facilities (ACHP 2006).

*Note: Information on type, number, and date of construction from iNFADS.*

One potential TCP, Bona Springs, is located within the PDIA for Alternative 3.

**Cultural Resources in the Alternative 3 PIIA**

The PIIA comprises within the SDZs for the LFTRC and HG ranges and associated areas potentially affected by increases in noise. It includes no locations of potential direct impact due to construction. Table 5.3.10-3 summarizes the 218 known archaeological sites located within the Alternative 3 PIIA. There are 210 NRHP-eligible sites, including artifact scatters, *latte* sites, rockshelters, and historic military features. Three sites have not been evaluated for listing in the NRHP. The remaining five sites are not eligible for listing in the NRHP. Should this alternative be selected, final assessments would be determined consistent with the procedures outlined in the 2011 PA.

**Legend:** NRHP = National Register of Historic Places; NA = not applicable; NRHP criterion C = eligible because they embody the distinctive characteristics of a type, period, or method of construction, represent the work of a master, possess high artistic value or represent a significant and distinguishable entity whose components may lack individual distinction, criterion D = eligible for potential to yield information important in prehistory or history.

**Note:** ** Revised to match Guam GHPI forms dated May 28, 2014.

^ Eligibility of this site has not been fully determined. However, for the purpose of this analysis, it is assumed eligible.
There are 72 architectural properties, constructed between 1944 and 1997, located within the PIIA for Alternative 3 (Table 5.3.10-4). These buildings and structures are primarily associated with WWII and Cold War-era ammunition storage and support facilities. Fifty-seven of the structures are ammunition storage facilities covered under the Program Comment for World War II and Cold War Era Ammunition Storage Facilities (ACHP 2006; see Chapter 3.10.3 for more information on the Program Comment). Eleven buildings and structures greater than 50 years in age have not been evaluated. Four structures are less than 50 years old and do not meet the exceptional significance threshold required under NRHP Criteria Consideration G. Should this alternative be selected, final assessments would be determined consistent with the procedures in the 2011 PA.

Six potential TCPs have been identified in the PIIA for this alternative. They include Bona Springs (which is also within the PDIA), Almagosa Springs, Dobo Springs, Almagosa Mountain, Alifan peak, and a high density area of latte sites (Griffin et al. 2010).
Environmental Consequences

Construction

Construction activities associated with Alternative 3 have the potential to adversely affect historic properties and impact culturally important natural resources. Final determinations of effect would follow the procedures outlined in the 2011 PA. Following is a discussion of potential direct and indirect adverse effects to historic properties and impacts to culturally important natural resources.

Construction of the ranges, support facilities, relocated magazine, and utilities would occur in the NAVMAG (see Figure 2.5-4). Given the substantial development anticipated in the PDIA, it is assumed for purposes of this analysis that 100% of the PDIA would be disturbed. Nevertheless, design alternatives to avoid and minimize adverse effects would be considered, consistent with procedures in the 2011 PA. No construction would occur in the PIIA. Excavation and soil removal associated with the construction of Alternative 3 could adversely affect 11 known historic properties, including Pre-Contact artifact scatters, sites containing latte components, rockshelters, and WWII military sites (see Table 5.3.10-1). Construction could also affect two unevaluated sites and one potential TCP (Bona Springs). Eight of the historic properties and the two unevaluated sites are located in both the PDIA and the PIIA. Direct impacts to these sites would only occur to the portion within the PDIA. Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the 48 acres (19.4 ha) of unsurveyed areas within the PDIA. If this alternative were selected, final assessments would be determined consistent with the procedures in the 2011 PA.

Construction associated with Alternative 3 may also require the demolition of 24 architectural properties (see Table 5.3.10-2). All of the buildings and structures are covered under the Program Comment for World War II and Cold War Era (1939-1974) Ammunition Storage Facilities (ACHP 2006), which resolves NHPA Section 106 requirements for demolition of these buildings.

Construction activities associated with Alternative 3 have the potential to directly impact culturally important natural resources. The project would require the removal of limestone forest and savanna where culturally important natural resources may be located. The 2011 PA contains measures for coordinating with the SHPO and concurring parties to contact traditional natural healers, herbal practitioners and traditional artisans regarding identification and disposition of these important resources prior to construction (see 2010 Final EIS, Volume 2: 2-10; Volume 9, Appendix G, Chapter 4).

No historic properties or culturally important natural resources are anticipated in conjunction with utility upgrades that would be associated with Alternative 3. The modification or replacement of existing overhead electrical utilities under Alternative 3 would not affect any known cultural resources. There are no known NRHP-eligible properties located in areas planned for water or wastewater upgrades to support Alternative 3.

There are no historic properties located in the PDIA or PIIA for the proposed HG Range at Andersen South. Therefore, no adverse effects to historic properties are anticipated due to construction of the HG Range.

Operation

Operations associated with Alternative 3 could cause indirect adverse effects to historic properties as discussed below. Final determinations of effect would follow the procedures in the 2011 PA. Following is a discussion of potential adverse effects of operations associated with Alternative 3.
The potential for direct effects within the SDZ would be limited to the risk of strikes from stray rounds during Alternative 3 operations. The risk of such effects occurring is extremely low. The range would be designed to contain live fire inside the range itself to minimize the probability of rounds landing in the SDZ. Additionally, if a stray round were to escape the range, the chance of it hitting a historic property is remote, given the size of the SDZ and dispersal of historic properties. For these reasons, the potential for direct adverse effects as a result of range operations is *de minimis*.

Indirect adverse effects to NRHP-eligible archaeological sites from the operation of Alternative 3 could result from changes affecting site integrity. For many types of archaeological sites (e.g., ceramic scatters, rock alignments), auditory impacts associated with live-fire operations would not affect characteristics that qualify them for the NRHP. An increase in noise associated with live-fire operations may adversely affect historic properties for which solitude, quiet, or contemplation contribute to or define their significance, such as TCPs.

Under Alternative 3, small arms live-fire noise would be audible near 60 NRHP-eligible sites and two potential TCPs (Bona Springs and Alifan peak) that are located within the expanded noise contours (Table 5.3.10-5). Average noise levels during range operations are projected to increase from current levels of approximately 45 dB ADNL to between 65 dB to 85 dB ADNL (see Section 5.3.4, Noise). Thirty-five of the sites are Pre-Contact or historic artifact scatters, rockshelters/caves, historic military features, or other historic remains, while 25 sites contain *latte* components. Auditory impacts associated with range operations would not adversely affect the integrity of the NRHP-eligible artifact scatters, historic military features, or other historic remains. Changes to the setting of the 25 NRHP-eligible sites with *latte* components could be adverse. There may also be an effect to two potential TCPs. Final determinations of effect would follow the procedures in the 2011 PA.

**Table 5.3.10-5. Summary of Archaeological Sites and Potential TCPs Potentially Affected by Noise**

</tbody>
</table>

*Legend:* NRHP = National Register of Historic Places; NRHP criterion D = eligible for potential to yield information important in prehistory or history.

**Note:** **Revised to match Guam GHPI forms dated May 28, 2014.

^ Eligibility of this site has not been fully determined. However, for the purpose of this analysis, it is assumed eligible.

Similar to certain types of archaeological sites, noise associated with range operations is not likely to adversely affect the integrity of ammunition storage support facilities. Therefore, no indirect effects are anticipated to buildings and structures from changes in noise levels.
No indirect adverse effects from visual intrusions associated with Alternative 3 are anticipated, as the ranges are within an existing military operations area and the action would not involve a change in visual setting.

Access to all sites within the PIIA would be restricted during range operations; however, most of these sites are located within areas that currently have limited access due to operations at NAVMAG or their remote locations. Members of the public have requested to visit Almagosa Springs and other areas of NAVMAG in the past and there is a process to access certain areas. Therefore, indirect impacts could result from additional restrictions on access to five potential TCPs: Bona Springs (which is also within the PDIA), Almagosa Springs, Dobo Springs, Almagosa Mountain, and a high density area of latte sites. The 2011 PA requires development of plans for regular public access to historic properties for DoD-controlled lands on Guam, subject to considerations including but not limited to public interest, public safety concerns and protocols, installation security, and emergency situations.

**Summary of Impacts and Potential Mitigation Measures**

Implementation of Alternative 3 could cause direct, adverse effects to 11 known NRHP-eligible archaeological sites. Potential indirect adverse effects could occur to 25 NRHP-eligible archaeological sites with latte components. Direct effects could occur to two unevaluated sites and one potential TCP, and indirect effects could occur to two potential TCPs. Five potential TCPs could also be indirectly affected due to restricted public access. In addition, culturally important natural resources could be directly impacted due to removal of limestone forest and savanna vegetation. If this alternative were selected, final assessments would be determined consistent with the procedures identified in the 2011 PA.

Adverse effects that could occur from construction and operation under this alternative would be less than under other alternatives (the greatest effects from construction would occur under Alternative 5, whereas the greatest effects from operation would occur under Alternative 5). See Table 5.7-1 for a comparison of cultural resources impacts and potential mitigation measures for each LFTRC alternative.

The 2011 PA, as discussed in Section 3.1.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. Broadly, the 2011 PA includes processes to share information, consider views of the public, and develop mitigation measures when historic properties are adversely affected. The 2011 PA provides measures for mitigating adverse effects to NRHP-eligible or listed archaeological sites, consulting on new projects and initiating additional identification efforts, and resolving impacts due to loss of access to potential TCPs or culturally important natural resources.

More specifically, the 2011 PA established a process for the review and analysis of potential effects to historic properties and other cultural resources for all alternative LFTRC locations. During October through December 2014, the DON consulted with the parties to the PA and the public on the TRRA, which provided information about cultural resources potentially affected by the LFTRC alternatives carried forward in the SEIS, consistent with PA Stipulation V.C. The TRRA provides information on potential adverse effects resulting from the construction and operation of the LFTRC alternative to support consultation with the PA parties and the public. The DON will take all comments into account before reaching a final decision. For any alternative selected in the ROD, the 2011 PA stipulates that a RMP will be prepared to address effects from the construction and operation of the ranges. The RMP, developed in consultation with the consulting parties, will stipulate measures to avoid, minimize, and mitigate adverse effects to historic properties.

To the degree possible, direct and indirect impacts to historic properties and other resources of cultural importance would be avoided or minimized during the planning process. Consultation under the 2011 PA
would address potential adverse effects and alternatives to avoid adverse effects. Refer to Section 3.10 for more information on definitions and procedures. If avoidance is not possible, Table 5.3.10-6 presents potential mitigation measures to resolve adverse effects to historic properties and reduce direct and indirect, short- and long-term impacts to cultural resources resulting from the implementation of Alternative 3. With the implementation of these measures and processes as outlined in the 2011 PA, it is expected that impacts could be reduced to a level below significance.

**Table 5.3.10-6. Potential Mitigation Measures for Alternative 3 for Adverse Effects (NHPA) and Impacts to Other Cultural Resources (NEPA)**

### 5.3.11 Visual Resources

#### 5.3.11.1 Affected Environment

The 2010 Final EIS describes the proposed activities to occur at NAVMAG (Volume 2, Chapter 2: Proposed Action-Training Functions, Section 2.3.1.3: Non-Firing General Military Skills Training Facilities, page 2-49). Although Alternative 3 differs from the 2010 Final EIS activities at NAVMAG, the potentially affected visual environment and the visual resources themselves would remain the same. A list and description of visual resources at the NAVMAG are provided in the 2010 Final EIS (Volume 2, Chapter 13: Visual Resources, Section 13.1.4.1: Naval Munitions Site, pages 13-54 to 13-57). See Section 4.3.11 of this SEIS for a summary of the visual resources at NAVMAG.

#### 5.3.11.2 Environmental Consequences

Unlike Alternative 2 described in Section 5.2.11 above, Alternative 3 would involve the construction of up to four live-fire ranges and a range maintenance building 3 miles (5 km) north of Mount Lamlam and 4 miles (6 km) north of the publicly accessible Jumullong Manglo Overlook. The Alternative 3 facilities would possibly be visible from these public areas, as well as from the trails leading up to them.

#### Construction

During construction, activities and equipment would temporarily cause view obstructions where recognized views currently exist. These direct visual impacts during the construction phase would be short-term and would be less than significant.
Operation

The public viewing areas would be separated from the Alternative 3 facilities by a distance of 3 to 4 miles (5 to 6 km) with a substantial amount of topography in between. However, the elevation of both Mount Lamlam (the highest point on Guam and a National Natural Landmark) and Jumullong Manglo Overlook could present views of Alternative 3 structures, 3 miles (5 km) of new roadways, areas of removed vegetation, cut/fill features, and earthen berms. The direct long-term impact on visual resources viewable to the public from Mount Lamlam, Jumullong Manglo Overlook, and other vista points where the interior of NAVMAG would be altered, would be significant, given the large amounts of vegetated landscape and components of the scenic vista that would be altered and acquire a more developed appearance as a result. Potential mitigation measures to reduce this impact to less than significant are the following:

- To maintain the existing visual appearance, land clearing and grading should be minimized to the extent possible on lands proposed for range uses.
- Minimize impact by using native flora to create a natural-appearing “screen” around the cleared range areas, outside of the firebreaks/perimeter roads.

Alternative 3 would have a greater impact to visual resources than Alternatives 1, 2, and 5 because of the potential long-term ability to see the new structures from public viewing areas. Alternative 3 would also have a greater impact than Alternative 4, because more of the new roadway and ordinance magazines may be visible.

The level of significance of visual resource impacts resulting from implementation of Alternative 3 would be the same as those of Alternatives 1 and 4, and greater than the impacts of Alternatives 2 and 5.

5.3.12 Ground Transportation

5.3.12.1 Affected Environment

The affected environment for ground transportation resources Alternative 3 includes transportation facilities internal to the site (range roadways and intersections). This section discusses existing conditions and assesses how construction and operations of Alternative 3 would potentially affect transportation conditions for roadways and intersections internal to the site. Impacts to off-base (external) roadways and intersections are summarized in Section 6.1 of this SEIS.

5.3.12.2 Environmental Consequences

Construction

Potential construction impacts to ground transportation under Alternative 3 would be similar to those discussed in Section 4.1.12.2 for Alternative A. Potential direct and indirect impacts to ground transportation resources from construction would be minimized with implementation of appropriate work zone traffic management strategies and BMPs. Therefore, there would be less than significant direct short-term impacts to on-base (internal) roadways.

Operation

Proposed access to Alternative 3 would be from the existing NAVMAG Main Gate located on Route 5. Existing roadways would be used wherever possible. However, this alternative requires the construction of an access road to allow all-weather operations, as well as a total of approximately 3.0 miles (5.0 km) of internal roadways, which would be required to support LFTRC operations. Potential operational impacts for Alternative 3 would be the same as those described in Section 5.1.12.2 for Alternative 1, and there would be no direct, long-term significant impacts to internal (range) roadway segments or intersections.
5.3.13 Marine Transportation

5.3.13.1 Affected Environment

The Alternative 3 and SDZ would not extend over open waters used by vessels. Thus, there would be no marine transportation in the proposed area.

5.3.13.2 Environmental Consequences

Implementation of Alternative 3 would not impact open waters used by vessels. Therefore, it is expected that there would be no impact to marine transportation due to the construction and operation of Alternative 3.

5.3.14 Utilities

5.3.14.1 Affected Environment

Existing utilities in the vicinity of the proposed HG Range are the same as discussed in Section 5.1.14.1 for Alternative 1.

Electrical Power

The electrical utility near the Alternative 3 consists of the existing DoD local power distribution system serving the existing NAVMAG facilities. This system includes power lines and transformers. The system is 3-phase 13.8 kV service.

Potable Water

The potable water system near Alternative 3 includes the local DoD water distribution system buried underground, the DON water treatment plant, Fena Reservoir, and water transmission lines from the water treatment plant to the DoD water system. The transmission lines mainly serve Naval Base Guam Apra Harbor. However, other DoD installations and the GWA typically also receive potable water from this source.

Wastewater

The wastewater utility near Alternative 3 consists of DoD wastewater collection systems buried underground in the existing NAVMAG area.

Solid Waste

There are no solid waste facilities near Alternative 3. The existing NAVMAG area is served by JRM contractors for solid waste pickup, handling, and disposal.

Information Technology and Communications

There is existing DoD IT/COMM infrastructure near Alternative 3 consisting of buried communication lines. No commercial IT/COMM lines are within the areas of Alternative 3.

5.3.14.2 Environmental Consequences

Potential impacts to existing utilities from operation of the HG Range would be the same as discussed in Section 5.1.14.2 for Alternative 1.
Electrical Power

The proposed electrical system improvements for Alternative 3, as described in Sections 2.5.4.3 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The electrical power requirements of the LFTRC facilities would be small (50 kW). During construction, there would be direct, short-term impacts on current customers consisting of potential limited power outages during construction. Power outages would be addressed through construction phasing or the use of temporary generators where necessary, which would minimize downtime.

The direct short- and long-term impact of Alternative 3 on the electrical utility would be less than significant, both during construction and in operation.

Potable Water

The proposed water system improvements for Alternative 3, as described in Sections 2.5.4.3 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The Range Maintenance Building and the KD Rifle/KD Pistol Range Administrative Building are the only LFTRC facilities requiring water service. A fire hydrant would also be provided for filling range fire fighting vehicles and general fire protection. The long-term potable water demand of the LFTRC would be small, estimated at an average daily demand of 26,520 gallons per day (100,389 liters per day). Therefore, less than significant direct, long-term impact would occur to the current DoD system. During construction minor, short-term water service outages could occur as new water lines are connected to existing water lines. With careful planning these potential outages would be minimized.

The direct short- and long-term impact of Alternative 3 to the potable water utility would be less than significant, during both during construction and in operation.

Wastewater

The proposed wastewater collection system improvements for Alternative 3, as described in Sections 2.5.4.3 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The only LFTRC facilities requiring sewer service would be the Range Maintenance Building and the KD Rifle/KD Pistol Range Administrative Building that would have an estimated wastewater flow of 0.01 MGd (0.038 MLd). A new sewer line would be installed and tied into the existing sewer line within the NAVMAG area to serve the Range Maintenance Building. The estimated long-term wastewater demand for this facility is minimal and there would be minimal long-term, direct impact on the existing sewer collection or treatment systems. Any outages to service during construction would be kept both minimal and short-term by doing tie-in work at low flow times, providing bypass lines and pumps, and by careful planning and design of the tie-in methods.

All other LFTRC facilities, including the HG Range, would be provided with portable toilets. These toilets would require periodic emptying, with the sewage then being taken to one of the existing WWTPs for treatment. The estimated long-term sewage amount is minimal and would not directly impact the current wastewater utility.

The direct short- and long-term impact of Alternative 3 to the wastewater utility would be less than significant, both during construction and in operation.

Solid Waste

The proposed solid waste infrastructure improvements for Alternative 3, as described in Sections 2.5.4.3 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The
long-term estimated solid waste generation for LFTRC operations is small and this additional solid waste would not directly impact current waste collection, handling, or disposal operations. Suitable solid waste collection containers would be provided where required. The solid waste would be periodically collected, handled, and disposed; as currently done by JRM contractors, who would add these containers to their pickup schedule.

Short-term, direct impacts to the solid waste handling effort during the U&SI phase involving the generation of green waste and C&D waste would be the same as discussed in Section 5.1.14.2 for Alternative 1.

The direct short- and long-term impact of Alternative 3 on the solid waste utility would be less than significant, both during construction and in operation.

Information Technology and Communications

The proposed IT/COMM infrastructure improvements for Alternative 3, as described in Section 2.6, have been developed to meet the requirements for the proposed action. There is one existing DoD IT/COMM line that underlies the proposed location for the MRF Range. This line would require rerouting during construction of the MRF Range. This would cause a short-term, temporary loss of service during switchover from the existing line. With careful planning the loss of service would be minimized. New conduit duct banks that would be required for Alternative 3 include six 4-inch (10-cm) conduits to interconnect the LFTRC range facilities with the HG Range. There would also be inter-base connectivity required for DoD IT/COMM, as discussed in Section 2.6. Some of these inter-base connections in the southern part of Guam would require new rights of way.

The direct short- and long-term impact of Alternative 3 on the IT/COMM utility would be less than significant, both during construction and in operation.

5.3.15 Socioeconomics and General Services

Most issues and impacts associated with socioeconomics and general services encompass the entire proposed action (i.e., cantonment/family housing and LFTRC development, and increased population), and do not vary with site alternatives. Accordingly, the impact discussion in Section 4.1.15 of this SEIS applies for all of the LFTRC alternatives and is incorporated here by reference. Land acquisition however is unique to the LFTRC alternatives, and the amount of land to be acquired varies by alternative. Therefore, this section focuses exclusively on the socioeconomic and sociocultural issues and impacts associated with the acquisition of land under Alternative 3 (with the exception of the HG Range, which would not require land acquisition).

5.3.15.1 Affected Environment

Table 5.3.15-1 displays baseline data for land that would be acquired for Alternative C. A total of 252 acres (102 ha) of land would be acquired by the federal government. Most of the land (156 acres, 63 ha) is privately owned, including at least four of the 23 lots that would potentially be acquired. GovGuam owns 46 acres (19 ha) spread over two lots. Seventeen lots that would be acquired have unknown ownership.

Table 5.3.15-2 shows existing land use in the NAVMAG (North/South) acquisition area. Land use on the NAVMAG (North/South) parcel consists of 252 acres (102 ha) of undeveloped land. The GBSP land classification for the entire acquisition area is Agriculture. However, as described in the Land Use Section 5.3.6, no current agricultural use was identified. None of the acreage currently has a productive economic use.

With regard to the affected fiscal environment of Guam, as stated in Section 5.1.15, GovGuam collected a total of $20.1 million in property tax revenues. These revenues accrue to the GovGuam general fund.

5.3.15.2 Environmental Consequences

The DON is required to comply with federal land acquisition laws and regulations, which include the requirement to offer just compensation to the owner, to provide relocation assistance services and benefits to eligible displaced persons, to treat all owners in a fair and consistent manner, and to attempt first, in all instances, acquisition through negotiated purchase. Specific policies and procedures, including the Uniform Act, are described in detail in Section 5.1.15.2.

While the government is authorized to acquire property through its powers of eminent domain (condemnation), it has been the consistent policy of the DON to acquire real estate through negotiation with owners. Even with a negotiated sale or lease however, “friendly” condemnation may be necessary to clear problems with title. The DON would comply with all applicable laws and regulations, including the Uniform Act.

In general, assuming voluntary sale or lease of property and conformance with land acquisition laws and regulations, land acquisition impacts from both a socioeconomic and sociocultural perspective would not be considered significant. Should condemnation be necessary as a last resort, while the landowner would be made economically whole by payment of fair market value, such an occurrence could represent an adverse sociocultural impact for that individual landowner. Such instances are expected to be extremely
rare or nonexistent during implementation of this proposed action, and collectively would not represent a significant impact.

**Socioeconomic and Sociocultural Impacts**

Potential impacts associated with land acquisition could affect individual property owners, occupants, the surrounding community, and GovGuam. Economic impacts presented in this section are total impacts. They include impacts that would be generated by the proposed action both directly and indirectly. Individual owners and occupants might be impacted from an economic perspective or a sociocultural perspective. Economic impacts associated with land acquisition are those that are purely financial. Sociocultural impacts associated with land acquisition are less tangible and are based on conceptual frameworks such as social disarticulation and cultural marginalization (the deterioration of social structures, networks, or belief systems), and social and psychological marginalization, stress, and anxiety (a person’s loss of confidence in society and themselves, feelings of injustice, and reduced social status). See Appendix D, Section 5.2.2 for more detail.

**Individual Owner/Occupants**

With regard to economic impacts, if acquisition of privately-owned lots were to occur through negotiated purchase with the owners, there would be no adverse impact. As required under the Uniform Act, the purchase would take place at fair market value. Conversely, if the property was acquired through condemnation the federal government would still be required under the Uniform Act to reimburse the property owner at the fair market value. Therefore, the land acquisition would not cause an adverse economic impact to individual landowners.

With regard to sociocultural impacts, this alternative would require the acquisition of 23 separate lots, including two lots owned by GovGuam. Of the lots required, four are known to be privately owned and 17 lots have unknown ownership, so up to 21 different private parties could be affected. It is anticipated that, in all cases, a negotiated sale or lease between the federal government and a willing seller would be arranged, and there would be no adverse sociocultural impact. In the unlikely event that the land was acquired through condemnation, it is possible that the individual landowner would potentially consider the forced sale or lease of property to be an adverse impact (despite being paid fair market value).

**Community**

With regard to economic impacts, the NAVMAG (North/South) lands are undeveloped in a natural state (see Table 5.3.15-2), and no current agricultural activities or other economically productive land uses were identified. Because the land that would be acquired does not currently have an economically productive use, and the fair market value would account for the highest and best use, there would be no adverse economic impact.

With regard to sociocultural impacts, the addition of an estimated 252 acres (102 ha) of federal land on Guam would be considered by some citizens to be an adverse impact due to the current extent of federal land that is under DoD custody and control (25.9% of all land on Guam, see Section 5.1.15), which would increase to 26.1% with acquisition of the NAVMAG North/South parcel. However, because of the DON’s commitment to the concept of “net negative,” by the end of the Marine Corps relocation there would be no net increase in federal land under the custody and control of the DoD.

Five recreational sites are located in the vicinity of Alternative 3 (see Section 5.3.7). Four of the five recreational sites are located on NAVMAG and are only open to installation personnel and their guests. The remaining recreational site, Talofofo Falls Park and Hiking Trail, is accessible to the public along the
existing access road between Route 4 and the Dandan Communication Site and is not located within the land acquisition boundary. Although access to Talofafo Falls Park and Hiking Trail may be temporarily affected during construction activities along the access road, the proposed construction activities along the access road would be short-term in duration, and associated direct sociocultural impacts would be less than significant.

**Government of Guam**

The current 156 acres (63 ha) of land in Alternative 3 that are privately owned are subject to GovGuam property tax. The average per acre value for these parcels is $206,911. The total tax base for private lands is estimated to be $32.3 million ($206,911 x 156 acres). On this property, land owners pay an estimated $27,436 in property taxes to GovGuam. Acquisition of this property by the federal government would represent a loss of 0.14% of FY 2011 GovGuam property tax revenues, representing an adverse but less than significant impact.

GovGuam owns 360 acres (146 ha) of the land subject to acquisition under this alternative. At present, this land is not developed, leased or otherwise generating income for GovGuam. As such, either a sale or lease would generate a direct small beneficial economic effect (though less than significant in magnitude).

### 5.3.16 Hazardous Materials and Waste

**5.3.16.1 Affected Environment**

The current DoD ROI on Guam for hazardous materials and waste in this section includes Navy property proposed for development of a LFTRC. Navy property includes undeveloped lands located in the northwest portion of the NAVMAG site, the western perimeter of the SDZ boundary and an additional area northwest of the Fena Valley Reservoir.

**Hazardous Material and Hazardous Waste Management**

The affected environment or present conditions at NAVMAG with regards to hazardous materials and hazardous waste management would be the same as described in Section 3.16.1 of this SEIS, which provides a summary of hazardous materials, hazardous waste, toxic substances, and contaminated site information pertinent to Guam. Currently there are three hazardous waste accumulation sites (NAWMU-1, B-870, NMC-EAD, B-901 and B-740, Ordnance) and two less-than-90 day storage areas (585B U.S. Navy Lab and B-404) located at NAVMAG (NAVFAC Pacific 2013c).

**Contaminated Sites**

*Installation Restoration Program Sites*

One IRP site, Site 35 - Tear Gas Burial Site, is located along the western boundary of the NAVMAG site and is in the vicinity of an area proposed for development for a live-fire training range complex under Alternative 3 (Figure 5.3.16-1). This IRP site was determined to have no effect on proposed NAVMAG site conditions (NAVFAC 2012).

*Military Munitions Response Program*

One MMRP site, UXO 3 NAVMAG Small Arms Range, was identified in the area of NAVMAG proposed for development of this LFTRC alternative. This active site is described in detail in the 2010 Final EIS (Volume 9, Appendix G: EIS Resource Technical Appendix, Chapter 3: Hazardous Materials and Waste Resources, Section 3.5: South, Table 3.6-5: Summary of Active Hazardous Waste Sites in South Guam, page G-3-53). This MMRP site was determined to have no effect on proposed NAVMAG site conditions (NAVFAC Pacific 2010a).
Figure 5.3.16-1
Active and Restricted IRP Sites and MMRP Sites within NAVMAG (North/South) LFTRC Alternative 3

Source: NAVFAC Pacific 2013
Toxic Substances Management

Currently, portions of the area that would be affected by the proposed LFTRC development contain magazines for the storage of various munitions. Any structure constructed prior to 1978 may contain LBP, ACM and PCBs.

According to USEPA, the parcel is located in an area classified as Zone 3 for radon, indicating average indoor radon levels of less than 2 pCi/L.

5.3.16.2 Environmental Consequences

Construction

Hazardous Materials and Waste

Construction activities would result in a short-term increase in the use of hazardous materials, and generation of hazardous waste that would cease at the completion of construction activity and would be the same as described in Section 5.1.16.2 of this SEIS. Should there be a need to import off-island earthen materials, all GEPA, Department of Agriculture, and local rules and regulations would be followed. Due to the short-term nature of the construction activity and the limited amount of hazardous materials and waste that would be generated, direct or indirect impacts would be less than significant.

Contaminated Sites

No contaminated sites were identified on the subject property. Therefore, no direct or indirect impacts to contaminated sites from construction activities would occur.

Toxic Substances

Demolition and construction activities associated with this alternative would have less than significant impacts on toxic substances. The demolition of magazines may result in encountering PCBs, ACM and LBPs that were used in the older building materials. If PCBs, ACM, and/or LBPs are encountered during demolition, licensed contractors would be used for these projects to ensure that all DoD, federal, state, and local PCBs, ACM, and LBP testing, handling, and disposal protocol, procedures, and requirements are followed. Toxic substances would not be utilized for new construction. LBPs were banned by USEPA in 1978 and most uses of PCBs were banned by USEPA in 1979. Although not a banned substance, ACM would not be used to construct proposed new facilities on Guam. Because the proposed construction areas are located in a USEPA Radon Zone 3, it is unlikely that new buildings, facilities and structures would encounter radon intrusion. No direct or indirect impacts would occur and no potential mitigation measures may be required.

Operation

Hazardous Materials

Live-fire training ranges would generate a long-term increase in the release of hazardous materials from expended training materials resulting from proposed new training operations and would be similar to those described in Section 5.1.16.2 of this SEIS. However, because the training ranges and associated SDZs would be land-based, there would be no direct impacts to open waters. As described in Section 5.1.16.2, direct or indirect impacts would be less than significant.
Hazardous Waste

Operation of the live-fire training ranges would result in a long-term increase in the generation of hazardous waste and associated impacts would be the same as described in Section 5.1.16.2 of this SEIS. As described in Section 5.1.16.2, direct or indirect impacts would be less than significant.

Contaminated Sites

No contaminated sites were identified on the subject property. Therefore, no direct or indirect impacts to contaminated sites from increased Marine Corps range training activities would occur.

Toxic Substances

When assessing the transport, transfer, and future use of toxic substances associated with the development of firing ranges on Guam, no significant environmental consequences from ACM, LBP, and PCBs are anticipated. This is because LBPs were banned by the USEPA in 1978 and most uses of PCBs were banned by the USEPA in 1979. In addition, ACM and gases would not be transported or transferred as a result of these activities. Existing BMPs and SOPs (2010 Final EIS, Volume 2, Chapter 17: Hazardous Materials and Waste, Section 17.2.2 Alternative 1, Table 17.2-3: Summary of BMPs and SOPs, pages 17-141 to 17-43 and Volume 7, Chapter 2: Overview of Best Management Practices and Mitigation Measures, Section 2.1: Best Management Practices on Guam and Tinian, Table 2.1: Summary of Key Best Management Practices [Guam and Tinian], pages 2-4 to 2-23) and summarized in Chapter 2 of this SEIS would be followed to the maximum extent practicable. Adherence to applicable BMPs (e.g., erosion control, routine inspections, employee training) would reduce the likelihood and volume of accidental releases from site disturbance and enable timely implementation of cleanup measures, thereby minimizing potential impacts to the environment. Because the proposed construction areas are located in a USEPA Radon Zone 3, it is unlikely that new buildings, facilities and structures would encounter radon intrusion. Toxic substances direct or indirect impacts would be less than significant during operations.

5.3.17 Public Health and Safety

5.3.17.1 Affected Environment

Operational Safety

To protect the general public from intentional or accidental entry onto NAVMAG property, locked or manned gates are used where vehicle access is provided and a series of warning signs cautioning personnel not to enter the area are posted along the perimeter of the installation. Unauthorized personnel are not allowed on the installation at any time.

A small arms range and sniper range are present on the west-central portion of NAVMAG. In addition, an emergency demolition range is present in the central portion of NAVMAG, west of the Fena Valley Reservoir. Both of these ranges are within the SDZ footprint for Alternative 3. Activities at these ranges are conducted in accordance with SOPs to ensure the safety of both range participants as well as the general public.

The munitions operations and storage area and the emergency demolition range on NAVMAG have associated ESQD arcs that restrict the construction of inhabited buildings and other non-munitions related activities to minimize potential impacts on personnel and the general public from an explosive mishap. Explosives handling and storage is the primary function within the munitions storage area. Detonation of UXO in emergency situations is the primary function of the emergency demolition range.
Environmental Health Effects

Aviation training is limited to four helicopter landing zones at NAVMAG. Landing Zone 1 is within the proposed SDZs associated with Alternative 3 development, and is used in airborne raid-type training, along with an adjacent breacher house. The overflight of helicopters produces noise. However, this training is infrequent and occurs at locations within the installation away from populated areas, resulting in no community noise effect. In addition, a small arms range and sniper range are internal to the installation and do not present a current noise management issue.

Land demolition activities take place at the NAVMAG demolition range in the central portion of the installation (approximately 4,100 feet [1,250 m] from the closest public boundary). Although individuals exposed to these noise events may be startled if they are unaware of the source of the noise, the brevity and relative infrequency of activities does not result in noise contours extending onto adjacent public lands. Details regarding current noise conditions at NAVMAG are provided in Section 5.3.4.1.

Water Quality

The Fena Valley Reservoir, which is the primary drinking water source for the southern portion of Guam, is within the NAVMAG boundary. Water quality from the Fena Valley Reservoir and regional springs is generally high, requiring minimum treatment and chlorination for domestic use. Threats to water quality include sedimentation from accelerated erosion, eutrophication because of persistent conditions of low dissolved oxygen, and fecal material contamination from deer, feral animals, and other animals (DON 2010a). Section 5.3.2.1 provides details regarding current quality of potable water sources.

Hazardous Substances

Management practices and contingency plans for the use, handling, storage, transportation, and disposition of hazardous substances associated with NAVMAG ensure that exposure to the environment and human contact is minimized.

The IRP focuses on cleaning up releases of hazardous substances that pose risks to the general public and/or the environment. The MMRP focuses on identifying and removing MEC. U.S. Naval Activities Site 35 (Tear Gas Burial Site) is situated west of the proposed MPMG live-fire training area but does not directly affect the Alternative 3 development. Contaminants of concern at this site include polynuclear aromatic hydrocarbons. Land use controls are in place at this site. A small arms range and sniper range (MMRP Site UXO 3) are present on the west-central portion of NAVMAG. In addition, an emergency demolition range is present in the central portion of NAVMAG, west of the Fena Valley Reservoir. Activities at these ranges are conducted in accordance with SOPs to ensure the safety of range participants as well as the general public. The hazardous materials and waste section of this SEIS (see Section 5.3.16) provides additional detail for the status of IRP and MMRP sites.

Unexploded Ordnance

The presence of UXO within the Alternative 3 area is unknown. However, Guam was an active battlefield during WWII. As a result of the occupation by Japanese forces and the subsequent assault by Allied/American forces to retake the island, unexploded military munitions may still remain.

Traffic Incidents

No high crash frequency locations have been identified in the vicinity of the Alternative 3 area.
5.3.17.2 Environmental Consequences

Potential impacts on public health and safety from implementation of Alternative 3 would be similar to those discussed for Alternative 2 (see Section 5.2.17).

Operational Safety

Construction Safety

Potential impacts from construction safety would be similar to those discussed for Alternative 2. During construction activities, a health and safety program would be implemented by the construction contractors based on industry standards for accident and pollutant release prevention. Because a health and safety program would be implemented for construction activities and the general public would be excluded from entering construction areas, potential short-term construction impacts on public health and safety would not result in any greater safety risk. Therefore, no direct or indirect impact on public health and safety related to construction activities is anticipated.

Operation/Range Safety

To protect the general public from intentional or accidental entry onto live-fire training ranges, a series of warning signs cautioning unauthorized personnel not to enter the area would be posted along the perimeter of the installation as well as at the range area. Unauthorized personnel would not be allowed on the installation or range at any time.

SOPs require that before conducting training activities, the general public and non-participating personnel would be cleared from the area so that the only public health and safety issue would be if a training event exceeded the safety area boundaries. Risks to public health and safety would be reduced by confirming that the training area is clear. The Range Safety Officer would ensure that hazardous areas are clear of personnel during training activities. After a live-fire event, the participating unit would ensure that weapons are safe and clear of live rounds.

Use of established training areas and compliance with appropriate range safety procedures would reduce the potential for interaction between the general public and personnel that are training. Specific and documented procedures would be in place to ensure the general public is not endangered by training activities. Therefore, Alternative 3 would result in no direct or indirect impact on public health and safety from operations and training activities.

Explosive Safety

Ordnance used at Alternative 3 would be handled, stored, and transported in accordance with Marine Corps explosive safety directives (MCO P8020.10A, Marine Corps Ammunition Management and Explosives Safety Policy Manual), and munitions handling would be carried out by trained, qualified personnel. For the proposed LFTRC under Alternative 3, SDZs have been defined for each of the ranges to identify the areas requiring control of unauthorized access to live-fire training operations. The SDZs established for Alternative 3 reflect a “worst case scenario” for weapons use to ensure the safety of on- and off-range personnel and civilians. The proposed layout of the SDZs is provided in Chapter 2.

With implementation of appropriate range safety procedures, no direct or indirect impact on public health and safety is anticipated from Alternative 3 activities.

The munitions operations and storage area as well as the emergency demolition range on NAVMAG have associated ESQD arcs that restrict the construction of inhabited buildings and other non-munitions related activities, to minimize potential impacts on personnel and the general public from an explosive mishap.
The ESQD arcs overlay Alternative 3 firing positions and the associated SDZs. Because the ESQD arcs overlay proposed live-fire training firing positions and SDZs, a conflict between the current munitions storage and EOD range activities with the proposed live-fire training activities would occur. However, munitions magazine relocation is included in Alternative 3 to eliminate this conflict. An explosive safety review would be needed to ensure compatible development and use. In addition, SDZs for Alternative 3 activities encumber the existing breacher house, sniper range, emergency demolition range, Landing Zone 1, and a portion of the non-firing maneuver area resulting in a safety conflict between the use of these facilities/areas and the proposed live-fire training activities. Use of these facilities/areas would be prohibited when Alternative 3 is supporting live-fire training. The emergency destruction mission of the emergency demolition range would take precedence over Alternative 3 activities. As part of Alternative 3 development, munitions magazines would be relocated to eliminate both the conflict between proposed Alternative 3 live-fire training locations and existing ESQDs for current NAVMAG mission activities, as well as the conflict between SDZs and current NAVMAG facilities. No significant safety impacts (direct or indirect) would result if existing incompatible munitions magazines are relocated.

**Environmental Health Effects**

**Noise**

Potential impacts on public health and safety from Alternative 3 noise would be similar to those discussed for Alternative 2. Increases in noise emissions associated with implementation of the short-term construction phase of this alternative with identified BMPs would be less than significant. Enforcement of OSHA guidelines for hearing protection for workers would be the responsibility of the construction contractors. Noise from Alternative 3 activities (i.e., weapons firing) would be heard on adjacent lands from the range. Some adjacent lands north and west of Alternative 3 include residential uses. However, no people would be exposed to incompatible noise levels (see Section 5.3.4.2). Sound generated from Alternative 3 activities would not result in loss of hearing to nearby residents because no residences are located in incompatible areas. Based on the modeled noise for Alternative 3 activities (see Section 5.3.4), the overall direct or indirect impacts associated with noise on public health and safety would be less than significant.

**Water Quality**

Potential impacts on public health and safety from water quality concerns would be similar to those discussed for Alternative 2. Water withdrawal would likely increase. However, sustainability practices would be implemented to reduce the amount of water needed (see Section 5.3.2.2). The resulting total annual water withdrawal would be less than the sustainable yield, and monitoring of water chemistry would identify any emerging issues to ensure no harm to the water supply.

The Fena Valley Reservoir is within the NAVMAG boundary and is the primary drinking water source for the southern portion of Guam. The reservoir is located southeast of Alternative 3 and is outside established SDZs for live-fire training activities. The SDZs define the ground area needed to contain projectiles, fragments, debris, and components resulting from the firing, launching, and/or detonation of weapons. Because Alternative 3 activities would be contained within the designated SDZs, no direct or indirect impact on the Fena Valley Reservoir is anticipated.

Because measures would be taken to maintain a sustainable water supply and the Fena Valley Reservoir is outside the SDZs for Alternative 3 activities, public health and safety impacts from long-term increased demand on potable water and potential water-related illnesses would be less than significant.
Hazardous Substances

Potential safety impacts from use of hazardous substances would be similar to those discussed for Alternative 2. Implementation of this alternative would result in an increase in the use, handling, storage, transportation, and disposition of hazardous substances. These activities would be conducted in accordance with applicable hazardous material and waste regulations, and established BMPs and SOPs to ensure that the health and safety of workers and the general public is maintained. IRP and MMRP investigations and/or remediation activities, as necessary, would continue in an effort to clean up past releases of hazardous substances that pose a risk to the general public and the environment. Continued regulatory oversight and concurrence would ensure that necessary actions have been completed to ensure the safety of the general public. Because hazardous substance management and IRP/MMRP investigative/cleanup activities would be conducted in accordance with applicable regulations and established BMPs and SOPs, no direct or indirect impact on public health and safety is anticipated.

With regard to exposure to airborne toxic dust related to live-fire training activities and range maintenance, lead is the primary contaminant of concern. Very small lead particles can become airborne if wind, foot traffic, or maintenance activities disturb lead-contaminated soil. Firing ranges would be designed and constructed so that participating personnel are not exposed to airborne contaminants above permissible limits. The nearest residential population is located approximately 0.5 mile (0.8 km) to the north and emissions migrating off range would likely be much lower than on-site. Analysis of firing range emissions presented in the 2010 Final EIS (Volume 2, Chapter 5: Air Quality, Section: 5.2.7: Summary of Impacts, Table 5.2-8, page 5-36) indicated that operations emissions from firing range components would be well below significance criteria. Because range maintenance procedures ensure that participating personnel are not exposed to airborne contaminants above permissible limits and analysis of firing range emissions are below significance criteria, a less than significant direct or indirect impact on public health and safety from firing range activities is anticipated.

Unexploded Ordnance

Potential impacts from UXO would be similar to those discussed for Alternative 2. Excavation for building foundations, roads, underground utilities, and other infrastructure could encounter unexploded military munitions in the form of UXO, DMM, and/or MPPEH. Exposure to MEC could result in death or injury to workers, with the exception of public access provisions outlined through the 2011 PA process (see Section 4.4.10, Cultural Resources). The general public would be excluded from entering construction zones and training areas. To reduce the potential hazards related to the exposure to MEC, ESS documentation would be prepared that outlines specific measures that would be implemented to ensure the safety of workers and the general public. BMPs that would be implemented include having qualified UXO personnel perform surveys to identify and remove potential MEC items before beginning ground-disturbing activities. Additional safety precautions would include having UXO personnel supervision during earth-moving activities and providing MEC awareness training to construction personnel involved in grading and excavations before and during ground-disturbing activities. In addition, the DON provides MEC awareness training to GovGuam and other public representatives, allowing access to project sites to facilitate surveys and collection of natural resources or items of cultural significance prior to conducting vegetation clearance. Because UXO would be identified and removed before beginning construction activities, and construction personnel would be trained about the hazards associated with unexploded military munitions, potential direct or indirect impacts from encounters with UXO would be minimized and would be less than significant.
Traffic Incidents

Potential long-term traffic incident increases would be similar to those discussed under Alternative 2. The potential for increased traffic incidents is small (5% increase [see Section 4.1.17.2]). Because no high crash frequency intersections are located near NAVMAG, and the overall potential long-term increase in the number of traffic accidents as a result of the increase in personnel would be minimal, a less than significant impact is anticipated on the health and safety of the citizens of Guam from traffic incidents.

5.3.18 Environmental Justice and the Protection of Children

5.3.18.1 Affected Environment

The affected environment under the NAVMAG (North/South) alternative is considered to be the entire island of Guam, as discussed in Section 4.1.18.1 of this SEIS. The NAVMAG (North/South) proposed action under this alternative would be located within the southern region of Guam, as defined in Section 4.1.18.1. The villages of Santa Rita, Agat, Umatac, Talofofo, and Yona are within this region.

5.3.18.2 Environmental Consequences

Potential impacts to environmental justice populations from Alternative 3 would be to noise, recreation, land acquisition, and public health and safety. The impact analysis discussion provided in the following sections is focused primarily on operational impacts of implementing the proposed Alternative 3, as LFTRC construction impacts as related to environmental justice would be minimal and short-term, with no measurable effect on Guam’s special-status populations.

Noise

The potential impacts for Alternative 3 would be the same as Alternative 2.

Recreation

While there are fewer public recreational resources in the south, there are several resources along the coast as described in Section 5.3.7. Potentially affected resources include Talofofo Falls Park and Hiking Trail.

In Alternative 3, only a small portion of the SDZ extends outside NAVMAG property and there are no recreational resources that would be impacted by use of this area for LFTRC activities. There would be less than significant impact to recreational resources during the construction phase. There would also be less than significant impact to recreational resources during the operation of this LFTRC.

Land Acquisition

There would be short and long-term, direct and indirect significant adverse impacts to land ownership if there is an unsolicited sale of privately-owned land to the federal government for Alternative 3. Although there may be landowners who are interested in selling their land, land ownership impacts are considered significant until negotiations have been completed. There would also be other relocation activity and land acquisition, or long-term leases for roadway improvements, to implement this alternative.

Tier 1: Are there any minority, low-income, or children populations that would be impacted?

Yes, based on the data provided in Section 4.1.18.1, the private landowners are likely to be racial minorities that live in areas with a higher poverty rate than the U.S.
Tier 2: Are the applicable disadvantaged groups disproportionately affected by the negative environmental consequences of the proposed action(s)?

No, because all of Guam is considered a racial and ethnic minority population, minorities would not experience disproportionately high and adverse effects due to land acquisition. Because federal regulations regarding land acquisition would ensure that significant economic impacts to landowners and occupants do not occur, low-income populations would not experience disproportionately high and adverse effects due to land acquisition. Land acquisition would not result in health and safety risks that would disproportionately impact children. Therefore, Alternative 3 would not result in disproportionate land use or socioeconomic impacts to minority and low-income populations or children as a result of land acquisition.

Public Health and Safety

No impacts to public safety are anticipated from operational safety concerns (i.e., explosive safety, electromagnetic safety, construction safety). No impacts to public health and safety are anticipated from management of hazardous substances. Less than significant impacts are anticipated to public health and safety from firing range air emissions. Less than significant impacts are anticipated from construction and operational noise, water quality, and UXO.

Tier 1: Are there any minority, low-income, or children populations that would be impacted?

Yes, the populations of the villages affected by Alternative 3 have high percentages of racial minorities, low-income groups, and children.

Tier 2: Are the applicable disadvantaged groups disproportionately affected by the negative environmental consequences of the proposed action(s)?

No, impacts would not be disproportionate because regardless of where the LFTRC is located on Guam, high (relative to the U.S.) percentages of minorities, low-income residents, and children would be affected. As LFTRC alternatives may only occur on Guam (by international treaty), and all of Guam is considered to have a high proportion of minorities, low-income residents, and children, impacts cannot be considered disproportionate.
5.4 NAVAL MAGAZINE (L-SHAPED) LIVE-FIRE TRAINING RANGE COMPLEX -
ALTERNATIVE 4

Under Alternative 4, the proposed development of a live-fire training range complex would occur at
NAVMAG L-Shaped. Details about this alternative are provided in Section 2.5.4.4 and the proposed site
is illustrated in Figure 2.5-5.

5.4.1 Geological and Soil Resources

5.4.1.1 Affected Environment

The affected environment for the HG Range at Andersen South would be the same as described under
Alternative 1 in Section 5.1.1.1 of this SEIS.

The affected environment for geological and soil resources associated with Alternative 4 is consistent
with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 3: Geological and
Soil Resources, Section 3.1.5: South, pages 3-26 to 3-28), which is summarized below for reference. The
proposed reduction in the number of relocating Marines and dependents under the 2012 Roadmap
Adjustments does not alter the description of the affected environment for geological and soil resources,
but it would reduce some potential impacts to geological and soil resources that were determined to be
less than significant or mitigated to less than significant in the 2010 Final EIS, as described in the analysis
of environmental consequences for Alternative 4 below.

This alternative combines the land areas of the other two NAVMAG alternatives. Therefore, Alternative 4
would be located in the same mountainous part of south-central Guam as Alternatives 2 and 3 (Figure
5.4.1-1). Elevations within Alternative 4 range from approximately 310 feet (95 m) above MSL in the
southeast near the KD Rifle Range to approximately 700 feet (213 m) MSL to the MPMG Range in the
northwest (Figure 5.4.1-2). Fena Valley Reservoir lies between the southeastern and northwestern extent
of the proposed Alternative 4 footprint.

Bedrock in the northwestern portion of the Alternative 4 footprint (where the MPMG Range would be
located) is old (Barrigada) limestone, the geologic setting for sinkholes (see Section 3.1.1.1). Based on
available topographic and field data, three features have been preliminarily identified as
sinkholes/depressions that may contain sinkholes within, or on the perimeter of, the proposed Route
MPMG Range footprint and its associated range road in the northwestern portion of Alternative 4
(Figure 5.4.1-1). The remainder of the Alternative 4 footprint is underlain by bedrock of volcanic origin.
One minor bedrock fault crosses the northwestern portion of the Alternative 4 footprint, and there are
multiple faults in the surrounding area.

The soil types and their properties in the Alternative 4 footprint are the same as those described for
Alternatives 2 and 3 (Figure 5.4.1-2). Briefly, for nearly all of the soil types in the Alternative 4 footprint,
runoff is medium to rapid, and the water erosion hazard is moderate to severe (Young 1988). The
exception is the Ritidian-Rock Outcrop Complex soil found in the northwestern corner of Alternative 4,
for which runoff is very slow and the water erosion hazard is slight.

Sources: NAVFAC Pacific 2013; NRCS 2006
With respect to geologic hazards (see Section 3.1.1.1), most conditions at the proposed Alternative 4 location are the same as for Alternative 3 (i.e., consolidated bedrock underlying the site is not vulnerable to liquefaction; the site elevation is higher than the maximum recorded tsunami wave run-up; limestone bedrock the area of the Alternative 4 MPMG Range presents a potential hazard of surface instability and collapse due to sinkholes). Three features have been preliminarily identified as sinkholes/depressions that may contain sinkholes within, or on the perimeter of, the Alternative 4 footprint in limestone bedrock. The other Alternative 4 firing ranges and the Magazine Relocation Area would be located on volcanic bedrock, in which sinkholes typically do not form. In the northwestern portion of the site, where the MPMG Range would be located, the landslide potential is moderate. The southwestern portion where the other ranges would be located has a high landslide potential (see Figure 5.4.1-1).

5.4.1.2 Environmental Consequences

Construction

Potential geology and soil impacts addressed in this section are limited to elements of the proposed action that could affect onshore landforms or that could be affected by geologic hazards. Potential soil contamination issues are addressed in Section 5.4.16.2, Hazardous Materials and Waste of this SEIS.

Construction impacts associated with the HG Range at Andersen South would be similar to those described under Alternative 1 in Section 5.1.1.2 of this SEIS.

Construction activities for Alternative 4 would be the similar to those described for Alternative 3, except that an estimated 66 new concrete munitions magazines would be constructed as compared with 72 new magazines for Alternative 3. Earthwork would include 2,716,125 yd$^3$ (2,076,627 m$^3$) of cut and 2,767,463 yd$^3$ (2,115,878 m$^3$) of fill, resulting in a net of 51,337 yd$^3$ (39,250 m$^3$) of fill (DON 2013a). Alternative 4 would involve the largest volume of excavation to construct of any of the action alternatives except Alternative 3 (Alternative 3 would involve the greatest; Alternative 2 would require the least). Within the Alternative 4 footprint, there are major differences in elevation in the areas planned for construction of the MPMG and KD Rifle ranges. There would be substantial changes to surface elevation for construction of the MPMG and KD Rifle ranges (DON 2013b). Because of the major elevation changes, the substantial alteration of the surrounding landscape, and the amount of excavation, filling, stream re-routing and contouring that would occur, NAVMAG (L-Shaped) LFTRC alternative is expected to have a significant direct, long-term impact on topography. Potential mitigation is not considered feasible for this impact because smaller cut/fill volumes would not provide the necessary level surfaces for the referenced ranges. The significant impact to topography would occur with implementation of any LFTRC alternative except Alternative 2, which would involve the least amount of cut and fill (i.e., the impact would be similar for all alternatives except Alternative 2).

Construction of the HG Range would involve 8,894 yd$^3$ (6,800 m$^3$) of cut and 12,641 yd$^3$ (9,665 m$^3$) of fill, for a net of 3,747 yd$^3$ (2,865 m$^3$) of fill. Thus, the total net fill for Alternative 4 would be 55,084 yd$^3$ (42,115 m$^3$).

Alternative 4 would site the MPMG Range in the same steeply-sloped area as Alternative 3, and the remaining ranges in the less steep Alternative 2 footprint. The differences in elevation in the northern portion of the Alternative 4 area planned for construction of the MPMG Range are substantially greater than the natural elevation differences in the Alternative 2 footprint. To construct the MPMG Range at Alternative 2, a 30-feet (10-m) high slope would be leveled with about 942,500 yd$^3$ and (725,000 m$^3$) of cut and 910,000 yd$^3$ (700,000 m$^3$) of fill. To construct the same range at Alternative 4, a 75-to-100 feet (22 to 30 m) high slope would be leveled with 2.47 million yd$^3$ (1.9 million m$^3$) of fill. Due to the steeper
topography in the Alternative 4 footprint, more than twice as much excavation and fill would be needed overall to level the ranges for Alternative 4 as for Alternative 2. There is a potential for increased erosion, compaction, and soil loss from physical disturbance caused by construction activity and changes to existing topography. However, project design and construction would incorporate engineering controls as BMPs to minimize erosion within the project construction footprint, as required by Title 22 of GAR, Chapter 10 Guam Soil Erosion and Sediment Control Regulations. Examples of such engineering controls are described in Section 5.2.1.2 of this SEIS.

In addition, construction activities associated with Alternative 4 would comply with the Construction General Permit. Potential construction-specific stormwater BMPs would be implemented in compliance with the Construction General Permit. Construction-specific stormwater BMPs would provide erosion and sediment control during the construction period, generally by employing off-site measures that reduce the flow of stormwater and minimize the transport of soils and sediment off-site. Fill material would be generated off-site, whenever possible. In addition, roadway-specific BMPs, as identified in the most recent CNMI and Guam Stormwater Management Manual, would be included in the planning, design, and construction of all roadways and facilities. Through compliance with 22 GAR Chapter 10 and the Construction General Permit and implementation of roadway stormwater BMPs, and because the rate of erosion and soil loss would not be substantially increased, direct, short-term impacts to soils from erosion during construction of Alternative 4 would be less than significant. No indirect, short-term impacts associated with soil erosion are expected.

Construction of Alternative 4 would disturb agriculturally productive soils that are identified by the USDA as prime farmlands. As described in Section 5.2.6, Land and Submerged Land Use of this SEIS, no existing agricultural use is identified for the area of disturbance. Therefore, disturbance of these soils for construction of Alternative 4 would be an adverse, but less than significant direct, long-term impact to agricultural soils.

There are three topographic features that may contain sinkholes within, or on the perimeter of, the Alternative 4 footprint (see Figure 5.4.1.1). For any sinkholes discovered before or during construction, BMPs would include compliance with 22 GAR Chapter 10 § 10106F. In order to ensure compliance with 22 GAR Chapter 10 § 10106F, BMPs would be modified or an environmental and hydrogeologic assessment must be performed to ensure adverse effects will not result, including but not limited to the displacement of groundwater, interference with well production, significant changes to groundwater recharge, flooding, or the threat or introduction of any pollutant to groundwater. After a preferred alternative is selected and the ROD is signed for the proposed project, final design work would begin for the preferred alternative site. A geotechnical study, including subsurface borings, would be conducted to determine whether the depressions on the site contain sinkholes, and whether there are additional sinkholes not evident from the surface. Hydrogeological studies would be conducted to confirm groundwater flow at the site as well. The geotechnical and hydrogeological studies would be coordinated with the GEPA to design and implement an appropriate analysis. These studies would be part of the final design process and would take place before any construction begins. With implementation of these BMPs, and since no sinkholes would be filled that would adversely affect site drainage, no adverse impacts to sinkholes would occur. Therefore, construction of Alternative 4 would have less than significant direct, short-term impacts to sinkholes.

Hazards associated with earthquakes, fault rupture and slope instability would be minimized by adherence to UFC 3-310-04 Seismic Design of Buildings dated June 1, 2013 (USACE 2013). The Alternative 4 site is located inland and above the elevation prone to tsunamis, and so would not be susceptible to
inundation. The consolidated limestone and volcanic bedrock underlying the site is not vulnerable to liquefaction. In addition, there would not be a change to soil and/or bedrock conditions that would increase vulnerability to a geologic hazard. As stated in the previous paragraph, 22 GAR Chapter 10 § 10106F requires that for sinkholes within the project development footprint that would be modified or used, an environmental and hydrogeologic assessment must be performed to ensure adverse effects will not result. Compliance with these regulations would minimize potential geologic hazards associated with sinkholes. Therefore, construction of Alternative 4 would have less than significant direct and indirect short-term impacts with respect to geologic hazards.

Operation

Operational impacts associated with the HG Range at Andersen South would be similar to those described under Alternative 1 in Section 5.1.1.2 of this SEIS.

Alternative 4 operations would not alter topography post construction, so no direct or indirect impact to topography would occur.

The firing range activities and conditions and conditions that may directly cause or increase naturally occurring soil erosion during the operational phase would be the same as for Alternative 3 and are described in Section 5.2.1.2 of this SEIS. Similar to Alternative 3, under Alternative 4 the significant long-term changes to topography during construction of the MPMG and KD Rifle ranges could alter natural surface flow patterns that could increase soil erosion. Munitions storage in the relocated magazines would not involve any surface disturbance other than minimal excavation for utility maintenance.

The area of impervious surfaces that would be constructed for the ranges and associated infrastructure (range buildings, roads, and parking areas) would be approximately 33.3 acres (13.5 ha) total (Appendix F) including about 32.4 acres (13.1 ha) for Alternative 4 and about 0.9 acre (0.4 ha) for the HG Range. There would be a minor increase in runoff from the new impervious surface area as compared with existing conditions. Stormwater infrastructure improvements included as part of the proposed action would incorporate LID measures and BMPs to minimize soil erosion from this increased runoff. Where possible, stormwater flow paths would continue to mimic pre-development flows through area topography. During the operations phase, stormwater BMPs that would be implemented to minimize and control runoff would also minimize soil erosion.

The range complex would be managed in accordance with current Marine Corps range management policies and procedures, which are designed to ensure the safe, efficient, effective, and environmentally sustainable use of the range area. A thorough explanation of Marine Corps range management is detailed in the 2010 Final EIS (Volume 2, Chapter 2: Description of Proposed Action and Alternatives, Section 2.3.1.4: Firing General Military Skills, pages 2-55 to 2-59). Marine Corps range management policies and procedures include procedures for removing expended rounds from live-fire ranges with impact berms every 5 years, managing stormwater, controlling erosion, maintaining vegetation on berms and drainage ways and turf on the range, and restricting vehicular activities to designated/previously identified areas. Range roads would be maintained to minimize erosion.

There would be minor ground disturbance associated with utility maintenance. Construction stormwater BMPs would be implemented during maintenance activities to minimize and control runoff on-site and minimize potential effects of erosion.
USDA-identified prime farmland soils in the proposed NAVMAG (L-Shaped) LFTRC area would be disturbed. However, there are no existing agricultural uses of the soils that would be disturbed. Therefore, Alternative 4 operations would have a less than significant direct, long-term impact to agricultural soils.

A potential indirect impact of firing range operations includes the possibility of live ammunition causing wildland fires. As a BMP and in accordance with range safety protocols, a Range Fire Management Plan would be prepared, based on the DON’s Wildland Fire Management Plan (USFS 2008). It would include protocols for monitoring fire conditions and adjusting training as needed. Units undergoing training at the ranges would be briefed by range control on requirements suitable to the conditions of the day and protocols should a fire occur (e.g., specifying how the range would shut down and how fire suppression action would be taken). The existing Wildland Fire Management Plan (USFS 2008) that covers NAVMAG would be extended to cover bordering non-federal lands that could spread fire onto the ranges and would continue to be implemented under Alternative 4. With these measures, potential wildfires caused by the live ammunition would be unlikely. Effects to soils from erosion associated with wildfires associated with operation of Alternative 4 would be minimal and direct and indirect impacts would be less than significant.

With implementation of Marine Corps range management policies and procedures, fire suppression and potential mitigation measures, and stormwater BMPs (for ranges and ground-disturbing maintenance) less than significant direct and indirect long-term impacts to soils from erosion would occur due to Alternative 4 range operations.

The BMPs for sinkholes would be implemented in the event that maintenance activities should involve sinkholes or their immediate perimeter, so no adverse impacts to sinkholes would occur. Therefore, Alternative 4 operations would have less than significant direct, long-term impacts to sinkholes.

Hazards associated with earthquakes, fault rupture and slope instability would be minimized by adherence to UFC 3-310-04 Seismic Design of Buildings dated June 2013 (USACE 2013) during project design and construction so direct and indirect long-term impacts with respect to seismic hazards would be less than significant. The bedrock underlying the site is not vulnerable to liquefaction. The Alternative 4 location is inland and higher than the elevation prone to tsunamis, so it would not be susceptible to inundation. In addition, there would not be a change to soil and/or bedrock conditions that would increase vulnerability to a geologic hazard. Implementation of sinkhole BMPs would minimize potential geologic hazards associated with sinkholes. Therefore, Alternative 4 operations would have less than significant direct and indirect long-term impacts associated with geologic hazards.

5.4.2 Water Resources

5.4.2.1 Affected Environment

The affected environment for the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.2.1 of this SEIS. The rest of the Alternative 4 project area (Figure 5.4.2-1) overlaps the Alternative 2 and 3 project areas and the Alternative 4 affected environment for water resources is the same as described under Alternative 2 and 3 in Sections 5.2.2.1 and 5.3.2.1, respectively, of this SEIS. A summary of site conditions for Alternative 4 is provided in Appendix F.

Recent off-site wetland confirmation surveys were conducted at NAVMAG in May and November 2012 for this SEIS. The off-site confirmation was a non-jurisdictional wetland delineation (delineation being the establishment of wetland boundaries). A jurisdictional delineation establishes the boundaries of wetlands that are subject to requirements in the CWA and its implementing regulations and requires the approval of the USACE.
Figure 5.4.2-1
Surface Waters and Wetlands in the Vicinity of NAVMAG (L-Shaped) LFTRC Alternative 4

Sources: WERI 2001; USGS 2003; FEMA 2007; USFWS 2010; NAVFAC Pacific 2013
The wetlands identified during the 2012 survey are palustrine emergent wetlands with persistent vegetation that are either seasonally flooded/saturated (PEM1E) or semi-permanently flooded (PEM1F). The 2012 field survey delineated a total of 25.2 acres (10.2 ha) of wetlands in the project area as shown in Figure 5.4.2-1 and Table 5.4.2-1 (NAVFAC Pacific 2013b). This total includes 3.3 acres (1.3 ha) of forested wetlands as mapped by USFS (2006). All of these wetlands are all considered potentially jurisdictional pending a Jurisdictional Determination by the USACE.

For portions of the project area located outside the 2012 field survey, NWI data was used (NWI maps indicate the potential for wetland areas, but are not official determinations). The NWI maps indicate 7.0 acres (2.9 ha) of NWI wetland areas as shown in Table 5.2.2-1 and Figure 5.2.2-2 (USFWS 2010). The NWI wetlands are identified as palustrine emergent wetlands with persistent vegetation that are either seasonally flooded (PEM1C) or semi-permanently flooded (PEM1F); palustrine forested that are seasonally flooded (PFO3C); and palustrine scrub/shrub vegetation that are seasonally flooded (PSS1C).

The project area outside the 2012 survey area would require a wetland delineation survey and review by the USACE to verify the location and size of any wetlands and whether they are jurisdictional.

5.4.2.2 Environmental Consequences

**Construction**

General construction impacts to water resources would be similar to those described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.4: South, page 4-112) and under Alternative A in Section 4.1.2.2 of this SEIS. Alternative 4 would occur in an area that contains waters of the U.S. and would be required to comply with the Construction General Permit as described under Alternative A in Section 4.1.2.2 of this SEIS. Construction impacts associated with the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.2.2 of this SEIS.

Under Alternative 4, proposed LFTRC construction activities at NAVMAG and non-DoD lands would result in the potential for a short-term increase in stormwater runoff, erosion, and sedimentation. However, through compliance with the Construction General Permit and Program SWPPP and implementation of a site-specific SWPPP and associated erosion control, runoff reduction, and sediment removal BMPs (see Table 4.1.2-2), these effects would be minimized. Specifically, the site-specific SWPPP would identify appropriate BMPs for the site that would serve to contain runoff and sediment off-site by reducing the flowrate of runoff and thereby minimize transport of suspended sediment through settling and promote infiltration of runoff.
Surface Water

Surface waters that are potentially affected by the various project footprints are shown in Figure 5.4.2-1. The MPMG Range would drain to the Talisay River. The Non-standard Small Arms Range would drain to an unnamed tributary of the Sagge River. The MRF Range and the majority of the KD Rifle Range would drain to Sarasa River. The remaining portion of the KD Rifle Range and the pistol range would drain into the Bubulaon River at the northern extent of the Ugum Watershed (NAVFAC Pacific 2013a). The access road would cross the Bubulao and Ugum rivers. The range roads would cross the Sarasa, Malaja, and Bubulao rivers. The Magazine Relocation Area would be located in the Central Talofofo Watershed and has the potential to contribute to sedimentation of Fena Valley Reservoir. Construction under Alternative 4 would include clearing of vegetation, grading (cut and fill), permanent or temporary accumulation of soils, stream rerouting, and filling in of natural areas. Potential effects from stormwater runoff would be minimized by adhering to the provisions of the Construction General Permit and implementing of a Program SWPPP and site-specific SWPPP and associated BMPs that would address site- and activity-specific surface water protection requirements. Implementation of construction BMPs under Alternative 4 would also minimize sedimentation impacts to Fena Valley Reservoir and support the compliance with load allocations under the sediment TMDL for Ugum Watershed.

Construction activities that involve substantial earth moving and those that are within or near stream channels would be scheduled for the dry season (January to May), to the extent possible (NAVFAC Pacific 2013a). Measures to minimize erosion within the project construction footprint, stabilize banks, and protect stream channels would be the same as described under Alternative 2 in Section 5.2.2.2 of this SEIS. Given the short-term nature of potential surface water impacts, compliance with Construction General Permit requirements, and implementation of BMPs, construction activities associated with Alternative 4 would result in less than significant short-term impacts to surface water.

Groundwater

Construction activities under Alternative 4 would include stormwater runoff protection measures that would also serve to protect groundwater quality. By adhering to the provisions of the Construction General Permit and implementing BMPs associated with addressing site- and activity-specific water resource protection requirements, there would be a reduction in stormwater pollutant loading potential and thus a reduction in pollution loading potential to the underlying groundwater basins. Given stormwater runoff protection measures (i.e., compliance with Construction General Permit requirements and implementation of BMPs), construction activities associated with Alternative 4 would result in less than significant short-term impacts to groundwater.

Nearshore Waters

Construction activities associated with Alternative 4 would occur more than 1 mile (1.6 km) from the coastline and would not result in direct impacts to the nearshore waters from stormwater runoff. Compliance with the Construction General Permit and implementation of BMPs under Alternative 3 would protect water quality in the Talofofo River and support the compliance with load allocations under the sediment TMDL for Ugum Watershed, ensuring that stormwater runoff from the project area would not cause indirect impacts to nearshore waters in Talofofo Bay (see Figure 5.2.2-1). Given stormwater runoff protection measures (i.e., compliance with Construction General Permit requirements and implementation of BMPs), construction activities associated with Alternative 4 would result in no impacts to nearshore waters.
Wetlands

Implementation of Alternative 4 could result in long-term, direct impacts to up to 25.2 acres (10.2 ha) of potentially jurisdictional wetland areas (see Figure 5.4.2-1). These direct impacts would be at the MPMG and KD Rifle ranges and range roads. There are an additional 7.0 acres (2.9 ha) of NWI wetlands in portions of the project area that have not been surveyed (see Section 5.2.2.1 in this SEIS).

Direct impacts (fill) to jurisdictional wetlands would be a significant impact. If these wetland areas are determined to be jurisdictional by the USACE, and therefore subject to Section 404 requirements, the Marine Corps would first attempt to avoid impacts. If avoidance is not possible, then the Marine Corps would obtain a Section 404 permit from the USACE to fill the wetlands and comply with minimization and potential mitigation measures outlined in the permit (see Table 5.7-1). Unavoidable direct impacts to jurisdictional wetlands would be mitigated by creating new wetlands, restoring or enhancing existing wetlands, or preserving existing wetland areas on Guam to, at a minimum, replace the area filled at a mitigation ratio greater than 1:1.

As described under Alternative 2, a mitigation plan would be prepared under Alternative 3 as part of the Section 404 permitting process. If Alternative 4 is chosen and wetlands cannot be avoided, the Marine Corps understands that a LEDPA determination must be made as part of the permitting process and that if the USACE determines this alternative is not the LEDPA, a Section 404 permit under the CWA cannot be granted and Alternative 4 would not be implemented. Through implementation of the potential mitigation measures and procedures identified above, significant impacts to wetlands would be reduced to a level below significant. By comparison, Alternatives 1 and 5 would have no impacts to wetlands and Alternatives 2 and 3 would have significant long-term, direct impacts to up to 17.7 acres (7.2 ha) and 36.9 acres (15.0 ha) of potentially jurisdictional wetland areas, respectively, which would be mitigated to a level below significant.

There would also be potentially jurisdictional wetlands adjacent to and downstream of construction areas that would be subject to potential indirect impacts during construction. These short-term, indirect impacts would be minimized by adhering to the provisions of the Construction General Permit and implementing BMPs associated with addressing site- and activity-specific stormwater runoff protection requirements.

Operation

Alternative 4 would incorporate the concept of LID in the final planning, design, and permitting of the stormwater runoff and drainage design as described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.1: North, pages 4-85 to 4-87) and under Alternative A in Section 4.1.2.2 of this SEIS. Operation impacts associated with the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.2.2 of this SEIS.

Under Alternative 4, there would be a minor increase in the area of impervious surface as a result of ranges and associated support facilities, which would result in an associated increase in stormwater discharge intensities and volume. However, the proposed action would incorporate LID measures and BMPs to ensure stormwater retention would be consistent with local and federal requirements and thus minimize potential impacts to surface water quality. Alternative 4 would also be implemented in accordance with all applicable orders, laws, and regulations including the preparation and implementation of a SWPPP, SWMP, and SPCC plan that would control runoff and minimize potential leaks and spills. Where possible, stormwater flow paths would continue to mimic pre-development flows through area topography.
Alternative 4 would include implementation of the REVA program and range management preventative measures (i.e., vegetation, pH adjustment, LID). As listed in Section 2.8 of this SEIS, the BMPs would reduce the potential for contaminants to migrate off-site. In addition, the DoD would investigate additional technologies that could assist with range design and management to minimize potential impacts. Available baseline data regarding range site conditions would be reviewed and verified prior to range construction and regular monitoring would occur during operations to verify the effectiveness of BMPs. For each range, water quality treatment strategies would be selected to achieve reductions of non-point source pollutants to meet the same water quality requirements as identified under Alternative A in Section 4.1.2.2 of this SEIS.

**Surface Water**

The *Watershed Reconnaissance Study* (NAVFAC Pacific 2013a) identified potential direct and indirect impacts to surface waters during the operational phase of Alternative 4, as described under Alternative 2 in Section 5.2.2.2 of this SEIS (see Appendix F). Potential effects from stormwater runoff would be minimized through the implementation of an appropriate and comprehensive stormwater management plan utilizing a LID approach and BMPs under Alternative 4. Implementation of LID measures and BMPs under Alternative 4 would also support the compliance with load allocations under the sediment TMDL for Ugum Watershed.

Firing range operational-phase LID measures and BMPs would focus on reducing volume and velocity of stormwater runoff, minimizing soil erosion potential within the range boundaries, and controlling the spread of lead bullets and bullet fragments. Implementation of the REVA program and BMPs for containing and limiting off-site migration of lead contaminants would be the same as described under Alternative 2 in Section 5.2.2.2 of this SEIS and are listed in Section 2.8 of this SEIS.

Appropriate fire suppression and potential mitigation measures would also be incorporated into the design (fire resistant structures) and range operating procedures as described under Alternative 2 in Section 5.2.2.2 of this SEIS. The portion of the Alternative 4 project area on non-federal lands would have the same fire susceptibility compared Alternative 2, while the portion of the project area on NAVMAG would have a reduced fire susceptibility compared to Alternative 2. The existing Wildland Fire Management Plan (USFS 2008) that covers NAVMAG would be extended to cover the non-federal lands and would continue to be implemented under Alternative 4. Therefore, the risk of exposing soils to erosion due to arson or natural wildland fires would be relatively lower for Alternative 4 ranges located within NAVMAG.

Because none of the proposed Alternative 4 firing range footprints fall within the Central Talofofo Watershed, stormwater runoff from the proposed range footprint areas would not drain to the Fena Valley Reservoir (see Figure 5.4.2-1). The Magazine Relocation Area would be located in the Central Talofofo Watershed and has the potential to contribute to sedimentation of Fena Valley Reservoir. However, the magazine would include appropriate LID measures and BMPs to minimize erosion within the project construction footprint and transport of sediment to surface waters. The SDZ associated with Alternative 4 would partially overlay the Central Talofofo Watershed (see Figure 5.4.2-1), but potential impacts to the water quality of Fena Valley Reservoir from expended projectiles would be negligible as described under Alternative 2 in Section 5.2.2.2 of this SEIS.

No buildings/structures would be constructed in the 100-year or 500-year flood zone. It is anticipated that developing the proposed footprint areas would not impact water surface elevation levels in FEMA-regulated floodplains. However, this would be confirmed through detailed hydraulic and hydrologic
modeling during the final design phase. Any rise in the elevations would be covered by FEMA regulations and would need to be approved by the local floodplain administrator.

Alternative 4 operations would be conducted in accordance with all applicable orders, laws, and regulations including the preparation and implementation of a SWPPP, SWMP, and SPCC Plans that would control runoff and minimize potential leaks and spills. Given implementation of these stormwater runoff protective measures and range operation BMPs for containing and limiting the migration of lead contaminants, operations associated with Alternative 4 would result in less than significant long-term, direct or indirect impacts to surface water.

**Groundwater**

Under Alternative 4, proposed operations would be in compliance with the stormwater runoff protection measures identified above that would also serve to protect groundwater quality and recharge. Specifically, implementation of LID measures and the provisions of the SWPPP and associated erosion control activities would ensure that any stormwater runoff recharging to groundwater basins would be of acceptable quality. BMPs to minimize lead transport would minimize contamination of groundwater. Given stormwater runoff protection measures (e.g., implementation of the REVA program, LID, and SWPPP measures), operations associated with Alternative 4 would result in less than significant long-term, direct impacts to groundwater.

**Nearshore Waters**

Under Alternative 4, proposed operations would be in compliance with the stormwater runoff protection measures identified above that would also prevent direct impacts to the nearshore waters from stormwater runoff. Implementation of LID measures and BMPs under Alternative 4 would protect water quality in the Talofofo River and support the compliance with load allocations under the sediment TMDL for Ugum Watershed, ensuring that stormwater runoff from the project area would not cause indirect impacts to nearshore waters in Talofofo Bay. Given stormwater runoff protection measures (i.e., implementation of LID, BMPs, and pollution prevention plans), operations associated with Alternative 4 would result in no impacts to nearshore waters.

**Wetlands**

Under Alternative 4, proposed operations have the potential to cause indirect effects to nearby down-gradient wetland areas (see Figure 5.4.2-1). However, the stormwater runoff protection measures identified above would also serve to protect water quality entering wetlands. Specifically, implementation of LID measures and the provisions of the SWPPP and associated erosion control activities would ensure that the stormwater runoff flowing into wetlands would be of acceptable quality. Given stormwater runoff protection measures (i.e., implementation of LID, BMPs, and pollution prevention plans), operations associated with Alternative 4 would result in less than significant long-term, indirect impacts to wetlands.

**5.4.3 Air Quality**

**5.4.3.1 Affected Environment**

The areas around Alternative 4 are not developed and no sensitive populations are present. Ambient air quality conditions in these areas can be considered typical for a rural area and include few activities involving operations of either major stationary or mobile sources.
5.4.3.2 Environmental Consequences

The construction activities associated with Alternative 4 would be similar to Alternative 1, with the exception of site location. Therefore, the predicted construction activity annual emissions would be the same as Alternative 1, as summarized in Table 5.1.3-2, and are well below the significance criterion of 250 tpy.

The hot-spot air quality impacts during both construction and operational phases would be similar to Alternative 1, as discussed in Section 5.1.3; resulting in less than significant short-and long-term direct hot-spot air quality impacts.

5.4.4 Noise

5.4.4.1 Affected Environment

The affected environment for this alternative would be the same as both Alternatives 2 and 3 because this alternative uses a split firing range configuration and entails the use of both the north and southeast portions of NAVMAG and the surrounding area.

5.4.4.2 Environmental Consequences

Construction

Similar to Alternative 3, there would be no impact due to construction noise under Alternative 4 because construction activities would be in a sparsely populated area of Guam. Construction areas would be approximately 0.25 mile (0.4 km) away from the nearest receptors, a distance that is far enough away from the source of construction noise such that there would be minimal noise effects on receptors.

Operation

Noise levels under Alternative 4 would be very similar to both Alternatives 2 and 3 combined. In the north, the MPMG Range uses the loudest ammunition with the .50 cal rounds and it dominates the noise levels under Alternative 3. However, in the southeast noise levels would not be as high as described under Alternative 2 because the MPMG Range would be in the north.

Under Alternative 4, the Zone 2 noise contours cover approximately 296 acres (119 ha) beyond the boundaries of NAVMAG and Zone 3 covers 33 acres (13 ha). The off-base acreage would extend towards the north and west of NAVMAG and beyond the south and east boundaries. Modeling results (Army 2013) for the NAVMAG (L-Shaped) LFTRC are shown on Figure 5.4.4-1. No houses lie within the noise contours, and therefore no people would be affected by Zone 2 or Zone 3 noise contours. The same approximately 70-80 homes discussed in the North/South Alternative would be within the Zone I noise contours in the area along Route 12 adjacent to Our Lady of Guadalupe Church and would experience noise levels between 55 and 60 dB ADNL. Another approximately 100 homes would be within the Zone I contours in Agat near the Pagachao Guam Housing and Urban Renewal Authority housing area with noise levels approximately 55 to 68 dB ADNL. Although noise levels would be greater than existing levels, this area would still be considered compatible for residential use. Noise levels may be less than predicted because the area is on the opposite side of the hill from the proposed firing line and the area is heavily wooded. Both of these factors attenuate sound levels. Table 5.4.4-1 lists Noise Zones 2 and 3 and the associated acreage affected within each zone.

Note: Zone 1 is not listed because all land uses are compatible within Zone 1.
Source: Army 2013, NAVFAC Pacific 2013.

Under Alternative 4, no people would be impacted by Zone 2 or 3 noise levels because there are no residences within these zones. There would be no direct impacts due to live-fire training noise under Alternative 4 because there would be no populated residential areas affected and none of the noise significance criteria stated in the Marine Corps Guidance memo for land use and noise exposure would be exceeded (Marine Corps 2005). There would be no direct or indirect impacts because no population would be affected, and none of the impact assessment criteria related to potential noise impacts would be exceeded. As described in Section 5.1.4.2, noise levels at the HG Range would remain within Andersen South and not impact any residences. In summary, there would be no residences/households affected by noise resulting from implementation of Alternative 2 and, consequently, no significant noise impacts would occur.

In comparison, only Alternative 1 would potentially result in significant noise impacts; however, those impacts could be mitigated to less than significant through the use of berms and natural foliage.

5.4.5 Airspace

5.4.5.1 Affected Environment

The existing airspace conditions for Alternative 4 would be the same as described for Alternative 1 (see Section 5.1.5.1 of this SEIS). Detailed information on military and civilian air traffic associated with AAFB and Guam International Airport, respectively, is provided in the 2010 Final EIS (Volume 2, Chapter 7: Airspace, Section 7.1: Affected Environment, pages 7-8 through 7-10).

5.4.5.2 Environmental Consequences

Construction

No changes to airspace would be required during construction of the LFTRC under Alternative 4, and construction activities would not be expected to conflict or interfere with the use or management of existing airspace in the vicinity. Therefore, construction of the LFTRC under Alternative 4 would have no impact on airspace.
Operation

Figure 5.4.5-1 depicts the proposed Restricted Area associated with Alternative 4. This SUA would be needed to contain the vertical hazard associated with the proposed live-fire training. Boundary coordinates for the proposed NAVMAG (L-Shaped) Option B of R-7202 Guam would begin at:

- lat.13°22′56″N., long.144°39′54″E
- to lat.13°22′58″N., long.144°40′57″E
- to lat.13°19′34″N., long.144°43′28″E
- to lat.13°18′58″N., long.144°41′9″E
- to lat.13°20′13″N., long.144°39′56″E
- to the point of beginning

Altitudes, times of use, and controlling and using agencies for this Restricted Area SUA would be the same as described in Section 5.1.5.2 for Route 15 LFTRC Alternative 1. The proposed CFA associated with the HG Range at Andersen South would be the same as described in Section 5.1.5.2 and depicted in Figure 5.1.5-4.

Section 3.5.3.1 identifies the potential impacts to airspace from implementation of the LFTRC alternatives. Given its location, the proposed NAVMAG (L-Shaped) LFTRC Alternative would directly impact arrivals into and departures out of Guam International Airport. The FAA stated in the preliminary Airspace Feasibility Assessment (FAA 2013) that Alternative 4 is not feasible. However, the FAA stated that “an assignment of ‘not feasible’ to a specific alternative is not a statement of infeasibility, but merely an assessment of the airspace in regard to the level of assumed impact” (FAA 2013).

Operational activities under Alternative 4 have the potential for significant direct impacts to aviation due to the following:

- Guam International Airport Airspace and instrument approach procedures.
- IFR/VFR traffic flows.
- Terminal operations.

However, if this alternative is selected, long-term impacts and potential mitigation would be further studied through the DON/FAA/Air Force consultation process. The general types of potential mitigation measures that could be employed may include adjusting airspace per FAA coordination and/or adjusting LFTRC operation procedures if feasible. However, no specific potential mitigation measures are proposed at this time.

As detailed in Table 5.7-1, operational impacts under Alternative 4 would be the same as under Alternatives 1, 2, and 3. Operational impacts under Alternative 4 would be greater than impacts under Alternative 5.
Figure 5.4.5-1
Proposed SUA Associated with LFTRC Alternative 4

Source: NAVFAC Pacific 2013
5.4.6 Land and Submerged Land Use

5.4.6.1 Affected Environment

All LFTRC alternatives include a HG Range at Andersen South, the affected environment and impacts of which are described in Section 5.1.6 of this SEIS.

The proposed Alternative 4 requires acquisition of areas adjacent to the NAVMAG on the eastern and southwestern boundaries. In addition to the land required for the expanded NAVMAG installation boundary, land would be acquired for the access road connection to Route 4 (see Figure 5.2.6-1). The acreages to be acquired are described in Section 2.5.4.7, Summary of LFTRC Alternatives, Table 2.5-3. Most of the land proposed for acquisition is privately owned (see Figure 5.2.6-1). Additional detail on the number of lots affected and land ownership is provided in Section 5.2.15, Socioeconomics and General Services. No submerged land is impacted by implementation of Alternative 4 (Figure 5.4.6-1).

The primary existing land uses within NAVMAG are as described in Section 5.2.6. Alternative 4 would require relocation of existing NAVMAG munitions storage facilities within NAVMAG (see Figure 2.5-5).

All of the land proposed for acquisition is undeveloped and in its natural state (Appendix D SIAS; Figure 5.3-21, Table 5.3-4). There are no land use plans for the community surrounding the NAVMAG area of Guam. The GBSP land classification for the proposed acquisition area is Agriculture. However, as described in the Terrestrial Biological Resources Section 5.4.8, the acquisition area is within the Guam Bolanos Conservation Area, which is under Guam Department of Agriculture jurisdiction. Approximately 4.5% of Guam’s USDA-designated prime and less than 1% of USDA-designated important farmlands were identified in the eastern acquisition area (Figure 5.4.6-1). No current agricultural use was identified in the aerial photographs.

Adjacent land uses to the NAVMAG (L-Shaped) LFTRC area include other NAVMAG land uses and non-federal lands that are classified by GBSP as Agriculture (Figure 5.4.6-1). There are residential areas (sensitive receptors) adjacent and east of the acquisition area and north, but not adjacent to the proposed MPMG Range.

Mount Lamlam and Mount Jumullong Manglo were identified west of the SDZs, but not adjacent (Figure 5.4.6-1).

5.4.6.2 Environmental Consequences

Land use impacts are addressed in this section. Land ownership impacts are addressed in Section 5.4.15, Socioeconomics and General Services.

Construction

As previously discussed in Chapter 3, Section 3.6.3.1, all changes in land use are considered long-term operational impacts. Therefore, there is no construction-phase analysis for this resource under any of the alternatives.

Operation

Potential impacts on Fena Valley Reservoir and water supply are addressed in the Water Resources Section 5.2.2. LFTRC land use would be compatible with the existing military NAVMAG land use, except the use of the southern land navigation area would be discontinued and magazines would be relocated (see Figure 2.5-5). Any direct or indirect land use incompatibility issues related to the military mission within NAVMAG would be resolved through application of installation master planning guidelines outlined in UFC 2-100-01. Therefore, long-term land use impacts to NAVMAG would be less than significant.

The proposed NAVMAG (L-Shaped) LFTRC Alternative 4 would restrict GovGuam and public access to the portion of the Bolanos Conservation Area that would be within the land acquisition area. The impact of the long-term reduced access on conservation goals and objectives is primarily a terrestrial biological resources (Section 5.4.8) impact. As described in Section 3.6.3, Approach to Analysis, new access restrictions placed on non-DoD populations would be a potentially long-term direct significant impact when access to a specific community-valued land use would be affected. In addition, the reduction or loss of a valued land use would be a potentially significant long-term adverse impact. There would be potentially significant impacts associated with (1) new access restrictions and (2) the reduction in the Bolanos Conservation Area land use. The following may be a potential mitigation measure to reduce these impacts to a less than significant level:

- DoD would work with GovGuam to develop a plan to balance the loss of conservation land use and access with the operational needs and public safety concerns.

Indirect less than significant impacts to existing land use or GBSP classification of Agricultural land use were identified. The acquired area would largely remain as open space. USDA-designated prime and important farmlands were identified within the eastern acquisition area but the area is not currently used for agriculture. The loss of prime and important farmland is a long-term adverse impact, but is considered less than significant because it is not currently farmed and there are other prime and important farmlands available for agricultural use.

The proposed NAVMAG (L-Shaped) LFTRC would be compatible with surrounding vacant and residential land uses. The Zone 3 noise contour would extend slightly off-base near the ranges proposed in the east, as described in Section 5.4.4., Noise, and shown on Figure 5.4.4-1. The Zone 3 contour generated by the range in the north would not extend off-base. Zone 2 noise contours would extend beyond the proposed installation boundary of both the eastern and western acquisition areas (see Figure 5.4.4-1). However, no existing or planned residential land uses (or other sensitive receptors like schools or medical facilities) were identified within the Zone 2 or 3 contours. The acquisition area is classified by GBSP as Agriculture, which is a compatible use within the Zone 2 and 3 noise contours. Long-term direct impacts to future land use, due to LFTRC noise, would be less than significant.

New utility infrastructure and the access road easements are compatible with the current vacant land use and GBSP Agriculture classification. The new access road would facilitate public access to remote areas. This new access could be considered a potential long-term beneficial and a less than significant impact on adjacent and nearby land use. The landowners may appreciate improved access to their property, but they may also be concerned that a new roadway would facilitate public access.

As addressed in the Cultural Resources and Recreational Resources sections (5.4.10.2 and 5.4.7.2, respectively), Mount Lamlam and Mount Jumullong Manglo public access would not be subject to additional restrictions.
Alternatives 2 and 4 would have a similar level of impact to land use resources due to the loss of public access and valued land uses from the Bolanos Conservation Area. However, the significant impacts are potentially mitigable and would have less of an impact than Alternative 1, which has no mitigation proposed. Both Alternatives (2 and 4) would have a greater impact to land use than Alternative 3, which would have a less than significant impact.

5.4.7 Recreational Resources

5.4.7.1 Affected Environment

Recreational resources within and adjacent to Alternative 4 are the same as those discussed in Section 5.2.7 for Alternative 2.

5.4.7.2 Environmental Consequences

Construction

Construction and/or improvement of access roads on non-federal property would be required to reach the ranges proposed for Alternative 4. The construction impacts would be short-term in nature and would mostly be limited to construction and earth-moving equipment on public roadways slowing access to recreational resources. Although staged construction equipment would not obstruct access to, or the use, of recreational resources, inconveniences to resource seekers (e.g., potential detours, longer waits, and other similar nuisances) would result. However, construction of Alternative 4 would not substantially reduce recreational opportunities, cause substantial conflicts between recreational users, or cause substantial deterioration of recreational resources. Therefore, short-term less than significant impacts to recreational resources would be anticipated.

Operation

The recreational resources and access directly affected by the SDZs include lookout points (Mount Alifan Unit and the Japanese Lookout) and springs (Almagosa and Dobo Springs) located inside of the NAVMAG property (see 2010 Final EIS Volume 2, Chapter 9: Recreational Resources, Section 9.1.5.1: Affected Environment, pages 9-14 to 9-15). In addition to access restrictions, there are potential indirect impacts from firing range noise, which could lessen visitor enjoyment of publicly accessible recreational resources in the area of the LFTRC. However, direct and indirect long-term impacts would be less than significant for the following reasons:

- The 2010 Final EIS states that the impacts are less than significant at the NAVMAG site. Even though the current East/West and L-Shaped NAVMAG LFTRC alternatives extend eastward from NAVMAG and would require land acquisition, there are no identified recreational resources in those areas that would be directly or indirectly affected by land acquisition.

- The construction of the access road for the East/West and L-Shaped NAVMAG LFTRC alternatives would make access to the area easier for the public during those times the ranges are not in operation.

Known recreational resources in the area (primarily Talofofo Falls) would not be impacted by noise during training.
5.4.8 Terrestrial Biological Resources

5.4.8.1 Affected Environment

The proposed LFTRC Alternative 4 would include portions of the lands associated with Alternative 3 (see Section 5.3.8), the non-federal lands associated with the Alternative 2 (see Section 5.2.8), and some additional non-federal lands. These non-federal lands have similar vegetation and habitat types as the areas associated with Alternative 2. Refer to Sections 5.2.8.1 (Alternative 2) and 5.3.8.1 (Alternative 3) for general descriptions of the affected environment in the action area for the proposed L-Shaped ranges. A summary of specific new areas or where differences exist is provided below. For the purposes of the following discussion, the single northernmost range (the proposed MPMG Range) in the northwest portion of NAVMAG will be referred to as the northern portion of the Alternative 4 action area. The remaining proposed ranges associated with Alternative 4 that are located to the southeast of the NAVMAG on non-federal lands will be referred to as the southern portion of the Alternative 4 action area.

Vegetation Communities

Figure 5.4.8-1 depicts the vegetation communities associated with Alternative 4. The vegetation communities were mapped based on the sources described in Sections 5.2.8.1 and 5.3.8.1. The large MPMG Range and the magazine relocation area are within the NAVMAG portion of the L-shaped alternative. The proposed MPMG Range area (which is the same as Alternative 3) contains large areas of primary limestone forest as well as secondary limestone forest (Figure 5.4.8.1). Ravine forest dominates the magazine relocation area.

The remaining proposed ranges are within the southern portion of Alternative 4, which is similar to Alternative 2 in vegetative composition, and is primarily savanna vegetation interspersed with wetland vegetation associated with streams and drainages. Areas of herbaceous wetlands and barren areas (badlands) are also present. The area within the NAVMAG is associated with the SDZs of the proposed ranges and traverses savanna and patches of ravine forest (see Figure 5.4.8-1).

Terrestrial Conservation Areas

The SDZ of the proposed ranges overlies established Overlay Refuge lands within the NAVMAG and the northern portion of the GovGuam Bolanos Conservation Area (see Figure 5.2.8-2). Refer to Section 5.2.8.1 for further details on the Overlay Refuge and Bolanos Conservation Area.

Wildlife - Native Species

The native wildlife discussion in Sections 5.2.8.1 (Alternative 2) and 5.3.8.1 (Alternative 3) are also applicable for this alternative.
Figure 5.4.8-1
Vegetation Communities - NAVMAG (L-Shaped) LFTRC Alternative

Sources: USFS 2006; NAVFAC Pacific 2013a
Special-Status Species: Federal ESA-Listed and Proposed Species

Three ESA-listed species (Mariana fruit bat, Mariana common moorhen, and Mariana swiftlet) and three proposed species (Mariana eight-spot butterfly, *Tabernaemontana rotensis*, and *Cycas micronesica*) occur within the proposed Alternative 4 action area, including the proposed access road (Table 5.4.8-1 and see Figure 5.2.8-3). Further detail on each species can be found in the previous discussions for Alternative 2 (Section 5.2.8) and Alternative 3 (Section 5.3.8). Although “suitable habitat” for special-status species is present within the Alternative 4 project areas, the brown treesnake, the primary factor in the extirpation of special-status wildlife species on Guam and one of the largest obstacles to achieving recovery of special-status species, is still considered abundant and widespread on Guam. Until brown treesnakes are suppressed or removed from at least targeted areas on Guam, the habitat is not in a suitable condition to support the survival of special-status species due to current snake abundance on Guam (e.g., Guam Micronesian kingfisher, Guam rail, Mariana crow) (USFWS 2010a).

**Mariana Fruit Bat.** After 1996, an estimated 5-20 individual Mariana fruit bats were thought to occur within the NAVMAG/Upper Talofofo Watershed, and were assumed to be full time residents of the area, rather than migrants from the main Pati Point Colony on AAFB in northern Guam (Morton and Wiles 2002). USFWS (1996) speculated that disturbance associated with illegal hunting may have inhibited the establishment of a communal roost within the NAVMAG. Currently, fruit bats are only occasionally observed at the NAVMAG. During dawn and dusk observations on 42 different days between February and July 2008, only one bat was sighted along Almagosa Road (Brooke 2008). During 2012 surveys within the northern portion of the Alternative 4 action area for this SEIS, solitary Mariana fruit bats were observed within ravine forest on 6 separate days (Figure 5.4.8-2a) (NAVFAC Pacific 2013a). The sightings were generally within the same area and just north of the Brooke (2008) observation.

Although suitable foraging and roosting habitat occurs within the southern portion of the Alternative 4 action area, particularly within the proposed SDZs within NAVMAG, surveys within and in the vicinity of the proposed range areas on non-federal lands in 2012 did not observe any Mariana fruit bats (NAVFAC Pacific 2013a). As fruit bats are known to travel 6-7.5 miles (10-12 km) to reach forage areas (USFWS 1990), and the proposed southern portion of the Alternative 4 action area contains suitable roosting and foraging habitat (particularly within the SDZ; Figure 5.4.8-2b), there is the potential for fruit bats within NAVMAG to travel to suitable habitat within the southern portion of the Alternative 4 action area. Fruit bat recovery habitat is found within proposed project impacted areas and SDZs associated with Alternative 4 (see Figure 3.8.3-1).

MARIANA COMMON MOORHEN. Although freshwater wetlands were common in the southern portion of the Alternative 4 action area, open water habitat was not observed in the impacted area during 2012 surveys. Stinson et al. (1991) observed four moorhens on a seasonal pond approximately 400 feet (90 m) east of the proposed MRF Range boundary (see Figure 5.2.8-3). During surveys in June 2012, this area was observed to be a dry, well-vegetated, elongated basin several hundred feet long. It is possible some seasonal ponds could be present in very wet periods, but open water would likely be present for only a very short period.

Surveys in 2012 within the Alternative 4 action area documented moorhens on two ponds (see Figure 5.4.8-2a). A single moorhen was observed on 2 separate days on a pond east of the proposed range in the northern portion of the Alternative 4 action area (NAVFAC Pacific 2013a). A single moorhen was also observed on 1 day on a pond located in the southwest corner of the northern range area associated with the proposed MPMG Range.

**MARIANA SWIFTLET.** Swiftlets nest and roost in caves and leave the caves during the day to forage over a wide variety of terrain and vegetation, favoring ridge crests and open grassy areas where they capture small insects while flying (USFWS 1991). There are only three known nesting/roosting caves (Mahlac, Fachi, and Maemong) on Guam for this species and they are located in the northern NAVMAG approximately 2 miles (3.2 km) east of the northern portion of the Alternative 4 action area (see Figure 5.2.8-3).

During June and July 2012, surveys within the southern portion of Alternative 4 range area observed 1-11 Mariana swiftlets at multiple locations from 4 survey stations (see Figure 5.4.8-2b) (NAVFAC Pacific 2013a). All Mariana swiftlet observations were between 1.5 and 2.3 miles (2.4-3.7 km) from the three known nesting/roosting caves in the northeastern portion of NAVMAG.

**MARIANA CROW.** The Mariana crow was last observed in southern Guam in the mid-1960s (USFWS 2005). Since 2009, the population on Guam consisted only of two males on AAFB, occurring primarily within the MSA (USFWS 2009c). However, as of 2012, the Mariana crow is considered extirpated in the wild on Guam (Personal communication via letter from USFWS, Pacific Islands Fish and Wildlife Office, Honolulu, HI regarding the DON NOI for Proposed Placement of LFTRC on Guam NWR; December 7, 2012). The closest population of crows is on the island of Rota, approximately 56 miles (90 km) north of Guam. Crows in northern Guam used primary limestone forest for nesting, with nests exclusively in native trees. They have been observed foraging in both primary and secondary limestone forests and tangantangan (USFWS 2005). Crow recovery habitat is found within proposed project impacted areas and SDZs associated with Alternative 4 (see Figure 3.8.3-1).

**GUAM RAIL.** The Guam rail was last seen in southern Guam in the 1970s, and was extirpated in the wild by 1985. It exists primarily in captivity on Guam and in mainland zoos. Experimental populations of Guam rails were introduced onto Rota, CNMI in 1989 and onto Cocos Island, off the southern coast of Guam, in 2011 (USFWS 2009b; BirdLife International 2013). The Guam rail prefers edge habitats, especially grassy or secondary vegetation areas that provide good cover; mature forest is deemed only marginal for the Guam rail (USFWS 2009b). Rail recovery habitat is found within proposed project impacted areas associated with Alternative 4 (see Figure 3.8.3-2).

**GUAM MICRONESIAN KINGFISHER.** The Guam Micronesian kingfisher was last seen in southern Guam in the 1970s, and was extirpated in the wild by 1988. It is now found only in captivity on Guam and at mainland zoos (USFWS 2008). Kingfishers utilized a wide variety of habitats including primary and secondary limestone forest, strand forest, coconut forest, edge habitats, and forest openings, but mature forests with tree cavities suitable for nesting may be an important requirement for kingfisher reproduction (USFWS 2008). Kingfisher recovery habitat is found within proposed project impacted areas and SDZs associated with Alternative 4 (see Figure 3.8.3-1).
SLEVIN’S SKINK. Originally found on Guam, Cocos Island, Rota, Tinian, Guguan, Alamagan, Asuncion, and Maug, it is now limited to Cocos Island, Sarigan, Guguan, Alamagan, Pagan, and Asuncion. Slevin’s skink has not been recorded on Guam since 1945 and is believed to be extirpated from Guam; it is now known to occur only on Cocos Island (an atoll south of Guam) (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 4 (USFWS 2014b). Therefore, as Slevin’s skink is not found within the impacted areas of Alternative 4, this species is not addressed further.

MARIANA EIGHT-SPOT BUTTERFLY. Although adults, larvae, or eggs of the Mariana eight-spot butterfly were not observed during 2012 surveys within the action area, one large patch and numerous small patches of the host plant Procris pedunculata were observed and mapped within the proposed MPMG Range footprint or 328-foot (100-m) buffers within the northern portion of the Alternative 4 action area (see Figure 5.2.8-3) (NAVFAC Pacific 2013a).

TREE SNAILS. The three proposed endangered tree snail species (Guam tree snail, humped tree snail, and fragile tree snail) were not observed during field surveys conducted within the proposed Alternative 4 action area in 2009 in support of the 2010 Final EIS and in 2012 in support of this SEIS (NAVFAC Pacific 2010, 2013a, 2013b). In 2008, the Guam tree snail was observed 700 feet (210 m) northwest of the proposed magazine relocation area and approximately 3,000 feet (914 m) southeast of the Non-standard Small Arms range area (see Figure 5.2.8-3) (Smith et al. 2008), outside of the Alternative 4 impacted area and SDZ. Therefore, as the tree snail species are not found within the Alternative 4 impacted areas, these species are not addressed further.

SERIANTHES TREE. The endangered Serianthes tree was not observed during field surveys conducted within the proposed Alternative 4 action area in 2009 in support of the 2010 Final EIS and in 2012 in support of this SEIS (NAVFAC Pacific 2010, 2013a, 2013b). The only known location on Guam of the Serianthes tree is on AAFB, more than 20 miles (32 km) north of the NAVMAG. However, Serianthes recovery habitat is found within proposed project impacted areas and SDZs associated with Alternative 4 (see Figure 3.8.3-2).

TABERNAEMONTANA ROTENSIS AND CYCAS MICRONESICA. During 2012 surveys, one area of C. micronesica and one specimen of T. rotensis were observed within the impacted area of the proposed MPMG Range (see Figure 5.2.8-3).

HERITIERA LONGIPEILOTALA. This endemic tree is found in crevices of rough limestone in primary limestone forest (USFWS 2014a). Field surveys for the 2010 Final EIS (NAVFAC Pacific 2010) and in 2012 for this SEIS (NAVFAC Pacific 2013a) did not find H. longipetiolarata within the proposed range areas under Alternative 4. Two locations of H. longipetiolarata are known from the southern portion of the proposed SDZ and one occurrence is just south of the proposed munitions magazine relocation area (see Figure 5.2.8-3). As Heritiera longipetiolarata has not been observed within the impacted areas of Alternative 4, this species is not addressed further.

BULBOPHYLLUM GUAMENSE. An epiphyte in the orchid family, this species occurs in mat-like formations on tree branches of coastal lowland/limestone forests. Currently, there are 8 known occurrences on Guam totaling fewer than 250 individuals (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 4 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as B. guamense is not found within the impacted areas of Alternative 4, this species is not addressed further.

EUGENIA BRYANII. A perennial shrub in the myrtle family, the species is known only from the island of Guam. Historically, E. bryanii is known from windy exposed coastal clifflines and along the Pigua River,
in lowland/limestone forests. Currently, *E. bryanii* is known from 6 occurrences totaling fewer than 420 individuals (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 4 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *E. bryanii* is not found within the impacted areas of Alternative 4, this species is not addressed further.

**Maesa Walkeri.** A shrub or small tree in the primrose family typically found in limestone forests, this species is known from only two individuals on Guam, one of which is located along the southwestern border of the NAVMAG (Figure 5.2.8-3) (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 4 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *M. walkeri* is not found within the impacted areas of Alternative 4, this species is not addressed further.

**Nervilia Jacksoniae.** A small herb in the orchid family, this species is found in lowland/limestone forests. On Guam, *N. jacksoniae* is known from 2 occurrences totaling fewer than 200 individuals (USFWS 2014). There are no records of the species within the impacted areas of Alternative 4 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *N. jacksoniae* is not found within the impacted areas of Alternative 4, this species is not addressed further.

**Psychotria Malaspinae.** A shrub or small tree in the coffee family, this species is found in lowland/limestone forests. Currently, *P. malaspinae* is known from 5 occurrences: 1 individual at Ritidian Point within the Guam NWR, 1 individual at Pågat Point, 1 individual at the base of Mt. Almagosa, and 2 individuals at NWF (USFWS 2014a, 2014b). None of these individuals have been observed within the last 5 years (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 4 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *P. malaspinae* is not found within the impacted areas of Alternative 4, this species is not addressed further.

**Solanum Guamense.** A small shrub in the nightshade family that occurs within limestone forests. Currently, *S. guamense* is known from a single occurrence of one individual on Guam (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 4 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *S. guamense* is not found within the impacted areas of Alternative 4, this species is not addressed further.

**Tinospora Homosepala.** A vine in the moonseed family found in limestone forests. Currently, *T. homosepala* is known from 3 occurrences totaling approximately 300 individuals (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 4 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *T. homosepala* is not found within the impacted areas of Alternative 4, this species is not addressed further.

**Tuberolabium Guamense.** An epiphyte in the orchid family found in limestone forests. Currently, *T. guamense* is known from 3 occurrences on Guam: 2 occurrences within the NAVMAG (1 occurrence in the forest ecosystem of the Mt. Almagosa cliffline and 1 south of the swiftlet caves) (see Figure 5.2.8-3) and 1 at Finegayan (NAVFAC Pacific 2010; USFWS 2014a, 2014b). There are no records of the species within the impacted areas of Alternative 4 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *T. guamense* is not found within the impacted areas of Alternative 4, this species is not addressed further.

**Dendrobium Guamense.** An epiphyte in the orchid family, the species occurs within lowland/limestone forests and savanna. On Guam, there are 4 occurrences totaling fewer than 250 individuals (USFWS 2014a). There is 1 known occurrence within the NAVMAG within the vicinity of Almagosa Springs (see Figure 5.2.8-3). There are no records of the species within the impacted areas of Alternative 4 (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 4 (USFWS 2014).
Therefore, as *D. guamense* is not found within the impacted areas of Alternative 4, this species is not addressed further.

**Hedyotis Megalantha.** A perennial herb in the coffee family, this species occurs in savanna areas in southern Guam. Currently, *H. megalantha* is known from one large scattered occurrence totaling fewer than 1,000 individuals on southern Guam, between Mt. Alutom and Tarzan Falls. This species typically occurs as lone individuals rather than in patches or groups (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 4 (USFWS 2014b). Therefore, as *H. megalantha* is not found within the impacted areas of Alternative 4, this species is not addressed further.

**Phyllanthus Saffordii.** This woody shrub is currently known from four scattered occurrences on southern Guam within savanna areas: Mt. Alutom, Piti Hills, Nimitz Hill “War in the Pacific Lookout,” and near the Cetti Bay Watershed (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 4 (USFWS 2014b). Therefore, as *P. saffordii* is not found within the impacted areas of Alternative 4, this species is not addressed further.

**Cyathea Lunulata.** Field surveys for the 2010 Final EIS (NAVFAC Pacific 2010) and in 2012 for this SEIS (NAVFAC Pacific 2013a) did not find the tree fern *C. lunulata* within the proposed range areas under Alternative 4. As the tree fern has not been observed within the impacted areas associated with Alternative 4, this species is not addressed further.

**Merrilliodendron Megacarpum.** During 2012 surveys, several small patches of *M. megacarpum* was observed within the northern impacted area of Alternative 4 (Figure 5.2.8-3). *M. megacarpum* is considered an SOGCN because of its rarity and potential threats from ungulate damage, typhoons, development, and insect infestation (GDAWR 2006). *M. megacarpum* also is present in large patches within primary limestone forest in the west-central area of the SDZs (see Figure 5.2.8-3).

5.4.8.2 Environmental Consequences

**Construction**

**Vegetation.** The construction of the ranges and access road on NAVMAG and non-federal lands under Alternative 4 would impact areas dominated by savanna (172 acres [70 ha]), with an additional 130 acres
(53 ha) of limestone forest, 101 acres (41 ha) of developed/barren areas, 62 acres (25 ha) of ravine forest, 19 acres (8 ha) of herbaceous scrub, and 7 acres (3 ha) of wetlands, and 7 acres (3 ha) of agricultural land (see Figure 5.4.8-1 and Table 5.4.8-2).

Legend: PLF = primary limestone forest; SLF = secondary limestone forest; RF = ravine forest; HW = herbaceous wetland; HS = herbaceous scrub; Sav = savannah; Dev/Bar = developed/barren; Ag = agriculture.

Based on surveys conducted in 2012 in the proposed range areas, the ravine forest community is significantly degraded in many areas due to invasion by non-native woody species including *Vitex* and betelnut palm, and heavy infestation by herbaceous non-native invasive plants (NAVFAC Pacific 2013a). Impacts to vegetation from construction of the proposed HG Range at Andersen South were discussed in Section 5.1.8.2 and were found to be less than significant.

Native limestone forest, both primary and secondary, has been significantly reduced on Guam due to past and ongoing actions including extensive disturbance during and after WWII, widespread planting of non-native species; and impacts from non-native ungulates; development; fire; and deforestation. As stated in Section 3.8.1.1, limestone forests on Guam are important since they retain the functional ecological components of native forest that provide habitat for the majority of Guam’s native species, including ESA-listed, ESA-proposed, and Guam-listed species, and Guam SOGCN, as well as quality and reducing fire risk. Non-native forest communities (e.g., tangantangan, *Vitex*) significantly alter the forest structure, composition, and resilience to other disturbance processes and do not provide the conditions suitable for native flora and fauna species to persist (Morton et al. 2000; GDAWR 2006; Guam Department of Agriculture 2010; JRM 2013).

Of the 18,538 acres (7,502 ha) of primary and secondary limestone forest found on Guam, approximately 13,110 acres (5,305 ha) are found primarily within AAFB, Finegayan, and NAVMAG (USFS 2006). Under Alternative 4, 67 acres (27 ha) of primary limestone forest, 63 acres (26 ha) of secondary limestone forest, and 62 acres (25 ha) of ravine forest would be removed (see Table 5.4.8-2). Ravine forest is also an important community type for native species in southern Guam. Therefore, given the importance of limestone and ravine forest habitats for native species and the continuing loss of native forests across Guam, the conversion of 193 acres (78 ha) of limestone and ravine forest on NAVMAG to developed area would be a significant but mitigable impact to the regional vegetation community and its function.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct, long-term impacts of proposed construction activities on vegetation communities with implementation of Alternative 4. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.
Potential Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the contractor education program.
- **Onsite Vegetation Waste Management Procedures.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the vegetation waste management procedures.
- **DON Guam Landscaping Guidelines.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of landscaping guidelines.
- **LFTRC Range Berm Controls.** To manage stormwater runoff and control erosion, LFTRC range berms would contain native or non-invasive herbaceous vegetation and other engineering controls.
- **Contractor Plans and Specifications.** All construction would occur within the limits of construction shown in the project figures.

Potential Mitigation Measures

To mitigate for significant impacts to limestone forest, the DON proposes to implement forest enhancement on a minimum of 193 acres (78 ha) of limestone and ravine forest. Forest enhancement would include but is not limited to the following actions:

- Ungulate management consisting of exclusion fencing and active control (i.e. trapping, snaring, shooting) with the goal of eradication within the fenced areas.
- Non-native, invasive vegetation removal.
- Propagation, planting, and establishment of native species that are characteristic of native limestone forest habitats (e.g., *A. mariannensis*, *G. mariannae*, *F. prolixa*, *M. citrifolia*, *W. elliptica*).

The degradation and loss of primary limestone and other forest habitats resulting from ungulate damage and invasion by alien plant species has substantially diminished the extent of habitat for native species in the Mariana archipelago. The anticipated benefit of implementing these potential mitigation measures is improved habitat quality for native flora and fauna, including special-status species. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

**Terrestrial Conservation Areas.** The only terrestrial conservation area within the impacted areas of Alternative 4 is Overlay Refuge. Overlay Refuge lands were established for the purpose of conserving and protecting ESA-listed species and other native flora and fauna, maintaining native ecosystems, and the conserving native biological diversity, recognizing that the primary purpose of lands within the Overlay Refuge is to support the national defense missions of the Navy and Air Force.

Approximately 219 acres (88 ha) of Overlay Refuge lands (Table 5.4.8-3), or 1% of the total Overlay Refuge lands on Guam, would be directly impacted under Alternative 4. This area overlaps with the vegetation communities discussed previously. The majority (102 acres [41 ha]) is comprised primarily of limestone forest (Table 5.4.8-3). Therefore, because proposed construction activities would convert 219 acres (88 ha) of Overlay Refuge lands to developed areas, this would be a significant loss to the
conservation function of these lands and implementation of Alternative 4 would result in significant but mitigable impacts to terrestrial conservation areas.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct, long-term impacts of proposed construction activities on terrestrial conservation areas with implementation of Alternative 4. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

The same BMPs discussed above under *Vegetation* would be implemented for terrestrial conservation areas.

**Potential Mitigation Measures**

To mitigate for significant impacts to terrestrial conservation areas, the DON would submit a proposal to CNO Energy and Environmental Readiness Division to designate an ERA on the NAVMAG to conserve native limestone forest in southern Guam which provides habitat for special-status species. The DON has defined an ERA as a physical area or biological unit in which current natural conditions are maintained insofar as possible. These conditions are ordinarily achieved by allowing natural, physical, and biological processes to prevail without human intervention. However, under unusual circumstances, deliberate manipulation (e.g., removal or control of invasive species) may be utilized to maintain the unique feature that the ERA was established to protect (NAVFAC 1996). The proposed NAVMAG ERA would encompass approximately 553 acres (234 ha). Although the proposed NAVMAG ERA is currently part of the Overlay Refuge, implementation of these potential mitigation measures would provide an increased level of protection by further ensuring this area is maintained in natural and near natural conditions and to have available such areas for research and scientific manipulation (NAVFAC 1996; NAVFAC Marianas 2010).

In addition, the DON proposes to submit a proposal to CNO Energy and Environmental Readiness Division to expand the existing Orote ERA by approximately 32 acres (13 ha) of terrestrial habitat. The Final Orote ERA Expansion proposal was completed FY 2013 and will be submitted for approval in 2014.

**Wildlife - Native Species.** Short-term construction noise may temporarily impact suitable habitat for native birds in the vicinity of the construction areas, but they would relocate to other areas of suitable habitat in the vicinity, and could return to the area following construction. Non-listed native reptiles are abundant throughout Guam and impacts to vegetation communities under Alternative 4 would result in less than significant impacts to non-listed native reptile populations. Implementation of Alternative 4 would not
have a significant adverse effect on a population of any migratory bird species or other native wildlife species. Impacts to wildlife from the construction of the HG Range at Andersen South were discussed in Section 5.1.8.2 and impacts would be less than significant.

Therefore, as presented above, long-term, direct impacts to populations of native wildlife species would not result because these species are abundant in surrounding areas and could repopulate portions of suitable habitat within the affected area after construction. Therefore, direct impacts to native wildlife species would be less than significant with implementation of proposed construction activities associated with Alternative 4.

Proposed construction activities and associated movement of materials onto and off of Guam could increase the potential for the spread of existing or introduction of new non-native invasive species. To prevent the inadvertent spread of non-native species on Guam or to other locations off of Guam, the DON would implement standard biosecurity measures (e.g., HACCP, brown treesnake interdiction measures, coconut rhinoceros beetle vegetation management procedures, and outreach/education) into construction protocols, procedures, and activities.

The following BMPs would be implemented to avoid and minimize potential direct, long-term impacts of proposed construction activities on native wildlife with implementation of Alternative 4.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

With implementation of these BMPs, including development of HACCP plans and ongoing implementation of standard DON biosecurity protocols regarding detection and management of non-native species (e.g., coconut rhinoceros beetle), the potential for the introduction of new or spread of existing non-native species on Guam is substantially reduced. Therefore, there would be less than significant impacts to native wildlife species related to the potential introduction and establishment of non-native species with implementation of proposed construction activities associated with Alternative 4.

Damage of forested areas, particularly primary and secondary limestone forests, by non-native ungulates (i.e., deer, pigs) is a serious concern on Guam. Under Alternative 4, removal of large amounts of limestone forest currently used by ungulates would displace and concentrate ungulates into adjacent areas, resulting in even higher densities and potentially greater habitat damage. Potential impacts from changes in ungulate densities from construction projects within the same or similar habitat areas as proposed in this SEIS were addressed in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.2.1: North, page 10-115).

The implementation of the potential mitigation measures under the Vegetation section above would also benefit native wildlife species. In particular, the objectives of ungulate management,
control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures.

Special-Status Species: Federal ESA-Listed and Proposed Species

Impacts to special-status species from the construction of the HG Range at Andersen South were discussed in Section 5.1.8.2 and were determined to be less than significant. The following discussion addresses those species that occur within the Alternative 4 action area.

MARIANA FRUIT BAT. Approximately 161 acres (65 ha) of Mariana fruit bat recovery habitat would be removed due to proposed construction activities at NAVMAG under Alternative 4. This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

Additional potential direct temporary impacts to the Mariana fruit bat from construction activities are based on the distances from those activities that are likely to cause disturbance to this species (e.g., noise, human activity, lighting). The evaluation of fruit bat disturbance is based on the approach used by USFWS in previous ESA section 7 formal consultations and associated BOs (e.g., USFWS 2006b, 2010). These distances are: roosting habitat within 492 feet (150 m) and foraging habitat within 328 feet (100 m) from the activity (Wiles, personal communication 2006 and Janeke, personal communication 2006, respectively, as cited in USFWS 2006b).

The species is currently limited to the few areas on Guam away from human activities and with suitable habitat, primarily on federal lands on the NAVMAG and AAFB (JRM et al. 2012a, 2012b; JRM 2013; A. Brooke, NAVFAC Marianas, personal communication). However, illegal hunting, loss and degradation of native forest, predation by the brown tree snake, and the increased extirpation risk owing to the high vulnerability of very small populations continue to limit the potential recovery of the species on Guam (USFWS 2010; JRM 2013). Based on the equilibrium/carrying capacity of snakes on Guam (Rodda and Savidge 2007), implementation of the proposed action is not expected to increase the likelihood of predation by the brown tree snake on Mariana fruit bats.

Although the loss of 161 acres (65 ha) of fruit bat recovery habitat on Guam would not preclude the recovery or survival of the fruit bat, it would reduce the total number of bats that the island can support. Given this loss of recovery habitat and the critically low numbers of bats on Guam, there would be significant but mitigable impacts to the Mariana fruit bat.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct long-term impacts of proposed construction activities on Mariana fruit bats with implementation of Alternative 4. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Pre-Construction Surveys.** Surveys would be completed within suitable fruit bat habitat 1 week prior to onset of construction activities following the USFWS-approved JRM protocol.
If a fruit bat is present within 492 feet (150 m) of the project site, the work must be postponed until the bat has left the area.

- **Lighting Installation.** Lighting would be designed to meet minimum safety and AT/FP requirements. Hooded lights would be used to the maximum extent practicable at all new roads and facilities adjacent to fruit bat habitat. Illumination of forest would be kept to an absolute minimum.

**Potential Mitigation Measures**

The same potential mitigation measures discussed previously under Vegetation (i.e., forest enhancement of 193 acres [78 ha] of limestone forest) would be applicable for the Mariana fruit bat and its recovery habitat. The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Mariana fruit bat. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

**Mariana Swiftlet.** Although the only swiftlet nest/roost caves are approximately 1 mile (1.6 km) east of the proposed northern portion of the Alternative 4 action area, surveys in 2008, 2009, and 2012 did not observe any Mariana swiftlets within the area of the northern portion of Alternative 4. Based on surveys for this SEIS as well as observations from other survey efforts, swiftlets appear to forage to the north, east and south of the caves (Morton and Amidon 1996; NAVFAC Pacific 2010, 2013a, 2013b; R. Spaulding, Cardno TEC, unpublished data).

Based on 2012 field surveys, this species forages in the proposed southeastern portion of the Alternative 4 action area, particularly in the northern area, closer to the only known swiftlet nesting/roosting caves on Guam. Swiftlets would continue to forage within the extensive foraging habitat surrounding the proposed southeastern range area of Alternative 4, including the extensive areas of savanna and ravine forest to the north, west, and east of the proposed range areas, and areas in the vicinity of the nest/roost caves on NAVMAG and the drainages of the Mahlac, Maagas, and Talofofo rivers (see Figures 5.2.8-1 and 5.2.3-3). The proposed construction activities would also not impact regional insect populations that are the prey base for the swiftlet. Although noise levels within the immediate vicinity of proposed construction activities would increase, they would be localized and temporary. Proposed construction activities would not impact the swiftlet nesting/roosting caves approximately 1 mile (1.6 km) east of the northern range and 2 miles (3.2 km) north of the proposed southeastern ranges associated with Alternative 4. Therefore, there would be less than significant impacts to the Mariana swiftlet with implementation of the proposed range construction activities under Alternative 4.

**Mariana Crow.** The Mariana crow is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the crow is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the crow, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the crow is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative 4, impacts to the crow would be limited to recovery prospects. If crows are reintroduced and exposed to construction activities under Alternative 4, they may be disturbed (DON 2014).

Although the crow no longer occurs on Guam, approximately 166 acres (67 ha) of crow recovery habitat would be removed due to proposed construction activities under Alternative 4. This area is included in the
impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

Although this loss of crow recovery habitat on Guam would not preclude the recovery of the crow should it be reintroduced to Guam in the future, it would reduce the total number of crows that the island can support. If and when the crow is reintroduced to Guam, the best available information indicates project-related noise would not further reduce the amount of recovery habitat suitable for this species’ breeding, feeding and sheltering (USFWS 2010). Given this loss of recovery habitat, there would be significant but mitigable impacts to the recovery of the Mariana crow.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct long-term impacts of proposed construction activities on the recovery of the Mariana crow with implementation of Alternative 4. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.

- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.

- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

**Potential Mitigation Measures**

- **Brown Treesnake Suppression or Eradication.** See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW for a detailed description of the brown treesnake suppression or eradication program.

- The same potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 193 acres [78 ha] of limestone forest) would be applicable for the Mariana crow and its recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Mariana crow, should it be reintroduced to Guam in the future.

**GUAM RAIL.** The Guam rail is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the rail is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the rail, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the rail is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative 4, impacts to the rail would be limited to recovery prospects. If rails are reintroduced and exposed to construction activities under Alternative 4, they may be disturbed (DON 2014).
Although the rail no longer occurs on Guam, approximately 50 acres (20 ha) of rail recovery habitat within the proposed magazine relocation area would be removed due to proposed construction activities under Alternative 4. This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

This loss of rail recovery habitat on Guam would not preclude the recovery or survival of the rail should it be reintroduced to Guam in the future, and it would not substantially reduce the total number of rails that the island can support. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to the Guam rail with implementation of proposed construction activities associated with Alternative 4.

The following BMPs may be implemented to avoid and reduce potential long-term impacts of proposed construction activities on the recovery of the Guam rail with implementation of Alternative 4.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

In addition, potential mitigation measures proposed above for vegetation and the Mariana crow would benefit the Guam rail.

- **Brown Treesnake Suppression or Eradication.** See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW for a detailed description of the brown treesnake suppression or eradication program.
- The same potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 193 acres [78 ha] of limestone forest) would be applicable for the rail and its recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Guam rail, should it be reintroduced to Guam in the future.

**GUAM MICRONESIAN KINGFISHER.** The kingfisher is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the kingfisher is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the kingfisher, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the kingfisher is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative 4, impacts to the kingfisher would be limited to recovery prospects. If kingfishers are reintroduced and exposed to construction activities under Alternative 4, they may be disturbed (DON 2014).
Although the kingfisher no longer occurs on Guam, approximately 161 acres (65 ha) of kingfisher recovery habitat would be removed due to proposed construction activities under Alternative 4. This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

Although this loss of kingfisher recovery habitat on Guam would not preclude the recovery of the kingfisher should it be reintroduced to Guam in the future, it would reduce the total number of kingfishers that the island can support. Given this loss of recovery habitat, there would be significant but mitigable impacts to the recovery of the Guam Micronesian kingfisher.

The following BMPs and potential mitigation measures may be implemented to avoid, minimize, and mitigate potential direct and indirect long-term impacts of proposed construction activities on the recovery of the Guam Micronesian kingfisher with implementation of Alternative 4. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

**Potential Mitigation Measures**

- **Brown Treesnake Suppression or Eradication.** See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW for a detailed description of the brown treesnake suppression or eradication program.
- The same potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 193 acres [78 ha] of limestone forest) would be applicable for the rail and its recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Guam rail, should it be reintroduced to Guam in the future.

**MARIANA COMMON MOORHEN.** Seasonal and permanent wetlands/ponds that provide suitable habitat for moorhens (i.e., open water) are limited on Guam and the lack of sufficient wetland areas is a limiting factor in the recovery of the species. In 1991 and 2004, there were an estimated 22 seasonal or permanent wetlands on Guam that were utilized by moorhens (Stinson et al. 1991; Takano and Haig 2004a). Most wetlands used by moorhens on Guam, with the exception of Fena Reservoir, are less than 1.5 acres (0.6 ha) in size. Identifying essential wetlands and site fidelity are especially important since wetland habitat is increasingly very limited on Guam. Because most of the large natural wetlands are overgrown with persistent vegetation and dense monocultures of *P. karka*, moorhens are increasingly left with fewer and fewer wetlands to choose from, particularly at the onset of the dry season when seasonal wetlands begin to dry up (Stinson et al. 1991; Takano and Haig 2004a, 2004b).
Implementation of Alternative 4 would directly impact and remove one pond that is known to be used by 1-2 moorhens. The loss of one temporary wetland under Alternative 4 would be a less than significant impact to the Mariana common moorhen.

MARIANA EIGHT-SPOT BUTTERFLY. Although adults, larvae or eggs of the eight-spot butterfly have not observed within the Alternative 4 action area, host plants have been observed within the proposed MPMG Range in the northern portion of the Alternative 4 action area (see Figure 5.2.8-3). With implementation of appropriate BMPs to avoid and minimize potential impacts to eight-spot butterflies (e.g., pre-construction butterfly and host plant surveys within the proposed range areas and salvage/relocation of host plants; see Section 2.6), there would be less than significant impacts to the Mariana eight-spot butterfly with implementation of proposed construction activities under Alternative 4. In addition, implementation of the potential mitigation measures described above under Vegetation (i.e., forest enhancement of 193 acres [78 ha] of limestone forest) would also benefit the survival the eight-spot butterfly. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species, including eight-spot butterfly host plants.

SERIANTHES TREE. Although individual Serianthes trees do not occur within the impacted areas of Alternative 4, approximately 19 acres (8 ha) of Serianthes recovery habitat would be removed due to proposed construction activities. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

This loss of Serianthes recovery habitat on Guam would not preclude the recovery of Serianthes, and it would not substantially reduce the total number of Serianthes that the island can support. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to Serianthes with implementation of proposed construction activities associated with Alternative 4.

The following BMPs may be implemented to avoid and minimize, potential direct long-term impacts of proposed construction activities on the recovery of Serianthes with implementation of Alternative 4.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.

The implementation of the potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 193 acres [78 ha] of limestone forest) would benefit Serianthes habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

TABERNAEMONTANA ROTENIS AND CYCAS MICRONESICA. An individual *T. rotensis* and an area of *C. micronesica* were observed within the footprint of the proposed MPMG Range (see Figure 5.2.8-3). Under Alternative 4, all *T. rotensis* and *C. micronesica* would be avoided to the maximum extent practicable during proposed construction activities. In addition, high-value (both biologically and culturally) plant species, such as *T. rotensis* and *C. micronesica* would be salvaged to the maximum extent practicable during construction activities and translocated to suitable habitat (see Section 2.8).
Therefore, with implementation of the previously mentioned BMPs (e.g., avoidance, or salvage and translocation), there would be less than significant impacts to *T. rotensis* and *C. micronesica* with implementation of the proposed construction activities associated with Alternative 4.

**Special-Status Species: Guam-Listed and SOGCN**

**PACIFIC SLENDER-TOED GECKO.** The Pacific slender-toed gecko is listed by Guam as endangered. This species is threatened primarily by introduced species (e.g., feral ungulates, curious skinks, musk shrews, rats, brown treesnakes, and feral cats) and loss of limestone forest habitat. The gecko is known from primary and secondary limestone forest in the Alternative 4 impacted area of the proposed MPMG Range (see Figure 5.2.8-3). The full extent of the distribution and abundance of this species throughout Guam has not been assessed. The loss of approximately 193 acres (78 ha) of occupied gecko habitat with implementation of construction activities under Alternative 4 would be a significant but mitigable impact to the Pacific slender-toed gecko.

The following BMPs and potential mitigation measures may be implemented to avoid, minimize, and mitigate potential direct long-term impacts of proposed construction activities on the slender-toed gecko with implementation of Alternative 4. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

**Potential Mitigation Measures**

The potential forest enhancement mitigation measures described above in the Vegetation section would also result in a conservation benefit to the Pacific slender-toed gecko. The proposed brown treesnake research and suppression may also benefit this species. See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW potential mitigation discussion for more information.

**MERRILLIODENDRON MEGACARPUM.** Areas of *M. megacarpum* were observed within the footprint of the proposed MPMG Range (see Figure 5.2.8-3). Under Alternative 4, all *M. megacarpum* would be avoided to the maximum extent practicable during proposed construction activities. In addition, high-value (both biologically and culturally) plant species, such as *M. megacarpum*, would be salvaged to the maximum extent practicable during construction activities and translocated to suitable habitat (see Section 2.8). Therefore, with implementation of the previously mentioned BMPs (e.g., avoidance, or salvage and translocation), there would be less than significant impacts to *M. megacarpum* with implementation of the proposed construction activities associated with Alternative 4.

**Operation**

*Vegetation.* With implementation of BMPs (see previous discussion of construction impacts under Vegetation), including ongoing implementation of standard DON and commercial biosecurity protocols (e.g., Port of Guam, A.B. Won Pat International Airport) regarding detection and management of non-native species, invasive species outreach and education, applicable elements of the SIP, and 1-year post construction monitoring to evaluate effectiveness of HACCP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of Alternative 4 is considered unlikely.
Fire potential would increase due to proposed live-fire range operations. Fire can result in direct effects to vegetation by increasing erosion, allowing for the establishment of non-native species, and altering wildlife habitat by reducing food resources, breeding habitat, and shelter. Native plants and their habitats on Guam are adapted to a humid, tropical climate and are not adapted to a fire driven ecosystem (USFWS 2008a). Fire is a serious problem on Guam. Fire history records available from 1979 - 2002 indicate that over this 23-year period more than 16,000 fires have occurred in Guam (averaging more than 700 per year) that have burned in excess of 100,000 acres (40,469 ha), primarily in southern Guam. Of these 16,000 fires, 477 of them occurred on Naval Base Guam, primarily at Apra Harbor and NAVMAG, burning more than 9,800 acres (3,966 ha) (Nelson 2008).

As a BMP and in accordance with range safety protocols, a Range Fire Management Plan would be prepared, based on the DON’s Wildland Fire Management Plan (Nelson 2008) (see Section 2.8). It would include protocols for monitoring fire conditions and adjusting training as needed (e.g., certain types of training may be disallowed under certain fire conditions), and location and management of firebreaks, fire-fighting roads, and a fire fighting water system. Units undergoing training would be briefed on requirements suitable to the conditions of the day and protocols should a fire occur (e.g., specifying how the range would shut down and how fire suppression action would be taken). With implementation of the Range Fire Management Plan, which establishes management and fire suppression and emergency response procedures, potential impacts from range-related wildfires would be less than significant. The USFWS concluded in their BO for the 2010 Final EIS that they anticipated that no additional vegetation would be lost due to wildfires igniting as a result of proposed live-fire training operations (USFWS 2010a). Therefore, there would be less than significant impacts to vegetation from operation of LFTRC Alternative 4.

Terrestrial Conservation Areas. Impacts to terrestrial conservation areas from the operation of the HG Range at Andersen South were discussed in Section 5.1.8.2. As Andersen South does not contain any terrestrial conservation areas, there would be no impacts.

Modeled noise levels greater than 55 dBA ADNL from proposed live-fire range operations would overlie approximately 1,525 acres (617 ha) of Overlay Refuge lands and the Bolanos Conservation Area (Table 5.4.8-4 and Figures 5.4.8-2a and 5.4.8-2b). Overlay Refuge lands were established for the purpose of conserving and protecting ESA-listed species and other native flora and fauna, maintaining native ecosystems, and the conserving native biological diversity, recognizing that the primary purpose of lands within the Overlay Refuge is to support the national defense missions of the Navy and Air Force.

Although there would be an increase in noise associated with LFTRC activities within the northern NAVMAG, the proposed noise-generating activities would not result in a loss of the conservation function of Overlay Refuge lands and support of the national defense missions of the Navy and Air Force at the NAVMAG. While the modeled noise levels from proposed range operations may be heard within the southern portion of NAVMAG on Overlay Refuge lands and within the northern portion of the Bolanos Conservation Area (see Figure 5.4.8-2b), the noise levels would be approximately 55-64 dBA ADNL or less and would be barely perceptible above ambient noise levels for the region (see Section 5.2.4, Noise). Signs would be posted along the perimeter of the SDZ notifying the public of an active live-fire range within the area behind the signs and access is restricted during operations. The Bolanos...
Conservation Area is remote, difficult to access, limited to use by hikers and hunters, and management is minimal (GDAWR 2006). Therefore, there would be less than significant impacts to management or conservation values of terrestrial conservation areas with implementation of Alternative 4.

Wildlife - Native Species. Operational impacts to native wildlife would include an increase in noise and lighting. These potential impacts were evaluated in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.2.2: Central, page 10-129) for a similar proposed action, and were found to be not significant. With implementation of BMPs (see previous discussion of construction impacts under Vegetation), including ongoing implementation of standard DON and commercial biosecurity protocols (e.g., Port of Guam, A.B. Won Pat International Airport) regarding detection and management of non-native species, invasive species outreach and education, applicable elements of the SIP, and 1-year post-construction monitoring to evaluate effectiveness of HACCP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of the proposed LFTRC under Alternative 4 is considered unlikely. The DON recognizes the USFWS’ ongoing concern regarding potential spread of the brown treesnake. The DON will consult with USFWS under ESA section 7 to determine if additional brown treesnake interdiction measures are warranted and applicable. In addition, lighting associated with the range and support areas would be hooded or shielded to the maximum extent practicable to prevent unnecessary light beyond operational areas. Therefore, there would be less than significant impacts to native wildlife with operation of the proposed LFTRC under Alternative 4.

Special-Status Species: Federal ESA-Listed and Proposed Species

MARIANA FRUIT BAT. The assessment of noise levels associated with the proposed HG Range at Andersen South was previously discussed in Section 5.1.8.2. There would be no impacts to Mariana fruit bats from noise associated with operation of the HG Range.

For those species of fruit bats that have been tested for hearing sensitivity, their audiograms are very similar to those of humans, with similar upper and lower frequency limits and hearing threshold levels (Calford et al. 1995; Koay et al. 1998; Heffner et al. 2006). Therefore, it is likely that noise from live-fire operations at the proposed ranges would be heard by fruit bats as it would be heard by humans.

The USFWS established 60 dB and 93 dB as two thresholds of biological significance based on their review of impacts of noise to wildlife. Noise levels above 60 dB have been found to affect acoustic communication, breeding biology, survival of young, and non-auditory bird and mammal physiology. Noise levels above 93 dB may temporarily or permanently affect hearing (USFWS 2010a). No species would be exposed to noise levels of 93 dB or greater under the proposed action. While noise levels may approach 93 dB in the immediate vicinity of the firing of an individual weapon, fruit bats or other wildlife species would not be in proximity to the live-fire event given the location and nature of weapons firing within a developed range area.

Responses to noise can vary among individuals as a result of habituation where after a period of exposure to a stimulus, an animal stops responding to the stimulus. In general, a species can often habituate to human-generated noise when the noise is not followed by an adverse impact. Even when a species appears to be habituated to a noise, the noise may produce a metabolic or stress response (increased heart rate results in increased energy expenditure) though the response may or may not lead to changes in overall energy balance. Anthropogenic noise disturbance is known to alter animal behavioral patterns and lead to population declines (Barber et al. 2011; Francis and Barber 2013; McGregor et al. 2013).
In addition to noise level, the frequency and regularity of the noise also affect species sensitivity. That is, different types of noise sources will produce different effects on different species. Noise from aircraft overflights may not produce the same response from a wildlife species as noise from a land-based noise source such as a vehicle, chainsaw, or gun shot. Wildlife species often do not react only to a noise source but more importantly to the visual component associated with that noise source. Nesting birds will react to a noise source by tilting their head, becoming alert, etc. but often do not leave the nest or perch until there is a visual connection with the noise source. For example, birds may not react to just the sound of a chainsaw, but when that sound is coupled with a human walking near the bird, the bird will flush. This is also shown in reactions by various species to aircraft overflights (airplanes and helicopters). An overflight with just a sound component does not elicit a strong response, but if an animal hears and then sees the aircraft, the bird will more likely flush and move away (Manci et al. 1988; USFWS 1992; Krausman et al. 1993; Bowles 1995). In other words, human intrusions near roost sites, nests, foraging areas, etc. (e.g., timber harvesting, hiking, hunting) are readily detectable and substantial (USFS 1992).

Species that are commonly hunted often demonstrate behavioral (e.g., flushing, startle response) or physiological responses (e.g., increased heart rates, increased respiration rates) to gunshot sounds (Larkin et al. 1996). Knight et al. (1987) found that American crows nesting in urban areas were less wary of people than American crows nesting in rural habitat and attributed the difference to the hunting of rural crows. Barron et al. (2012) found that American crows avoided areas with live-fire exercises in a similar fashion and suggested that species hunted by humans will be more adversely affected by human activity, including military training (e.g., live-fire training) than species that are not hunted.

As stated by Morton and Wiles (2002), “Poaching is a particularly insidious activity because not only does it impact fruit bats through mortality, it reinforces behavioral avoidance of humans. Consequently, roosting or foraging fruit bats that might not otherwise be disturbed by some human activities … may become unduly sensitized to them because of illegal hunting.” Based on observations on Guam and Rota, fruit bats have abandoned areas where hunting has occurred and did not return even though no further hunting or gunshots occurred within the area for months after (Janeke 2006; AAFB 2008b; USFWS 2009a; Mildenstein and Mills 2013). In addition, anecdotal evidence from numerous individuals who have conducted fruit bat research on Guam and the CNMI for many years indicate that fruit bats do avoid areas that have been previously subjected to hunting and also areas that experience live-fire activities (G. Wiles, Washington Department of Fish and Wildlife, personal communication, 2014; T. Mildenstein, University of Montana, personal communication, 2014; D. Janeke, HDR, Inc., personal communication, 2014; N. Johnson, Marinas Conservation Unlimited, personal communication, 2014). For example, during fruit bat monitoring at AAFB near the CATM range as part of a larger study monitoring the effects of aircraft overflights on fruit bats and crows (JRM et al. 2012b), N. Johnson observed flying fruit bats avoid the CATM range by 300-400 m when live-fire operations were being conducted (N. Johnson, Marinas Conservation Unlimited, personal communication, 2014).

However, a species can also habituate to human-generated noise when the noise is not followed by an adverse impact. While fruit bats may avoid an area subjected to hunting and the associated gun shots, fruit bats, like most wildlife species, will also learn that if a disturbance or sound does not produce an adverse effect (e.g., mortality), then they can habituate to that disturbance or sound and will not show an adverse reaction (e.g., flying away, avoiding the area) (Boyle and Samson 1985; Francis and Barber 2013).

Most of the effects of noise are mild enough that they may never be detectable as variables of change in population size or population growth against the background of normal variation (Bowles 1995). Other environmental variables (e.g., predators, weather, changing prey base, ground-based disturbance) may
influence reproductive success and confound the ability to identify the ultimate factor in limiting productivity of a certain species, area, or region (Smith et al. 1988).

Based on identified recovery habitat for the Mariana fruit bat (USFWS 2010b), noise levels of 60 dB ADNL and greater would overlie 1,507 acres (610 ha) of recovery habitat in the vicinity of Alternative 4 (Table 5.4.8-5).

Given the ongoing poaching of fruit bats on Guam, it is likely that those fruit bats that currently occur on Guam will avoid areas of live-fire training as they may have experienced a poaching event. While there is the potential for eventual habituation by fruit bats to LFTRC live-fire activities, fruit bats are expected to initially avoid areas of live-fire training activities. Therefore, fruit bats may temporarily avoid approximately 1,507 acres (610 ha) of recovery habitat due to proposed live-fire range operations. However, proposed live-fire operations at the LFTRC are not continuous and would occur between 7:00 a.m. and 7:00 p.m. for 39 weeks per year, and night operations (estimated to occur 2 nights per week over 39 weeks per year) would occur between 7:00 p.m. and 10:00 p.m. or 6:00 a.m. and 7:00 a.m. In addition, live-fire operations would not physically impact recovery habitat. This temporary avoidance of recovery habitat on Guam would not preclude the recovery or survival of the fruit bat, and it would not substantially reduce the total number of fruit bats that the island can support.

With implementation of BMPs (see previous discussion of construction impacts under Vegetation), including ongoing implementation of standard DON and commercial biosecurity protocols (e.g., Port of Guam, A.B. Won Pat International Airport) regarding detection and management of non-native species, invasive species outreach and education, applicable elements of the SIP, and 1-year post-construction monitoring to evaluate effectiveness of HACCP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of Alternative 4 is considered unlikely. Therefore, there would be less than significant impacts to the Mariana fruit bat with implementation of proposed operational activities associated with Alternative 4.

MARINA CROW, GUAM RAIL, AND GUAM MICRONESIAN KINGFISHER. These species are extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of these species is reasonably certain to occur and the species are likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of these species, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the crow, rail, and kingfisher are successfully re-introduced and then have the potential to be exposed to operational activities under Alternative 4, there would be no impact to these species. If the species are reintroduced and exposed to LFTRC operational activities under Alternative 4, they may be disturbed.

MARINA SWIFTLET. Based on surveys conducted for this SEIS, swiftlets were observed within the vicinity of the proposed ranges or within the modeled noise contours associated with the proposed ranges under Alternative 4 (see Figure 5.4.8-2b). Swiftlets would continue to forage within the extensive foraging habitat to the north, west, and east of the proposed range areas, and areas in the vicinity of the nest/roost caves on NAVMAG and the drainages of the Mahlac, Maagas, and Talofofo rivers (see Figures
5.2.8-1 and 5.2.8-3). The proposed range operations would not impact regional insect populations that are the prey base for the swiftlet. In addition, swiftlets are generally more actively foraging in the early morning and late evenings before and after proposed range operations. As swiftlets do not have a history of being hunted, they would not have the same aversion to gunfire that Mariana fruit bats have, and therefore may not avoid areas of live-fire range operations. Proposed range operations and associated noise would not impact the swiftlet nesting/roosting caves approximately 1 mile (1.6 km) to the east of the proposed range in the northern portion of the Alternative 4 action area, and the nest caves would not be within the modeled noise contours associated with the proposed ranges. Therefore, given the extensive remaining foraging habitat within the surrounding areas that would still be available for foraging, and that swiftlets would still forage in the mornings and evenings before and after range operations, there would be less than significant impacts to the Mariana swiftlet due to proposed range operations under Alternative 4.

MARIANA COMMON MOORHEN. The modeled 55 dB ADNL noise contour overlies a pond to the east of the proposed range in the northern portion of the Alternative 4 action area (see Figure 5.4.8-2a). However, the low modeled noise level that may occur within the vicinity of the pond (i.e., 55 dB ADNL is approximately equal to ambient noise levels; see Section 3.4, Noise), there would be less than significant impacts to Mariana common moorhens with implementation of the proposed range operations under Alternative 4.

For the southern ranges under Alternative 4, the modeled 55 dB ADNL noise contour overlies the southern portion of Fena Valley Reservoir. However, moorhens primarily use the northern portion of the reservoir, near the spillway, for nesting, feeding and resting (Brooke and Grimm 2008; Brindock 2012). Given the low modeled noise level that may occur within the southern portion of the reservoir (i.e., 55 dB ADNL is approximately equal to ambient noise levels; see Section 3.4, Noise), and that moorhens predominantly use the northern portion of the reservoir that would be outside the 55-dB contour, there would be less than significant impacts to Mariana common moorhens with implementation of the proposed range operations under Alternative 4.

MARIANA EIGHT-SPOT BUTTERFLY. Some species of tropical butterflies have well-developed ears on their wings and can detect sounds at the same frequencies that humans can hear. It is hypothesized that the butterflies are listening to the flight sounds or foraging calls of predatory birds (Lane et al. 2008; Yack 2012). Given the low numbers of forest birds currently on Guam due to the brown treesnake, masking of the flight sounds or foraging calls of predatory birds due to noise from proposed construction activities would not make eight-spot butterflies more susceptible to predation.

Fire potential would increase due to proposed live-fire range operations. Fire can result in direct effects to vegetation by increasing erosion, allowing for the establishment of non-native species, and altering wildlife habitat by reducing food resources, breeding habitat, and shelter. Native plants and their habitats on Guam are adapted to a humid, tropical climate and are not adapted to a fire driven ecosystem (USFWS 2008a).

As a BMP and in accordance with range safety protocols, a Range Fire Management Plan would be prepared, based on the DON’s Wildland Fire Management Plan (Nelson 2008) (see Section 2.8). It would include protocols for monitoring fire conditions and adjusting training as needed (e.g., certain types of training may be disallowed under certain fire conditions), and location and management of firebreaks, fire-fighting roads, and a fire fighting water system. Units undergoing training would be briefed on requirements suitable to the conditions of the day and protocols should a fire occur (e.g., specifying how the range would shut down and how fire suppression action would be taken). With implementation of the
Range Fire Management Plan, which establishes management and fire suppression and emergency response procedures, potential impacts from range-related wildfires would be less than significant. The USFWS concluded in their BO for the 2010 Final EIS that they anticipated that no additional vegetation would be lost due to wildfires igniting as a result of proposed training operations (USFWS 2010a). Therefore, as operation of the range would not remove additional vegetation (e.g., host plants), there would be less than significant impacts to the Mariana eight-spot butterfly with implementation of proposed range operations under Alternative 4.

**Serianthes**. *Serianthes* does not occur within the Alternative 4 action area. Although fire potential could increase due to proposed live-fire range operations, with implementation of the proposed Range Fire Management Plan and procedures (see Vegetation above, and Section 2.8), potential impacts from range-related wildfires on *Serianthes* would be less than significant. Therefore, there would be less than significant impacts to *Serianthes* or recovery habitat due to proposed range operations under Alternative 4.

**Tabernaemontana rotensis** and **Cycas micronesica**. Although fire potential could increase due to proposed live-fire range operations, with implementation of the proposed Range Fire Management Plan and procedures (see Vegetation above, and Section 2.8), potential impacts from range-related wildfires on *T. rotensis* and *C. micronesica* would be less than significant. There would be no other impacts to *T. rotensis* and *C. micronesica* with implementation of the proposed range operations associated with Alternative 4.

**Special-Status Species: Guam-Listed and SOGCN**

**Pacific Slender-toed Gecko**. Although fire potential could increase due to proposed live-fire range operations, with implementation of the proposed Range Fire Management Plan and procedures (see Vegetation above, and Section 2.6), potential impacts from range-related wildfires on the Pacific slender-toed gecko would be less than significant. There would be no other impacts to the Pacific slender-toed gecko with implementation of the proposed range operations associated with Alternative 4.

**Merrilliodendron megacarpum**. Although fire potential could increase due to proposed live-fire range operations, with implementation of the proposed Range Fire Management Plan and procedures (see Vegetation above, and Section 2.8), potential impacts from range-related wildfires on *M. megacarpum* would be less than significant. There would be no other impacts to *M. megacarpum* with implementation of the proposed range operations associated with Alternative 4.

5.4.9 **Marine Biological Resources**

5.4.9.1 **Affected Environment**

As there are no in-water construction, dredging, or training activities and/or land-based construction activities under the proposed NAVMAG (L-Shaped) alternative that would affect the marine environment, the affected environment for marine biological resources under this alternative would remain unchanged.

5.4.9.2 **Environmental Consequences**

There are no in-water construction, dredging, or training activities and/or land-based construction activities proposed under the NAVMAG (L-Shaped) alternative that would directly affect the marine environment. Therefore, no direct or indirect impacts are expected.
Scoping comments noted concern regarding the possibility that contamination could migrate from the ranges through stormwater runoff. However, as discussed in Section 5.4.2, Water Resources, there would be no impacts to nearshore waters through implementation of surface water protection measures (i.e., compliance with Construction General Permit requirements and implementation of BMPs during construction and implementation of LID features in accordance with the DoD UFC LID [UFC 3-210-10] and Section 438 of the EISA, range maintenance BMPs, and pollution prevention plans during operations).

5.4.10 Cultural Resources

5.4.10.1 Affected Environment

The following discussion summarizes previous cultural resources studies, known historic properties, and other cultural resources within the PDIA and PIIA associated with Alternative 4. The Alternative 4 area, also known as NAVMAG (L-Shaped), is situated on the south-central portion of Guam and includes land within the NAVMAG and lands to the west and to the southeast of the NAVMAG. As early as December 1944, miles of roads and magazines were constructed at the NAVMAG and the area was commissioned on February 22, 1945 (Mason Architects and Weitze Research 2009). During a limited expansion in the Korean conflict of the early 1950s, most of the present main administration buildings and many of the magazines in what was known as the Naval Magazine or NAVMAG were designed and built as part of the permanent base development program for Guam.

The affected environment for cultural resources associated with Alternative 4 is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 12: Cultural Resources, Section 12.1.5.1: Naval Munitions Site, pages 12-33 to 12-37). This description of the affected environment is updated here with new information from recent archaeological and architectural investigations conducted for this SEIS and other projects. To determine whether site information is from previous investigations (such as the 2010 Final EIS or other cultural resource studies) or prepared during in-fill studies conducted for this SEIS, refer to dates in the reference column in each table for the archaeological sites. Certain information about built properties (such as date and function) was derived from INFADS.

Portions of the Alternative 4 PDIA and PIIA were surveyed for the presence of cultural resources for the original proposed action (2010 Final EIS). Those and other previous investigations in the area included archaeological surveys (Tuggle 1993; Hunter-Anderson 1994; Craib and Nees 1998; Henry et al. 1999; Allen et al. 2002; Hunter-Anderson and Moore 2002; Dixon et al. 2004; and Welch 2010), architectural inventories (Mason Architects and Weitze Research 2010; Welch 2010), and TCP studies (Griffin et al. 2010). Additional investigations conducted for this SEIS included intensive cultural resource inventories conducted for PDIA and reconnaissance inventories in PIIA for this SEIS (Dixon et al. 2015a, 2015b). Note that due to changes in the alternative as a result of the SEIS planning process, 71.8 acres (29 ha) in the PDIA and 182.53 acres (73.87 ha) in the PIIA were added for Alternative 4 after the surveys were conducted. These 254.3 acres (102.87 ha) were examined through historic materials, aerials, and a comparison with adjacent areas to assess impacts to cultural resources. Collectively, these investigations provide the comprehensive inventory of cultural resources for Alternative 4.

As described in Section 5.1.10.1, the HG Range would be located at Andersen South under all of the LFTRC alternatives. This area was previously surveyed at an intensive level (Welch 2010; Dixon et al. 2011a).
During October through December 2014, the DON consulted with the parties to the 2011 PA and the public on the Draft TRRA. Consistent with Stipulation V.C of the 2011 PA, the TRRA provided planning level information on potential direct and indirect effects to historic properties within areas that may be selected in the Navy’s ROD for the live-fire training range complex. The Draft TRRA included information on the locations, orientations, and designs of each proposed LFTRC location. In addition to receipt of written comments, DON cultural resources professionals conducted three consultation sessions with the parties to the PA to discuss the analysis. The DON will take all comments into account in preparing the Final TRRA, which is planned for publication shortly after this Final SEIS. Comments and considerations developed during the Draft TRRA consultation process have been incorporated in this Final SEIS and informed the Draft RMP, as required by Stipulation V.C.4 of the 2011 PA.

Cultural Resources in the Alternative 4 PDIA

Alternative 4 would involve the construction of individual ranges, support buildings, munitions magazine relocation area, and access roads (see Figure 2.5-5). This construction area comprises the PDIA. Table 5.4.10-1 lists 13 known archaeological sites located within the Alternative 4 PDIA within the NAVMAG. Eleven sites, including sites with latte sets, rockshelters, WWII military sites, and artifact scatters, are eligible for listing in the NRHP. Two sites, consisting of a WWII-era American military concrete slab and a small Latte Period artifact scatter, are not considered eligible for listing in the NRHP. No historic properties have been identified in the PDIA of the proposed HG Range at Andersen South.

No TCPs have been identified in the PDIA for Alternative 4.

Cultural Resources in the Alternative 4 PIIA

The PIIA comprises SDZs for the LFTRC and HG ranges and associated areas potentially affected by increases in noise. It includes no locations of potential direct impact due to construction. Table 5.4.10-3 summarizes the 248 known archaeological sites located within the Alternative 4 PIIA. There are 219 NRHP-eligible sites, including artifact scatters, latte sites, rockshelters, and historic military features. Twenty-seven sites have not been evaluated for listing in the NRHP and two sites are considered not eligible for listing in the NRHP. Should this alternative be selected, final assessments would be determined consistent with the procedures outlined in the 2011 PA.

Note: ** Revised to match Guam GHPI forms dated May 28, 2014.
   ^ Eligibility of this site has not been fully determined. However, for the purpose of this analysis, it is assumed eligible.
There are 56 architectural properties, constructed between 1944 and 2007, located within the PIIA for Alternative 4 (Table 5.4.10-4). These buildings and structures are primarily associated with WWII and Cold War-era ammunition storage and support facilities. Forty-one of the structures are ammunition storage facilities covered under the Program Comment for World War II and Cold War Era Ammunition Storage Facilities (ACHP 2006; see Chapter 3.10.3 for more information on the Program Comment). Eleven buildings and structures greater than 50 years in age have not been evaluated. Four structures are less than 50 years old and do not meet the exceptional significance threshold required under NRHP Criteria Consideration G. Should this alternative be selected, final assessments would be determined consistent with the procedures outlined in the 2011 PA.

Six potential TCPs have been identified in the PIIA for this alternative. They include Bona Springs, Alifan Peak, Almagosa Springs, Dobo Springs, Almagosa Mountain, and a high density area of *latte* sites (Griffin et al. 2010).
5.4.10.2 Environmental Consequences

Construction

Construction activities of Alternative 4 have the potential to affect historic properties and impact culturally important natural resources. Final determinations of effect would follow the procedures outlined in the 2011 PA. Following is a discussion of potential direct and indirect effects to historic properties and impacts to culturally important natural resources.

Construction of the ranges, support facilities, relocated magazine, and utilities would occur in NAVMAG and east of NAVMAG (see Figure 2.5-5). Given the substantial development anticipated in the PDIA, it is assumed for purposes of this analysis that 100% of the area would be disturbed. Nevertheless, design alternatives to avoid and minimize adverse effects would be considered, consistent with procedures in the 2011 PA. No construction would occur in the PIIA. Excavation and soil removal associated with the construction of Alternative 4 could adversely directly affect 11 known historic properties, including Pre-Contact artifact scatters, sites containing latte components, and WWII military sites (see Table 5.4.10-1). Seven of the historic properties are located within both the PDIA and the PIIA. Direct impacts to these sites would only occur to the portion within the PDIA. Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the 71.8 acres (29 ha) of unsurveyed areas within the PDIA. If this alternative were selected, final assessments would be determined consistent with the procedures in the 2011 PA.

Construction associated with Alternative 4 may also require the demolition of architectural properties. All of the buildings and structures are covered under the Program Comment for World War II and Cold War Era (1939-1974) Ammunition Storage Facilities (ACHP 2006), which resolves NHPA Section 106 requirements for their demolition.

Construction activities associated with Alternative 4 have the potential to directly impact culturally important natural resources. The project would require the removal of limestone forest and savanna vegetation where culturally important natural resources may be located. The 2011 PA contains measures for coordinating with the SHPO and concurring parties to contact traditional natural healers, herbal practitioners and traditional artisans regarding identification and disposition of these important resources prior to construction (see 2010 Final EIS, Volume 2: page 2-10; Volume 9: Appendix G, Chapter 4).

No historic properties or culturally important natural resources are anticipated in conjunction with utility upgrades that would be associated with Alternative 4 The modification or replacement of existing overhead electrical utilities under Alternative 4 would not affect any known cultural resources. There are no historic properties located in the PDIA or PIIA for the proposed HG Range at Andersen South. Therefore, no adverse effects to historic properties are anticipated due to construction of the HG Range.

Operation

Operations associated with Alternative 4 could cause indirect adverse effects to historic properties as discussed below. Final determinations of effect would follow the procedures in the 2011 PA. Following is a discussion of potential adverse effects of operations associated with Alternative 4.

The potential for direct effects within the SDZ would be limited to the risk of strikes from stray rounds during Alternative 4 operations. The risk of such effects occurring is extremely low. The range would be designed to contain live fire inside the range itself to minimize the probability of rounds landing in the SDZ. Additionally, if a stray round were to escape the range, the chance of it hitting a historic property is
remote, given the size of the SDZ and dispersal of historic properties. For these reasons, the potential for direct adverse effects as a result of range operations is de minimis.

Indirect adverse effects to NRHP-eligible archaeological sites from the operation of Alternative 4 could result from changes affecting site integrity. For many types of archaeological sites (e.g., ceramic scatters, rock alignments), auditory impacts associated with live-fire operations would not affect characteristics that qualify them for the NRHP. An increase in noise associated with live-fire operations may adversely affect historic properties for which solitude, quiet, or contemplation contribute to or define their significance, such as TCPs. Under Alternative 4, small arms live-fire noise would be audible near 40 NRHP-eligible sites, 20 unevaluated sites, one not eligible site and two potential TCPs (Bona Springs and Alifan peak) that are located within the expanded noise contours (Table 5.4.10-5). Average noise levels during range operations are projected to increase from current levels of approximately 45 dB to between 65 dB and 85 dB ADNL (see Section 5.4.4, Noise). Thirty-two of the sites are Pre-Contact artifact scatters or features, rockshelters/caves, and historic military features, while 29 sites contain latte components. Auditory impacts associated with range operations would not adversely affect the integrity of the NRHP-eligible artifact scatters, historic military features, or other historic remains. Changes to the setting of the 29 sites (24 eligible for listing in the NRHP and 5 unevaluated) with latte components could be adverse. There may also be an effect to two potential TCPs. Final determinations of effect would follow the procedures in the 2011 PA.

</table>

Notes: ^ Eligibility of this site has not been fully determined. However, for the purpose of this analysis, it is assumed eligible.
Similar to historic military sites, noise associated with range operations is not likely to adversely affect the integrity of ammunition storage support facilities. Therefore, no indirect effects are anticipated to buildings and structures from changes in noise levels. No indirect adverse effects from visual intrusions associated with Alternative 3 are anticipated, as the ranges are within an existing military operations area and the action would not involve a change in visual setting.

Access to all sites within the PIIA would be restricted during range operations; however, most of these sites are located within areas that currently have limited access due to operations at NAVMAG or their remote locations. Members of the public have requested to visit Almagosa Springs and other areas of NAVMAG in the past and there is a process to access certain areas. Therefore, indirect impacts could result from additional restriction on access to four potential TCPs (Almagosa Springs, Dobo Springs, Almagosa Mountain, and a high density area of latte sites). The 2011 PA requires development of plans for regular public access to historic properties for DoD-controlled lands on Guam, subject to considerations including but not limited to public interest, public safety concerns and protocols, installation security, and emergency situations.

Summary of Impacts and Potential Mitigation Measures

Implementation of Alternative 4 could cause direct, adverse effects to 11 known NRHP-eligible archaeological sites. Potential indirect adverse effects could occur to 24 NRHP-eligible archaeological sites with latte components. Undetermined effects could occur to five unevaled archaeological sites with latte components and two potential TCPs. Four potential TCPs could also be indirectly impacted by reduced accessibility. In addition, culturally important natural resources could be directly impacted due to removal of limestone forest and savanna vegetation. If this alternative were selected, final assessments would be determined consistent with the procedures identified in the 2011 PA.

Adverse effects that could occur from construction and operation under this alternative would be less than under Alternative 5 (the greatest effects from construction would occur under Alternative 5, and the greatest effects from operation would occur under Alternative 5). Refer to Section 5.7, Table 5.7-1 for a comparison of cultural resources impacts and potential mitigation measures for each LFTRC alternative.

The 2011 PA, as discussed in Section 3.1.2, establishes a program alternative for complying with NHPA Section 106 requirements. Broadly, the 2011 PA includes processes to share information, consider views of the public, and develop mitigation measures when historic properties are adversely affected. The 2011 PA provides measures for mitigating adverse effects to NRHP-eligible or listed archaeological sites, consulting on new projects and initiating additional identification efforts, and resolving impacts due to loss of access to areas of cultural importance or culturally important natural resources.

More specifically, the 2011 PA established a process for the review and analysis of potential effects to historic properties and other cultural resources for all alternative LFTRC locations. During October through December 2014, the DON consulted with the parties to the PA and the public on the TRRA, which provided information about cultural resources potentially affected by the LFTRC alternatives carried forward in the SEIS, consistent with PA Stipulation V.C. The TRRA provides information on potential adverse effects resulting from the construction and operation of the LFTRC alternative to support consultation with the PA parties and the public. The DON will take all comments into account before reaching a final decision. For any alternative selected in the ROD, the 2011 PA stipulates that a RMP will be prepared to address effects from the construction and operation of the ranges. The RMP, developed in consultation with the consulting parties, will stipulate measures to avoid, minimize, and mitigate adverse effects to historic properties.
To the degree possible, impacts to historic properties and resources of cultural importance would be avoided or minimized during the planning process. Consultation under the 2011 PA would address potential adverse effects and alternatives to avoid adverse effects. Refer to Section 3.10 for more information on definitions and procedures. If avoidance is not possible, Table 5.4.10-6 presents potential mitigation measures to resolve adverse effects to historic properties and reduce impacts to cultural resources resulting from the implementation of Alternative 4. With the implementation of these measures and processes as outlined in the 2011 PA, it is expected that direct and indirect, short-and long-term impacts would be reduced to a level below significance.

5.4.11 Visual Resources

5.4.11.1 Affected Environment

The 2010 Final EIS describes the proposed activities at NAVMAG (Volume 2, Chapter 2: Proposed Action and Alternatives, Section 2.3.1: Requirements, page 2-49). Although Alternative 4 differs from the 2010 Final EIS activities at NAVMAG, the potentially affected visual environment and the visual resources themselves would remain the same. A list and description of visual resources at the NAVMAG is provided in the 2010 Final EIS (Volume 2, Chapter 13: Visual Resources, Section 13.1.4.1: Naval Munitions Site, pages 13-54 to 13-57). See Section 4.3.11 for a summary of the visual resources at NAVMAG.

5.4.11.2 Environmental Consequences

Similar to Alternative 3, this alternative would involve construction of a live-fire range and a range maintenance building 3 miles (5 km) north of Mount Lamnam and 4 miles (6 km) north of the publicly accessible Jumullong Manglo Overlook. The Alternative 4 facilities may be visible from the public areas as well as from the trails leading up to them. Unlike Alternative 3, the remaining live-fire range facilities
would be located east of NAVMAG, on land that would be acquired. These facilities would not be visible from the aforementioned publicly accessible areas.

Construction

During construction, activities and equipment would temporarily cause view obstructions where recognized views currently exist. The visual impacts during the construction phase would be temporary and less than significant.

Operation

The Alternative 4 facilities may be visible from Jumullong Manglo Overlook, as well as from the trails leading up to the Overlook near the top of Mount Lamlam, a National Natural Landmark. The elevations of both Mount Lamlam (the highest point on Guam) and Jumullong Manglo Overlook could result in the ability to see portions of the 1 mile (2 km) of new roadways, areas of removed vegetation and cut/fill features, and earthen berms, as well as some of the proposed structures such as some of the 66 relocated ordnance magazines.

The impact on visual resources would be significant. However, because fewer facilities are proposed at the northern end of NAVMAG, this alternative’s impact on visual resources, although still significant, would be less than that of Alternative 3. Potential mitigation measures to reduce this impact to less than significant are the following:

- To maintain the existing visual appearance, land clearing and grading should be minimized to the extent possible on lands proposed for range uses.
- Minimize impact by using native flora to create a natural-appearing “screen” around the cleared range areas, outside of the firebreaks/perimeter roads.

Alternative 4 would have a greater impact to visual resources than Alternatives 1, 2, and 5 because of the potential long-term ability to see the new structures from public viewing areas. Alternative 4 would have a lesser impact than Alternative 3, because fewer of the proposed roadway and ordnance magazines would be visible.

5.4.12 Ground Transportation

5.4.12.1 Affected Environment

The affected environment for ground transportation resources associated with the NAVMAG (L-Shaped) LFTRC alternative includes transportation facilities internal to the site (range roadways and intersections). This section discusses existing conditions and assesses how Alternative 4 would potentially affect transportation conditions for roadways and intersections internal to the site. Impacts to off-base (external) roadways and intersections are summarized in Section 6.1 of this SEIS.

5.4.12.2 Environmental Consequences

Construction

Potential construction impacts to ground transportation under Alternative 4 would be the same as those described in Section 4.2.12.2 for Alternative A. Potential direct and indirect impacts to ground transportation resources from construction would be minimized with implementation of appropriate work zone traffic management strategies and BMPs. Therefore, there would be less than significant short-term impacts to on-base (internal) roadways.
Operation

Proposed access to Alternative 4 would be from the existing NVMAG Main Gate located on Route 5. The proposed Alternative 4 would have ranges and facilities in two locations. This would reduce the efficiency in both range maintenance and management, and would result in additional travel between the two areas. The MPMG and Range Maintenance Building would be in the same location as Alternative 3. All other ranges would be located on non-federal property east of the NVMAG site. Existing roadways would be used wherever possible. However, this alternative requires the construction of an access road to allow all-weather operations. A total of 3.0 miles (5.0 km) of internal roadways would be required to support LFTRC operations.

Traffic generated by Marine Corps training activity is discussed in Section 5.2.12.2 and summarized in Tables 5.1.12-1 and 5.1.12-2. This traffic represents the maximum potential adverse effect for traffic.

Potential operational impacts for Alternative 4 would be the same as those described in Section 5.1.12.2 for Alternative 1; there would be no direct, long-term significant impacts to internal (range) roadway segments or intersections.

5.4.13 Marine Transportation

5.4.13.1 Affected Environment

The NVMAG (L-Shaped) LFTRC alternative and SDZ do not extend over open waters used by vessels. Thus, there is no marine transportation in the proposed area.

5.4.13.2 Environmental Consequences

Implementation of Alternative 4 would not impact open waters used by vessels. Therefore, it is expected that there would be no impact to marine transportation due to the construction and operation of Alternative 4.

5.4.14 Utilities

5.4.14.1 Affected Environment

Existing utilities in the vicinity of the proposed HG Range are the same as discussed in Section 5.1.14.1 for Alternative 1.

Alternative 4 is essentially a combination of Alternatives 2 and 3, with the LFTRC ranges split between the existing NVMAG area and private lands to the east of the current NVMAG area.

Electrical Power

The electrical utility that would be near the proposed NVMAG (L-Shaped) LFTRC Alternative 4 site consists of an existing local GPA power distribution system buried underground in the existing Dandan Road (at the beginning of the proposed new access road), and the DON power distribution system at the NVMAG complex. The GPA system includes buried power lines and manholes along Dandan Road. This distribution system primarily serves the Dandan communication installation and the Layon Landfill. The DoD distribution system includes electrical lines and transformers serving the existing NVMAG area, including the water treatment plant and Fena Reservoir.

Potable Water

The potable water system near the proposed Alternative 4 site includes a local GWA water distribution system buried underground in the existing Dandan Road as described in Section 5.2.14 (Alternative 2).
and a local DoD water distribution system on the existing NAVMAG property as described in Section 5.3.14 (Alternative 3).

**Wastewater**

The wastewater utility near Alternative 4 consists of an existing GWA underground wastewater collection system in the existing Dandan Road (at the beginning of the proposed new access road) and DoD wastewater collection systems buried underground in the existing NAVMAG area.

**Solid Waste**

There are no solid waste facilities near Alternative 4. The GovGuam landfill is located on Dandan Road, past the beginning of the proposed new LFTRC access road. Dandan Road is the primary haul route for trash trucks going to this landfill. Solid waste from the existing NAVMAG facilities is collected, processed, and disposed by contractors for JRM.

**Information Technology and Communications**

There is existing DoD IT/COMM infrastructure near Alternative 4 at the existing NAVMAG property. There are buried commercial IT/COMM lines along Dandan Road, but none near the proposed LFTRC.

**Environmental Consequences**

5.4.14.2 Environmental Consequences

Potential impacts to existing utilities from operation of the HG Range would be the same as discussed in Section 5.1.14.2 for Alternative 1.

**Electrical Power**

The proposed electrical system improvements for Alternative 4, as described in Sections 2.5.4.4 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The electrical power requirements of the LFTRC facilities would be small (less than 50 kW) and thus have minimal long-term impact on the current system or current power customers. During construction, short-term power outages could occur while new power lines are connected to existing power lines, but they are expected to be only about 2 hours.

The short- and long-term, direct impact of LFTRC Alternative 4 on the electrical utility would be less than significant during both construction and operation.

**Potable Water**

The proposed water system improvements for Alternative 4 as described in Sections 2.5.4.4 and 2.5.4.6 (for HG Range) have been developed to meet the requirements for the proposed action. The KD Rifle/KD Pistol Range Administrative Building is the only facility on the east side of Alternative 4 requiring potable water service. The demand of this facility would be small, estimated at a portion of the total LFTRC average daily demand of 26,520 gallons per day (100,389 liters per day). Therefore, less than significant long-term, direct impact would occur to the current GWA system. During construction, short-term, minor water service outages could occur as new water lines are connected to existing water lines. With careful planning, these potential outages would be minimized.

For Alternative 4, the new water service to the LFTRC facilities on NAVMAG property would connect to the proposed Range Maintenance Building and new fire hydrant. The long-term demand of these LFTRC connections would also be small, estimated at a portion of the total LFTRC average daily demand of 26,520 gallons per day (100,389 liter per day). Therefore, less than significant long-term, direct impact would occur to the current DoD water system. During construction, short-term, minor water service
outages could occur as new water lines are connected to existing water lines. With careful planning, these potential outages would be minimized.

The short- and long-term, direct impact of LFTRC Alternative 4 to the potable water utilities (both DoD and GWA) would be less than significant, during both construction and in operation.

**Wastewater**

The proposed wastewater collection system improvements for Alternative 4, as described in Sections 2.5.4.4 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The only LFTRC facilities that would generate wastewater would be the Range Maintenance Building and the KD Rifle/KD Pistol Range Administrative Building that would have an estimated wastewater flow less than 0.01 MGd (0.038 MLd). The short- and long-term, direct impacts to the wastewater utility would be the same as for Alternative 3, as discussed in Section 5.3.14.2.

The short- and long-term impact of LFTRC Alternative 4 to the wastewater utility would be less than significant, during both construction and operation.

**Solid Waste**

The proposed solid waste infrastructure improvements for Alternative 4, as described in Sections 2.5.4.4 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The short- and long-term, direct impacts to the solid waste utility from Alternative 4 would be the same as for Alternative 3, as discussed in Section 5.3.14.

The short- and long-term, direct impact of LFTRC Alternative 4 on the solid waste utility would be less than significant, during both construction and operation.

**Information Technology and Communications**

The proposed IT/COMM infrastructure improvements for Alternative 4 as described in Section 2.6 have been developed to meet the requirements for the proposed action. LFTRC Alternative 4 would require new conduit duct banks consisting of six 4-inch (10-cm) conduits to interconnect the LFTRC range facilities including the HG Range. There would also be inter-base connectivity required for DoD IT/COMM, as discussed in Section 2.6. Some of these inter-base connections in the southern part of Guam would require new rights of way. Installation of these IT/COMM lines could cause short-term minimal service disruptions to current IT/COMM users. With careful planning, these potential disruptions would be minimized.

The short- and long-term, direct impact to the IT/COMM infrastructure would be less than significant, during both construction and operation.

**5.4.15 Socioeconomics and General Services**

Most issues and impacts associated with socioeconomics and general services encompass the entire proposed action (i.e., cantonment/family housing and LFTRC development, increased population), and do not vary with site alternatives. Accordingly, the impact discussion in Section 4.1.15 of this SEIS applies for all of the LFTRC alternatives and is incorporated here by reference. Land acquisition, however, is unique to the LFTRC alternatives, and the amount of land to be acquired varies by alternative. Therefore, this section focuses exclusively on the socioeconomic and sociocultural issues and impacts associated with the acquisition of land under Alternative 4 (with the exception of the HG Range, which would not require land acquisition).
5.4.15.1 Affected Environment

Table 5.4.15-1 displays baseline data for land that would be acquired for the NAVMAG (L-Shaped) LFTRC alternative. A total of 974 acres (394 ha) of land would be acquired by the federal government. Most of the land (695 acres [281 ha]) is privately owned, including at least nine of the 30 lots that would potentially be acquired. GovGuam owns 205 acres (83 ha) spread over three lots. Eighteen lots that would be acquired have unknown ownership.

Table 5.4.15-2 shows existing land use in the NAVMAG (L-Shaped) acquisition area. Land use on the NAVMAG L-Shaped parcel consists of 792 acres (321 ha) of undeveloped land and 182 acres (74 ha) of conservation land (a portion of the Bolanos Conservation Area), where development is not allowed. The GBSP land classification for the entire acquisition area is Agriculture. However, as described in Section 5.4.6, Land Use, no current agricultural use was identified. None of the acreage currently has a productive economic use.

With regard to the affected fiscal environment of Guam, as stated in Section 5.1.15, GovGuam collected a total of $20.1 million in property tax revenues. These revenues accrue to the GovGuam general fund.

5.4.15.2 Environmental Consequences

The DON is required to comply with federal land acquisition laws and regulations, which include the requirement to offer just compensation to the owner, to provide relocation assistance services and benefits to eligible displaced persons, to treat all owners in a fair and consistent manner, and to attempt first, in all instances, acquisition through negotiated purchase. Specific policies and procedures, including the Uniform Act, are described in detail in Section 5.1.15.2.

While the government is authorized to acquire property through its powers of eminent domain (condemnation), it has been the consistent policy of the DON to acquire real estate through negotiation with owners. Even with a negotiated sale or lease however, “friendly” condemnation may be necessary to
clear problems with title. The DON would comply with all applicable laws and regulations, including the Uniform Act.

In general, assuming voluntary sale or lease of property and conformance with land acquisition laws and regulations, land acquisition impacts from both a socioeconomic and sociocultural perspective would not be considered significant. Should condemnation be necessary as a last resort, while the landowner would be made economically whole by payment of fair market value, such an occurrence could represent an adverse sociocultural impact for that individual landowner. Such instances are expected to be extremely rare or nonexistent during implementation of this proposed action, and collectively would not represent a significant impact.

**Socioeconomic and Sociocultural Impacts**

Potential impacts associated with land acquisition could affect individual property owners, occupants, the surrounding community, and GovGuam. Economic impacts presented in this section are total impacts, they include impacts that would be generated by the proposed action both directly and indirectly. Individual owners and occupants might be impacted from an economic perspective or a sociocultural perspective. Economic impacts associated with land acquisition are those that are purely financial. Sociocultural impacts associated with land acquisition are less tangible and are based on conceptual frameworks such as social disarticulation and cultural marginalization (the deterioration of social structures, networks, or belief systems), and social and psychological marginalization, stress, and anxiety (a person’s loss of confidence in society and themselves, feelings of injustice, and reduced social status). See Appendix D, Section 5.2.2 for more detail.

**Individual Owner/Occupants**

With regard to economic impacts, if acquisition of privately-owned lots were to occur through negotiated purchase with the owners, there would be no adverse impact. As required under the Uniform Act, the purchase would take place at fair market value. Conversely, if the property was acquired through condemnation the federal government would still be required under the Uniform Act to reimburse the property owner at the fair market value. Therefore, the land acquisition would not cause an adverse economic impact to individual landowners.

With regard to sociocultural impacts, this alternative would require the acquisition of 30 separate lots, including three lots owned by GovGuam. Of the lots required, nine are known to be privately owned and 18 lots have unknown ownership, so up to 27 different private parties could be affected. It is anticipated that, in all cases, a negotiated sale or lease between the federal government and a willing seller would be arranged, and there would be no adverse sociocultural impact. In the unlikely event that the land is acquired through condemnation, it is possible that the individual landowner would potentially consider the forced sale or lease of property to be an adverse impact (despite being paid fair market value).

**Community**

With regard to economic impacts, the NAVMAG (L-Shaped) lands are either undeveloped in a natural state or represent conservation lands (see Table 5.4.15-2), and no current agricultural activities or other economically productive land uses were identified. Because the land that would be acquired does not currently have an economically productive use, and the fair market value would account for the highest and best use, there would be no adverse economic impact.

With regard to sociocultural impacts, the addition of an estimated 974 acres (394 ha) of federal land on Guam would be considered by some citizens to be an adverse impact due to the current extent of federal
land that is under DoD custody and control (25.9\% of all land on Guam, see Section 5.1.15), which would increase to 26.6\% with acquisition of the NAVMAG (L-Shaped) parcel. However, because of the DON’s commitment to the concept of “net negative,” by the end of the Marine Corps relocation there would be no net increase in federal land under the custody and control of the DoD.

Five recreational sites are located in the vicinity of the NAVMAG (L-Shaped) parcel (See Section 5.4.7 of this SEIS). Four of the five recreational sites are located on NAVMAG and are only open to installation personnel and their guests. The remaining recreational site, Talofofo Falls Park and Hiking Trail, is accessible to the public along the existing access road between Route 4 and the Dandan Communication Site and is not located within the land acquisition boundary. Although access to Talofofo Falls Park and Hiking Trail may be temporarily affected during construction activities along the access road, the proposed construction activities along the access road would be short-term in duration, and associated sociocultural impacts would be less than significant.

**Government of Guam**

The current 695 acres (281 ha) of land in the NAVMAG (L-Shaped) alternative that are privately owned are subject to GovGuam property tax. The average per acre value for these parcels is $206,911. The total tax base for private lands is estimated to be $143.8 million ($206,911 x 695 acres). On this property, land owners pay an estimated $122,232 in property taxes to GovGuam. Acquisition of this property by the federal government would represent a loss of 0.6\% of FY 2011 GovGuam property tax revenues, representing an adverse but less than significant impact.

GovGuam owns 205 acres (83 ha) of the land subject to acquisition under this alternative. At present, this land is not developed, leased or otherwise generating income for GovGuam. As such, either a sale or lease would generate a small beneficial economic effect (though less than significant in magnitude).

### 5.4.16 Hazardous Materials and Waste

The current DoD ROI on Guam for hazardous materials and waste in this section includes the DON property and GovGuam lands proposed for development of an LFTRC. The DON property includes northwestern portions of the NAVMAG site and an area to the northwest of Fena Valley Reservoir. GovGuam lands include undeveloped lands located to the east of the southern portion of the NAVMAG site.

#### 5.4.16.1 Affected Environment

**Hazardous Materials and Waste, Contaminated Sites, and Toxic Substances**

The affected environment or present conditions at NAVMAG and adjacent GovGuam lands proposed for live-fire training range development are depicted in Figure 5.4.16-1. The affected areas for Alternative 4 encompass the same areas as Alternative 2 and Alternative 3 and are described in Sections 5.2.16 and 5.3.16 of this SEIS.

#### 5.4.16.2 Environmental Consequences

**Hazardous Materials and Wastes**

The short-term and long-term environmental impacts associated with the development of an LFTRC under Alternative 4 would be similar to those described in Section 5.1.16.2 of this SEIS. However, because the training ranges and associated SDZs would be land based, there would be no direct impacts to open waters. As described in Section 5.1.16.2, direct and indirect impacts would be less than significant.
IRP Sites and MMRP Sites in the Vicinity of NAVMAG (L-Shaped) LFTRC Alternative 4

Figure 5.4.16-1

Source: NAVFAC Pacific 2013
Contaminated Sites and Toxic Substances

Construction and operation of Alternative 4 would occur in the same areas as Alternative 2 and Alternative 3. Therefore, impacts associated with this alternative would be similar to those described in Section 5.2.16.2 and Section 5.3.16.2 of this SEIS.

5.4.17 Public Health and Safety

5.4.17.1 Affected Environment

Operational Safety

Currently, no vehicle access exists to the southern portion of the area proposed as the NAVMAG (L-Shaped) LFTRC alternative. To protect the general public from intentional or accidental entry onto NAVMAG property, locked or manned gates are used where vehicle access is provided, and a series of warning signs cautioning unauthorized personnel not to enter the area are posted along the perimeter of the installation. Unauthorized personnel are not allowed on the installation at any time.

A small arms range and sniper range are present on the west-central portion of NAVMAG. In addition, an emergency demolition range is present in the central portion of NAVMAG, west of the Fena Valley Reservoir. Both of these ranges are within the SDZ footprint for Alternative 4. Activities at these ranges are conducted in accordance with SOPs to ensure the safety of range participants and the general public.

The munitions operations and storage area and the emergency demolition range on NAVMAG have associated ESQD arcs that restrict the construction of inhabited buildings and other non-munitions related activities, to minimize potential impacts on personnel and the general public from an explosive mishap. Explosives handling and storage is the primary function within the munitions storage area. Detonation of UXO in emergency situations is the primary function of the emergency demolition range.

Environmental Health Effects

Noise

Aviation training is limited to four helicopter landing zones at NAVMAG. Landing Zones 1 and 2 are within proposed SDZs associated with Alternative 4 development. Landing Zone 1 is used in airborne raid-type training associated with an adjacent breacher house. The overflight of helicopters produces noise. However, this training is infrequent and occurs at locations within the installation that is a distance away from populated areas, resulting in no community noise effect. In addition, a small arms range and sniper range are internal to the installation and do not present a current noise management issue.

Land demolition activities take place at the NAVMAG demolition range in the central portion of the installation (approximately 4,100 feet [1,250 m] from the closest public boundary). Although individuals exposed to these noise events may be startled if they are unaware of the source of the noise, the brevity and relative infrequency of activities does not result in noise contours extending onto adjacent public lands. Details regarding current noise conditions at NAVMAG are provided in Section 5.4.4.1.

Water Quality

The Fena Valley Reservoir, which is the primary drinking water source for the southern portion of Guam, is within the NAVMAG boundary. Water quality from the Fena Valley Reservoir and regional springs is generally high, requiring minimum treatment and chlorination for domestic use. Threats to water quality include sedimentation from accelerated erosion, eutrophication because of persistent conditions of low dissolved oxygen, and fecal material contamination from animals (DON 2010a). Section 5.4.2.1 provides details regarding current quality of potable water sources.
Hazardous Substances

Management practices and contingency plans for the use, handling, storage, transportation, and disposition of hazardous substances associated with NAVMAG ensure that exposure to the environment and human contact is minimized.

The IRP focuses on cleaning up releases of hazardous substances that pose risks to the general public and/or the environment. The MMRP focuses on identifying and removing MEC. U.S. Naval Activities Site 35 (Tear Gas Burial Site) is situated in the vicinity of the proposed MPMG live-fire training area, but would not directly affect Alternative 4 development. Contaminants of concern at this site include polynuclear aromatic hydrocarbons. Land use controls are in place at this site. A small arms range and sniper range (MMRP Site UXO 3) are present on the west-central portion of NAVMAG. In addition, an emergency demolition range is present in the central portion of NAVMAG, west of the Fena Valley Reservoir. Activities at these ranges are conducted in accordance with SOPs to ensure the safety of both range participants and the general public. The hazardous materials and waste section of this SEIS (see Section 5.4.16) provides additional details about the status of IRP and MMRP sites.

Unexploded Ordnance

The presence of UXO within Alternative 4 is unknown. However, Guam was an active battlefield during WWII. As a result of the occupation by Japanese forces and the subsequent assault by Allied/American forces to retake the island, unexploded military munitions may still remain.

Traffic Incidents

No high crash frequency locations have been identified in the vicinity of Alternative 4.

5.4.17.2 Environmental Consequences

Potential impacts on public health and safety from implementation of Alternative 4 would be similar to those discussed under Alternative 2.

Operational Safety

Construction Safety

Potential impacts from construction safety would be similar to those discussed for Alternative 2. During construction activities, a health and safety program would be implemented by the construction contractors based on industry standards for accident and pollutant release prevention. Because a health and safety program would be implemented for construction activities, and the general public would be excluded from entering construction areas, potential short-term construction impacts on public health and safety would not result in any greater safety risk. Therefore, no direct or indirect impact on public health and safety related to construction activities is anticipated.

Operation/Range Safety

To protect the general public from intentional or accidental entry onto live-fire training ranges, a series of warning signs cautioning unauthorized personnel not to enter the area would be posted along the perimeter of the installation, as well as at the range area. Unauthorized personnel would not be allowed on the installation or range at any time.

SOPs require that before conducting training activities, the general public and non-participating personnel would be cleared from the area so that the only public health and safety issue would be if a training event exceeded the safety area boundaries. Risks to public health and safety would be reduced by confirming
that the training area is clear. The Range Safety Officer would ensure that hazardous areas are clear of personnel during training activities. After a live-fire event, the participating unit would ensure that weapons are safe and clear of live rounds.

Use of established training areas and compliance with appropriate range safety procedures would reduce the potential for interaction between the general public and personnel that are training. Specific and documented procedures would be in place to ensure the general public is not endangered by training activities. Therefore, Alternative 4 would result in no direct or indirect impact on public health and safety from operations and training activities.

**Explosive Safety**

Ordnance used at the LFTRC would be handled, stored, and transported in accordance with Marine Corps explosive safety directives (MCO P8020.10A, *Marine Corps Ammunition Management and Explosives Safety Policy Manual*), and munitions handling would be carried out by trained, qualified personnel. For the proposed LFTRC under Alternative 4, SDZs were defined for each of the ranges to identify the areas requiring control of unauthorized access to live-fire training operations. The SDZs established for Alternative 4 reflect a “worst case scenario” for weapons use to ensure the safety of on- and off-range personnel and civilians. The proposed layout of the SDZs is provided in Chapter 2. With implementation of appropriate range safety procedures, no direct or indirect impact on public health and safety is anticipated.

The munitions operations and storage area as well as the emergency demolition range on NAVMAG have associated ESQD arcs that restrict the construction of inhabited buildings and other non-munitions related activities, to minimize potential impacts on personnel and the general public from an explosive mishap. The ESQD arcs overlay Alternative 4 firing positions and the associated SDZs. Because the ESQD arcs overlay propose live-fire training firing positions and SDZs, a conflict between the current munitions storage and EOD range activities with the proposed live-fire training activities would occur. However, munitions magazine relocation is included in Alternative 4 to eliminate this conflict. An explosive safety review would be needed to ensure compatible development and use. In addition, SDZs for Alternative 4 activities encumber the existing breacher house, sniper range, EOD range, Landing Zones 1 and 2, and a portion of the non-firing maneuver area, resulting in a safety conflict between the use of these facilities/areas and the proposed live-fire training activities. Use of these facilities/areas would be prohibited when Alternative 4 supports live-fire training. The emergency destruction mission of the EOD range would take precedence over Alternative 4 activities. As part of Alternative 4 development, munitions magazines would be relocated to eliminate the conflict between proposed Alternative 4 live-fire training locations and existing ESQDs for current NAVMAG mission activities, and the conflict between SDZs and current NAVMAG facilities/mission areas. Therefore, no significant safety impacts (direct or indirect) are anticipated if incompatible munitions magazines are relocated.

**Environmental Health Effects**

**Noise**

Potential impacts on public health and safety from Alternative 4 noise would be similar to those discussed for Alternative 2. Increases in noise emissions associated with implementation of the short-term construction phase of this alternative with identified BMPs would be less than significant. Enforcement of OSHA guidelines for hearing protection for workers would be the responsibility of the construction contractor. Noise from Alternative 4 activities (i.e., weapons firing) would be heard on adjacent lands from the range. Some adjacent lands north and west of Alternative 4 include residential uses.
no people would be exposed to incompatible noise levels (see Section 5.4.4.2 of this SEIS). The sound generated from Alternative 4 activities would be intermittent (only when training activities occur) and short term. This potential noise effect would not result in loss of hearing to nearby residents. Based on the modeled noise for Alternative 4 activities (see Section 5.4.4 of this SEIS), the overall direct or indirect impacts associated with noise on public health and safety would be less than significant.

**Water Quality**

Potential impacts on public health and safety from water quality concerns would be similar to those discussed for Alternative 2. Water withdrawal would likely increase. However, sustainability practices would be implemented to reduce the amount of water needed (see Section 5.4.2.2 of this SEIS). The resulting total annual water withdrawal would be less than the sustainable yield, and monitoring of water chemistry would identify any emerging issues to ensure no harm to the water supply.

The Fena Valley Reservoir is within the NAVMAG boundary and is the primary drinking water source for the southern portion of Guam. The reservoir is located southeast of Alternative 4 and is outside established SDZs for live-fire training activities. The SDZs define the ground area needed to contain projectiles, fragments, debris, and components resulting from the firing, launching, and/or detonation of weapons. Because Alternative 4 activities would be contained within the designated SDZs, no direct or indirect impact on the Fena Valley Reservoir is anticipated.

Because measures would be taken to maintain a sustainable water supply and the Fena Valley Reservoir is outside the SDZs for the Alternative 4 activities, public health and safety impacts from long-term increased demand on potable water and potential water-related illnesses would be less than significant.

**Hazardous Substances**

Potential safety impacts from use of hazardous substances would be similar to those discussed for Alternative 2. Implementation of this alternative would result in an increase in the use, handling, storage, transportation, and disposition of hazardous substances. These activities would be conducted in accordance with applicable hazardous material and waste regulations, and established BMPs and SOPs to ensure the health and safety of workers and the general public is maintained. IRP and MMRP investigations and/or remediation activities, as necessary, would continue in an effort to clean up past releases of hazardous substances that pose a risk to the general public and the environment, and receive regulator concurrence that necessary actions have been completed to ensure the safety of the general public. Because hazardous substance management and IRP/MMRP investigative/cleanup activities would be conducted in accordance with applicable regulations and established BMPs and SOPs, no direct or indirect impact on public health and safety is anticipated.

With regard to exposure to airborne toxic dust related to live-fire training activities and range maintenance, lead is the primary contaminant of concern. Very small lead particles can become airborne if wind, foot traffic, or maintenance activities disturb lead-contaminated soil. Firing ranges would be designed and constructed so that participating personnel are not exposed to airborne contaminants above permissible limits. No residential population is located near Alternative 4 on NAVMAG and emissions migrating off range would likely be much lower than on-site. Analysis of firing range emissions presented in the 2010 Final EIS (Volume 2, Chapter 5: Air Quality, Section 5.2.7: Summary of Impacts, Table 5.2-8, page 5-36) indicated that operations emissions from firing range components would be well below significance criteria. Because range maintenance procedures ensure that participating personnel are not exposed to airborne contaminants above permissible limits and analysis of firing range emissions are
below significance criteria, a less than significant direct or indirect impact on public health and safety from firing range activities is anticipated.

**Unexploded Ordnance**

Potential impacts from UXO would be similar to those discussed for Alternative 2. Excavation for building foundations, roads, underground utilities, and other infrastructure could encounter unexploded military munitions in the form of UXO, DMM, and/or MPPEH. Exposure to MEC could result in death or injury to workers with the exception of public access provisions outlined through the 2011 PA process (see Section 4.4.10, Cultural Resources), the general public would be excluded from entering construction zones and training areas. To reduce the potential hazards related to the exposure to MEC, ESS documentation would be prepared to outline specific measures that would be implemented to ensure the safety of workers and the general public. BMPs that would be implemented would include having qualified UXO personnel perform surveys to identify and remove potential MEC items before beginning ground-disturbing activities. Additional safety precautions would include having UXO personnel supervision during earth-moving activities and providing MEC awareness training to construction personnel involved in grading and excavations before, and during, ground-disturbing activities. In addition, the DON provides MEC awareness training to GovGuam and other public representatives, and allows access to project sites to facilitate surveys or collection of natural resources or items of cultural significance prior to conducting vegetation clearance. Because UXO would be identified and removed before beginning construction activities and construction personnel would be trained about the hazards associated with unexploded military munitions, potential direct or indirect impacts from encounters with UXO would be minimized and would be less than significant.

**Traffic Incidents**

Potential long-term traffic incident increases would be similar to those discussed under Alternative 2. The potential for increased traffic incidents would be small (5% increase [see Section 4.1.17.2]). Because no high crash frequency intersections are located near NAVMAG and the overall potential long-term increase in the number of traffic accidents as a result of the increase in personnel would be minimal, a less than significant impact from traffic incidents is anticipated on the health and safety of the citizens of Guam.

### 5.4.18 Environmental Justice and the Protection of Children

#### 5.4.18.1 Affected Environment

The affected environment under the NAVMAG (L-Shaped) alternative is considered to be the entire island of Guam, as discussed in Section 4.1.18.1 of this SEIS. The proposed action under Alternative 4 would occur within the southern region of Guam, as defined in Section 4.1.18.1. The villages of Santa Rita, Agat, Umatac, Talofofo, and Yona are within this region.

#### 5.4.18.2 Environmental Consequences

Potential impacts to environmental justice populations from the NAVMAG (L-Shaped) alternative would be to noise, recreation, land acquisition, and public health and safety. The impact analysis discussion provided in the following sections is focused primarily on operational impacts of implementing proposed LFTRC Alternative 4, as LFTRC construction impacts as related to environmental justice would be minimal and short-term, with no measurable effect on Guam’s special-status populations.
Noise

The potential impacts would be the same as Alternative 2.

Recreation

While there are fewer public recreational resources in the south, there are several resources along the coast as described in Section 5.4.7. Potentially-affected resources include Talofofo Falls Park and Hiking Trail.

Construction and/or improvement of access roads on non-federal property would be required to reach the proposed ranges in this alternative. The construction impacts would be temporary and would mostly be limited to construction and earth-moving equipment on public roadways slowing access to recreational resources. There are potential direct impacts from firing range noise, which could lessen visitor enjoyment of publicly-accessible recreational resources in the area of the LFTRC. However the impacts from Alternative 4 would be less than significant due to the lack of existing recreational resources in the areas to be potentially acquired.

Land Acquisition

There would be both beneficial and adverse direct and long-term impacts on adjacent and nearby land uses from the proposed access road/utility easements, as discussed in Section 5.4.6.2, Land and Submerged Land Use. In addition, there would be short- and long-term, direct and indirect significant adverse impacts to land ownership if there is an unsolicited sale of privately-owned land to the federal government for with implementation of Alternative 4. Although there may be landowners who are interested in selling their land, land ownership impacts are considered significant until negotiations have been completed. There would also be other relocation activity and land acquisition, or long-term leases for roadway improvements, to implement this alternative.

Federal regulations regarding land acquisition, such as the DoD’s “net negative” strategy outlined in Section 5.1.6, mitigate for the economic impacts experienced by individual landowners and occupants due to land acquisition. However, due to the extent of the proposed land acquisition and potential increase in federally owned or controlled land on Guam, and a reduction in access to lands of sociocultural and recreational importance, the overall socioeconomic impacts of land acquisition would be significant and adverse.

Tier 1: Are there any minority, low-income, or children populations that would be impacted?

Yes, based on the data provided in Section 4.1.18.1, the private landowners are likely to be racial minorities that live in areas with a higher poverty rate than the U.S.

Tier 2: Are the applicable disadvantaged groups disproportionately affected by the negative environmental consequences of the proposed action(s)?

No, because all of Guam is considered a racial and ethnic minority population, minorities would not experience disproportionately high and adverse effects due to land acquisition. Because federal regulations regarding land acquisition would ensure that significant economic impacts to landowners and occupants do not occur, low-income populations would not experience disproportionately high and adverse effects due to land acquisition. Land acquisition would not result in health and safety risks that would disproportionately impact children. Therefore, Alternative 4 would not result in disproportionate land use or socioeconomic impacts to minority and low-income populations or children as a result of land acquisition.
Public Health and Safety

The potential impacts would be the same as Alternative 2.

5.5 NORTHWEST FIELD LIVE-FIRE TRAINING COMPLEX - ALTERNATIVE 5

Under Alternative 5, the proposed development of a live-fire training range complex would occur at NWF. Details about this alternative are provided in Section 2.5.4.5 and the proposed site is illustrated in Figure 2.5-6.

5.5.1 Geological and Soil Resources

5.5.1.1 Affected Environment

The affected environment for geological and soil resources associated with Alternative 5 is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 3: Geological and Soil Resources, Section 3.1.2: North, pages 3-14 to 3-15), which is summarized below for reference. The proposed reduction in the number of relocating Marines and dependents under the 2012 Roadmap Adjustments does not alter the description of the affected environment for geological and soil resources, but it would reduce some potential impacts to geological and soil resources that were determined to be less than significant or mitigated to less than significant in the 2010 Final EIS, as described in the analysis of environmental consequences for Alternative 5 below.

Alternative 5 would be located in a near-level area close to Ritidian Point in the northern edge of Guam’s limestone structural province (Figure 5.5.1-1). Most of the proposed Alternative 5 footprint stands at an elevation of 500 feet (152 m) above MSL on the top of the limestone plateau. A series of coastal terraces drops down gradually to the west. There are steeper cliffs to the east (Figure 5.5.1-2). All construction for Alternative 5 ranges would take place on the limestone plateau above the cliffs and terraces. The only parts of the project footprint that lie below the plateau are existing USFWS facilities and the proposed construction footprint for the relocated USFS facilities. The elevation at the base of the terraces, where the proposed relocated USFS facilities would be situated, is approximately 60 feet (18 m) MSL. The existing USFWS facilities are located at an elevation of about 15 feet (5 m) MSL. Project-related improvements that would extend onto the beach area would consist only of posting a line of warning signs on the range boundaries and along the beach.

Bedrock underlying the Alternative 5 footprint site is young (Mariana) limestone, the geologic setting for sinkholes (Section 3.1.1.1). Based on available topographic and field data, seven features have been preliminarily identified as sinkholes/depressions that may contain sinkholes within, or on the perimeter of, the proposed Alternative 5 site (Figure 5.5.1-1).

Within the proposed project footprint there are three soil types: Guam Cobbly Clay Loam on the upper plateau (encompassing some or all of the MPMG, KD Pistol, KD Rifle, and MRF ranges); Ritidian-Rock Outcrop Complex on the terraces and cliffs down to the beach (encompassing some or all of the MPMG and Non-standard Small Arms ranges; and Shioya loamy sand on the coastline of the project footprint (Young 1988). For all the soils at the proposed NWF LFTRC site, runoff is slow and the hazard of water erosion is slight (Figure 5.5.1-2). Prime farmland soils, as defined by the USDA, are soils best suited to producing food, seed, forage, fiber and oilseed crops, favorable for economic production and sustained high yield, with minimal inputs of energy and resulting in least damage to the environment (Young 1988). None of the soils in the Alternative 5 footprint are identified by USDA as prime farmland (Young 1988). There is no existing agricultural use, as the area comprises NWF and DOI conservation lands.

The likelihood for landslides to occur in the project footprint is considered low due to the lack of steep slopes (see Figure 5.5.1-2). The maximum reported tsunami wave height reached on Guam was approximately 11.5 feet (3.5 m) MSL in an 1849 tsunami event (GovGuam 2008). The areas proposed for development of Alternative 5 are much higher than the elevation susceptible to tsunamis. However, the existing USFWS facilities are at elevation 15 feet (5 m) MSL, just above the maximum recorded range height of tsunami waves. The Alternative 5 footprint is not subject to liquefaction because it is underlain by consolidated limestone bedrock that does lose not cohesiveness in response to ground shaking during an earthquake (see Figure 5.5.1-1). The limestone bedrock in the area of Alternative 5 presents a potential hazard of surface instability and collapse due to sinkholes.

5.5.1.2 Environmental Consequences

Construction

Potential geology and soil impacts addressed in this section are limited to elements of the proposed action that could affect onshore landforms or that could be affected by geologic hazards. Potential soil contamination issues are addressed in Section 5.5.16.2 of this SEIS (Hazardous Materials and Waste).

Construction impacts associated with the HG Range at Andersen South would be similar to described under Alternative 1 in Section 5.1.1.2 of this SEIS.

Construction activities for Alternative 5 would be similar to those described for Alternative 1, without realignment of Route 15. Similar to Alternative 1, there would be no stream re-routing for construction of Alternative 5. Earthwork would include 2,047,295 yd³ (1,565,270 m³) of cut and 1,932,392 yd³ (1,477,420 m³) of fill, resulting in a net of 114,903 yd³ (87,850 m³) of cut (DON 2103a). Alternative 5 would involve the lowest amount of excavation of all the action alternatives but Alternative 2 (Alternative 3 would involve the greatest; Alternative 2 would require the least). Within the Alternative 5 footprint there are major differences in elevation in the area planned for construction of the MPMG Range. There would be substantial changes to surface elevation for construction of the MPMG Range (DON 2013b). Due to the greater differences in elevation in the planned Alternative 5 MPMG Range area, about 1.5 times as much excavation and fill would be needed overall to construct Alternative 5 compared with Alternative 2. Because of the major elevation changes, the substantial alteration of the surrounding landscape, and the amount of excavation, filling and contouring that would occur, construction of NWF LFTRC Alternative 5 is expected to have a significant direct, long-term impact on topography. Potential mitigation is not considered feasible for this impact because smaller cut/fill volumes would not provide the necessary level surfaces for the referenced ranges. This significant impact to topography would occur with implementation of any LFTRC alternative except Alternative 2, which would involve the least amount of cut and fill (i.e., the impact would be similar for all alternatives except Alternative 2).

Construction of the HG Range would involve 8,894 yd³ (6,800 m³) of cut and 12,641 yd³ (9,665 m³) of fill, for a net of 3,747 yd³ (2,865 m³) of fill. The 114,903 yd³ (87,850 m³) of net cut generated by construction of the other Alternative 5 ranges would provide sufficient additional fill to supply the need at the HG Range.

If the existing USFWS facilities are demolished, existing surface elevations would not be changed substantially, so this component of Alternative 5 would have a less than significant direct, long-term impact with respect to topography.

Construction for the Alternative 5 ranges and the relocated USFWS facilities would occur in soil and topographical conditions that are similar to Alternative 1 with respect to the potential for increased soil
erosion. Under Alternative 5, the same engineering controls required by 22 GAR, Chapter 10 Guam Soil Erosion and Sediment Control Regulations would be implemented as BMPs to minimize erosion within the project construction footprint, as for Alternative 1. Similar to Alternative 1, there would be no stream re-routing involved with construction of Alternative 5.

In addition, construction activities associated with Alternative 5 would comply with the Construction General Permit. Potential construction-specific stormwater BMPs would be implemented in compliance with the Construction General Permit. Construction-specific stormwater BMPs would provide erosion and sediment control during the construction period, generally by employing on-site measures that reduce the flow of stormwater and minimize the transport of soils and sediment off-site. Fill material would be generated on-site, whenever possible. In addition, roadway-specific BMPs, as identified in the most recent CNMI and Guam Stormwater Management Manual, would be included in the planning, design, and construction of all roadways and facilities. Through compliance with 22 GAR Chapter 10 and the Construction General Permit and implementation of roadway stormwater BMPs, and because the rate of erosion and soil loss would not be substantially increased, direct, short-term impacts to soils from erosion during construction of Alternative 5 (including the relocated USFWS facilities) and possible demolition of the existing USFWS facilities would be less than significant. In addition, no indirect, short-term impacts associated with soil erosion are expected.

The soils that would be disturbed by construction of Alternative 5 are not identified as prime farmland and there is no existing agricultural use. Therefore, disturbance of soil during construction of Alternative 5 would have no direct or indirect impact to agricultural soils.

There are seven features that may contain sinkholes within, or on the perimeter of, the Alternative 5 footprint (see Figure 5.5.1-1). For any sinkholes discovered before or during construction, BMPs would include compliance with 22 GAR Chapter 10 § 10106F. In order to ensure compliance with 22 GAR Chapter 10 § 10106F, BMPs would be modified or an environmental and hydrogeologic assessment must be performed to ensure adverse effects will not result, including but not limited to the displacement of groundwater, interference with well production, significant changes to groundwater recharge, flooding, or the threat or introduction of any pollutant to groundwater. After a preferred alternative is selected and the ROD is signed for the proposed project, final design work would begin for the preferred alternative site. A geotechnical study, including subsurface borings, would be conducted to determine whether the depressions on the site contain sinkhole, and whether there are additional sinkholes not evident from the surface. Hydrogeological studies would be conducted to confirm groundwater flow at the site as well. The geotechnical and hydrogeological studies would be coordinated with the GEPA to design and implement an appropriate analysis. These studies would be part of the final design process and would take place before any construction begins. With implementation of these BMPs, and since no sinkholes would be filled that would adversely affect site drainage, no adverse impacts to sinkholes would occur. Therefore, direct, short-term impacts to sinkholes due to construction of Alternative 5 would be less than significant.

Hazards associated with earthquakes, fault rupture and slope instability would be minimized by adherence to UFC 3-310-04 Seismic Design of Buildings dated June 1, 2013 (USACE 2013). The consolidated limestone bedrock underlying Alternative 5 footprint (including the USFWS relocation) is not vulnerable to liquefaction, and there would not be a change to soil and/or bedrock conditions that would increase vulnerability to a geologic hazard. If the existing USFWS facilities are demolished, there would be a temporary potential for site workers to be exposed to hazards associated with a tsunami, should one occur. As a BMP to minimize such hazards, the contractor would be required to provide a site-specific health and safety plan that includes notifying workers of the potential tsunami hazard, and communications and
evacuation procedures to be followed to ensure that all site personnel are alerted to an approaching tsunami and move to safety. As stated in the previous paragraph, 22 GAR Chapter 10 § 10106F requires that for sinkholes within the project development footprint that would be modified or used, an environmental and hydrogeologic assessment must be performed to ensure adverse effects will not result. Compliance with these regulations would minimize potential geologic hazards associated with sinkholes. With implementation of procedures to minimize worker exposure to potential tsunami hazards, compliance with 22 GAR Chapter 10 § 10106 and adherence to UFC 3-310-04, construction of Alternative 5 would have less than significant direct and indirect short-term impacts with respect to geologic hazards.

**Operation**

Operational impacts associated with the HG Range at Andersen South would be similar to those described under Alternative 1 in Section 5.1.1.2 of this SEIS.

Operations at the relocated USFWS facilities would be recreational and administrative and as such would not typically involve activities that would disturb the ground surface, or cause or increase soil erosion. An erosion control plan would be required for maintenance activities, such as occasional utility maintenance, to avoid and minimize potential erosion.

Alternative 5 operations and relocated USFWS facilities would not alter topography post construction, so no direct or indirect impact to topography would occur.

The firing range activities and conditions that may directly cause or increase naturally occurring soil erosion during the operational phase would similar to Alternative 1 and are described in Section 5.1.1.2 of this SEIS. Similar to Alternative 1, under Alternative 5 the significant long-term changes to topography during construction of the MPMG Range are relevant when considering a potential for increase in soil erosion.

The area of impervious surfaces that would be constructed for the ranges and associated infrastructure (range buildings, roads, and parking areas) would be approximately 29.6 acres (12.0 ha) total (Appendix F) including about 28.7 acres (11.6 ha) for Alternative 5 and about 0.9 acre (0.4 ha) for the HG Range. There would be a minor increase in runoff from the new impervious surface area as compared with existing conditions. Stormwater infrastructure improvements included as part of the proposed action would incorporate LID measures and BMPs to minimize soil erosion from increased runoff. Where possible, stormwater flow paths would continue to mimic pre-development flows through area topography. During the operations phase, stormwater BMPs that would be implemented to minimize and control runoff would also minimize soil erosion.

The range complex would be managed in accordance with current Marine Corps range management policies and procedures, which are designed to ensure the safe, efficient, effective, and environmentally sustainable use of the range area. A thorough explanation of Marine Corps range management is detailed in the 2010 Final EIS (Volume 2, Chapter 2: Description of Proposed Action and Alternatives, Section 2.3.1.4: Firing General Military Skills, pages 2-55 to 2-59). Marine Corps range management policies and procedures include procedures for removing expended rounds from live-fire ranges with impact berms (estimated at a minimum of 5 year intervals), managing stormwater, controlling erosion, maintaining vegetation on berms and drainage ways and turf on the range, and restricting vehicular activities to designated/previously identified areas. Range roads would be maintained to minimize erosion.
As indicated in the 2010 Final EIS, the NWF project area overlies the Finegayan and Agafa-Gumas basins of the NGLA. Because the NGLA is used as a source for drinking water, prior to the construction of the ranges, both a site inspection and a site assessment (including installation of four wells at the LFTRC site with associated groundwater sampling and aquifer testing as needed), as well as actual munitions loading data, would be provided to the Marine Corps’ REVA and ORC programs. These programs would use the site specific data to determine the appropriate frequency of monitoring and range clearance.

Under the REVA Program, site specific data would be used to evaluate the potential for MCs to reach potential receptors. This would allow the REVA program to determine whether follow-on actions would be required (e.g., sampling, additional studies) and the frequency of any further evaluations. The REVA assessment would use conservative assumptions and available site specific information to determine if modeling can be performed for lead components. Monitoring of the ranges for MCs migrating off-range would be based on the outcome of the REVA assessment. REVA assessments would begin in the first year of operation and would then be conducted at a minimum every 5 years.

The ORC program would not only consider the site-specific and REVA data but also safety and sustainability considerations in its assessment to determine the required frequency of range clearance.

Munitions constituents associated with small arms ammunition commonly used at operational ranges include lead, antimony, copper, and zinc. Lead is the primary munitions constituent indicator for small arms ranges because lead is the most prevalent (by weight) constituent associated with small arms ammunition. No specific quantitative conclusions can be made regarding the fate and transport of lead, because lead is geochemically specific regarding its mobility in the environment. Site-specific conditions are required (i.e., geochemical properties) in order to quantitatively assess lead migration. Site-specific geochemical properties are only identified via sampling and cannot be observed physically. Without site-specific physical and chemical characterization, lead cannot effectively be modeled using fate and transport modeling. The scientific community has established that metallic lead (such as recently fired, un-weathered bullets and shot) generally has low chemical reactivity and low solubility in water and is relatively inactive in the environment under most ambient or everyday conditions. However, a portion of lead depositied on a range may become environmentally active if the right combination of conditions exists.

As indicated in the above paragraphs, a site inspection and site assessment will be completed at the range and the site-specific information provided to the REVA Manager. The REVA manager will utilize this site-specific information in their assessments of the range, which begin the first year of range operation. Assessing small arms ranges first involves defining and documenting its physical and environmental conditions, as well as how the range is utilized and maintained. The assessment process involves a review of possible factors that can influence the potential for lead to migrate off range including range use and management (source), surface water, groundwater and soil conditions, pathways and receptors (including but not limited to people, sensitive and endangered species). Upon review, if factors or a combination of factors are found to exist that would indicate possible lead migration, REVA program managers consider sampling appropriate media, identifying and implementing BMPs adjustments, or taking other steps as required.
The DON will investigate additional technologies that could assist with range design and minimizing potential impacts (specific technologies or brands were not mentioned to ensure the full range of BMPs are considered). Prior to the construction of the range, the DON will perform a site survey/inspection to inform range design activities, to include evaluating the optimal site grading and any necessary soil amendments to minimize range constituent migration. Appropriate BMPs will be evaluated and incorporated into the design and construction of the range to minimize the off-site migration of stormwater runoff and reduce the infiltration of MCs (e.g. vegetation buffers, pH adjustment of soil and water quality/quantity BMPs). Designs will subsequently be coordinated and approved through Head, Range Design and Safety, Commanding General Marine Corps Combat Development Command.

There would be minor ground disturbance associated with utility maintenance. Construction stormwater BMPs would be implemented during maintenance activities to minimize and control runoff on-site and minimize potential effects of erosion.

A potential indirect impact of firing range operations includes the possibility of live ammunition causing wildland fires. As a BMP and in accordance with range safety protocols, a Range Fire Management Plan would be prepared, based on the DON’s Wildland Fire Management Plan (USFS 2008). It would include protocols for monitoring fire conditions and adjusting training as needed. Units undergoing training at the ranges would be briefed by range control on requirements suitable to the conditions of the day and protocols should a fire occur (e.g., specifying how the range would shut down and how fire suppression action would be taken). With these measures, potential wildfires caused by the live ammunition would be unlikely. Effects to soils from erosion associated with wildfires associated with operation of Alternative 5 would be minimal and direct and indirect impacts would be less than significant.

With implementation of Marine Corps range management policies and procedures, fire suppression and potential mitigation measures, and stormwater BMPs (for ranges and ground-disturbing maintenance) less than significant direct and indirect long-term impacts to soils from erosion would occur due to Alternative 5 range operations.

No prime farmland is identified within the Alternative 5 project footprint. Therefore, there would be no direct or indirect long-term impact to agricultural soils as a result of Alternative 5 operations.

The BMPs for sinkholes would be implemented in the event that maintenance activities should involve sinkholes or their immediate perimeter, so no adverse impacts to sinkholes would occur. Therefore, Alternative 5 operations impacts would have less than significant direct, long-term impacts to sinkholes.

Hazards associated with earthquakes, fault rupture and slope instability would be minimized by adherence to UFC 3-310-04 Seismic Design of Buildings dated June 2013 (USACE 2013) during project design and construction, so direct and indirect long-term impacts with respect to seismic hazards would be less than significant. The consolidated limestone bedrock underlying the Alternative 5 site is not vulnerable to liquefaction. Once constructed, Alternative 5 and the USFWS facilities would be inland and higher than the elevation prone to tsunamis, so would not be susceptible to inundation. There would not be a change to soil and/or bedrock conditions that would increase vulnerability to a geologic hazard. Implementation of sinkhole BMPs would minimize potential geologic hazards associated with sinkholes. Therefore, operation of Alternative 5 would have less than significant direct and indirect long-term impacts with respect to geologic hazards.
5.5.2 Water Resources

5.5.2.1 Affected Environment

The affected environment for water resources at NWF is described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.1.2.1: Andersen AFB, page 4-25). A summary of site conditions for Alternative 5 is provided in Appendix F. The affected environment for the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.2.1 of this SEIS.

Surface Water

As indicated in the 2010 Final EIS, there are no surface water resources in the project area and there are no 100-year or 500-year flood zones identified within the proposed construction area (Figure 5.5.2-1).

Groundwater

As indicated in the 2010 Final EIS, the NWF project area overlies the Finegayan and Agafa-Gumas basins of the NGLA. There are several depressions/sinkholes located within and in the vicinity of the project area (Figure 5.5.2-1).

Nearshore Waters

Nearshore waters around the NWF project site include Ritidian Point and beach. Use of this area is primarily conservation with the Guam NWR Ritidian Unit being important for biological resources. There is also recreational use in the area (see Sections 5.5.8, Terrestrial Biological Resources and 5.5.7, Recreational Resources, respectively, in this SEIS for more information). As indicated in the 2010 Final EIS, nearshore waters are classified as having M-1 water quality in this area. The SDZ would extend over nearshore waters, including the USFWS Ritidian Point Reserve (Figure 5.5.2-1).

Wetlands

As discussed in the 2010 Final EIS, there are no wetlands in the project area (Figure 5.5.2-1).

5.5.2.2 Environmental Consequences

Construction

General construction impacts to water resources under Alternative 5 would be similar to those described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.1: North, pages 4-84 to 4-88) and under Alternative A in Section 4.1.2.2 of this SEIS. Under Alternative 5, there would be construction activities associated with the proposed LFTRC ranges in the NWF and HG Range project areas. Construction impacts associated with the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.2.2 of this SEIS.

Similar to Alternative A, Alternative 5 would occur in an area that does not contain any waters of the U.S. but would comply with the Construction General Permit, as described under Alternative A. Construction under Alternative 5 would result in the potential for short-term increases in stormwater runoff and erosion. However, through compliance with the Construction General Permit and Program SWPPP and implementation of a site-specific SWPPP and associated erosion control, runoff reduction, and sediment removal BMPs (see Table 4.1.2-2), these effects would be minimized and off-site transport of stormwater runoff would be unlikely unless during extreme weather events (i.e., typhoons). Specifically, the site-specific SWPPP would identify appropriate BMPs for the site that would serve to contain runoff and sediment on-site by reducing the flow rate of runoff and thereby minimize transport of suspended sediment through settling and promote infiltration of runoff.
Figure 5.5.2-1
Water Resources in the Vicinity of NWF LFTRC Alternative 5

Sources: FEMA 2007; USGS 2003; NAVFAC Pacific 2013; WERI 2001
Surface Water

No buildings/structures would be constructed in the 100-year or 500-year flood zones and no surface waters are located within or near the proposed construction areas under Alternative 5. Given compliance with the Construction General Permit and implementation of a Program SWPPP and site-specific SWPPP, off-site transport of stormwater runoff, sediment, or other pollutants would be unlikely. Therefore, construction activities associated with Alternative 5 would result in no short-term impacts to surface waters.

Groundwater

Construction activities under Alternative 5 would include stormwater runoff protection measures that would also serve to protect groundwater quality. By adhering to the provisions of the Construction General Permit and implementing BMPs associated with addressing site- and activity-specific water resource protection requirements, there would be a reduction in stormwater pollutant loading potential and thus a reduction in pollution loading potential to the underlying groundwater basins of the NGLA. As described under Alternative A, an environmental and hydrogeologic assessment for the selected alternative would be performed for sinkholes within the project development footprint to ensure adverse effects to groundwater resources would not occur. Given stormwater runoff protection measures (i.e., compliance with Construction General Permit requirements and implementation of BMPs) and the environmental and hydrogeologic assessment for sinkhole protection (if encroachment is unavoidable), construction activities associated with Alternative 5 would result in less than significant short-term, direct or indirect impacts to groundwater.

Nearshore Waters

The project area would be located approximately 0.04 mile (0.06 km) from nearshore waters (see Figure 5.5.2-1). Given compliance with the Construction General Permit and implementation of a Program SWPPP and site-specific SWPPP, off-site transport of stormwater runoff, sediment, or other pollutants would be unlikely (see discussion of BMPs under Construction). In addition, vegetative cover between the construction area and the edge of the steep cliffline and the shoreline would provide an additional buffer and protection from stormwater runoff or sediment reaching nearshore waters. Given adherence to the provisions of the Construction General Permit and implementation to BMPs, it is expected that stormwater runoff, sediment, or other pollutants would not discharge to nearshore waters. Therefore, construction activities associated with Alternative 5 would result in no impacts to nearshore waters.

Wetlands

No wetlands are located in or near the construction areas associated with Alternative 5. Therefore, construction activities associated with Alternative 5 would result in no impacts to wetlands.

Operation

Alternative 5 would incorporate the concept of LID in the final planning, design, and permitting of the stormwater runoff and drainage design as described in the 2010 Final EIS (Volume 2, Chapter 4: Water Resources, Section 4.2.2.1: North, pages 4-85 to 4-87) and under Alternative A in Section 4.1.2.2 of this SEIS. Operation impacts associated with the HG Range at Andersen South would be the same as described under Alternative 1 in Section 5.1.2.2 of this SEIS.
Under Alternative 5, there would be a minor increase in the area of impervious surface as a result of training buildings and complexes, which would result in an associated increase in stormwater discharge intensities and volume. However, increases in stormwater runoff from increased impervious area would be accommodated through the implementation of LID measures and BMPs. Alternative 5 would potentially increase the amount of POLs, hazardous waste, herbicides, pesticides, and fertilizers being stored, transported, and utilized on the proposed facilities. However, impacts from these contaminants would be minimized with the implementation of a SWPPP, SWMP, and SPCC plan.

Alternative 5 would include implementation of the REVA program and range management preventative measures (i.e., vegetation, pH adjustment, LID). As listed in Section 2.8 of this SEIS, the BMPs would reduce the potential for contaminants to migrate off-site. In addition, the DoD would investigate additional technologies that could assist with range design and management to minimize potential impacts. Available baseline data regarding range site conditions would be reviewed and verified prior to range construction and quarterly monitoring would occur during operations to verify the effectiveness of BMPs. For each range, water quality treatment strategies would be selected to achieve reductions of non-point source pollutants to meet the same water quality requirements as identified under Alternative A in Section 4.1.2.2 of this SEIS.

Surface Water

No surface waters are located within the Alternative 5 project area and the implementation of an appropriate and comprehensive stormwater management plan utilizing a LID approach and range management BMPs would ensure that there would be no increase in off-site transport of excess stormwater runoff, sediment, or other pollutants for up to the 25-year design storm event. Therefore, Alternative 5 would result in no impacts to surface water.

Groundwater

Range operations under Alternative 5 have the potential to leach MCs to the water. However, range management BMPs would be implemented, as listed in Section 2.8 of this SEIS. As indicated in the 2010 Final EIS, the NWF project area overlies the Finegayan and Agafa-Gumas subbasins of the NGLA. Because the NGLA is used as a source for drinking water, prior to the construction of the ranges, both a site inspection and a site assessment (including installation of four wells at the LFTRC site with associated groundwater sampling and aquifer testing as needed), as well as actual munitions loading data, would be provided to the Marine Corps’ REVA and ORC programs. These programs would use the site specific data to determine the appropriate frequency of monitoring and range clearance.

Under the REVA Program, site specific data would be used to evaluate the potential for MCs to reach potential receptors. This would allow the REVA program to determine whether follow-on actions would be required (e.g., sampling, additional studies) and the frequency of any further evaluations. The REVA assessment would use conservative assumptions and available site specific information to determine if modeling can be performed for lead components. Monitoring of the ranges for MCs migrating off-range would be based on the outcome of the REVA assessment. REVA assessments would begin in the first year of operation and would then be conducted at a minimum every 5 years.
The ORC program would not only consider the site-specific and REVA data but also safety and sustainability considerations in its assessment to determine the required frequency of range clearance.

Munitions constituents associated with small arms ammunition commonly used at operational ranges include lead, antimony, copper, and zinc. Lead is the primary munitions constituent indicator for small arms ranges because lead is the most prevalent (by weight) constituent associated with small arms ammunition. No specific quantitative conclusions can be made regarding the fate and transport of lead, because lead is geochemically specific regarding its mobility in the environment. Site-specific conditions are required (i.e., geochemical properties) in order to quantitatively assess lead migration. Site-specific geochemical properties are only identified via sampling and cannot be observed physically. Without site-specific physical and chemical characterization, lead cannot effectively be modeled using fate and transport modeling. The scientific community has established that metallic lead (such as recently fired, un-weathered bullets and shot) generally has low chemical reactivity and low solubility in water and is relatively inactive in the environment under most ambient or everyday conditions. However, a portion of lead deposited on a range may become environmentally active if the right combination of conditions exists.

As indicated in the above paragraphs, a site inspection and site assessment will be completed at the range and the site-specific information provided to the REVA Manager. The REVA manager will utilize this site-specific information in their assessments of the range, which begin the first year of range operation. Assessing small arms ranges first involves defining and documenting its physical and environmental conditions, as well as how the range is utilized and maintained. The assessment process involves a review of possible factors that can influence the potential for lead to migrate off range including range use and management (source), surface water, groundwater and soil conditions, pathways and receptors (including but not limited to people, sensitive and endangered species). Upon review, if factors, or a combination of factors are found to exist that would indicate possible lead migration, REVA program managers consider sampling appropriate media, identifying and implementing BMPs adjustments or taking other steps as required.

Additionally, the proposed ranges at NWF would be located down-gradient from and approximately 2 miles (3 km) from the nearest active groundwater well (AF-5) (Figure 5.5.2-2). HQMC also commissioned a study on the effects of pumping and drought on the NGLA (USGS Scientific Investigations Report 2013-5216: The Effects of Withdrawals and Drought on Groundwater Availability in the Northern Guam Lens Aquifer, Guam). Information from this report will be used to adjust pumping rates in order to avoid increased salinization and reversal of groundwater flow patterns. The overall flow of groundwater in this area would not be altered by proposed future pumping rates, groundwater would not flow towards drinking water production wells. Given stormwater runoff protection measures (i.e., implementation of LID, BMPs, operation and maintenance programs) and location of range activities in relation to active wells, operations associated with Alternative 5 would result in less than significant long-term, direct or indirect impacts to groundwater.
Figure 5.5.2-2
Groundwater Wells and Flow Direction in the Vicinity of NWF LFTRC Alternative 5

**Nearshore Waters**

Under Alternative 5, proposed operations would be in compliance with the stormwater runoff protection measures identified above that would ensure that there would be no increase in off-site transport of stormwater runoff, sediment, or other pollutants to nearshore waters for up to the 25-year design storm event. In addition, vegetative cover between the project area and the edge of the steep cliffline and the shoreline would provide an additional buffer and protection from stormwater runoff or sediment reaching nearshore waters. Therefore, there would be no impacts to nearshore waters from stormwater runoff associated with increased impervious areas and training activities under Alternative 5.

The SDZ associated with the Alternative 5 LFTRC ranges would overlap nearshore waters by approximately 3,059 acres (1,238 ha) (see Figure 5.5.2-1). There would be a very small chance that an expended projectile would fall outside of the range footprint, within the SDZ. There would be an even smaller chance for an expended projectile to fall within the nearshore water portion of the SDZ. Due to the small number of potential projectiles that could fall into the nearshore SDZ and the relatively small size of the projectiles, potential impacts to nearshore water quality from these projectiles would be negligible under Alternative 5.

**Wetlands**

No wetlands are located within or near the proposed operational areas under Alternative 5. Therefore, operations associated with Alternative 5 would result in no impacts to wetlands.

5.5.3 **Air Quality**

5.5.3.1 **Affected Environment**

Because of the proximity to AAFB, ambient air quality conditions around the site for Alternative 5 are affected primarily by various operational activities occurring at the base from stationary and mobile emissions sources, including aircraft, vehicles along Route 3A, and various stationary boilers and generators, as discussed in Section 4.3.3.

5.5.3.2 **Environmental Consequences**

The construction activities associated with Alternative 5 would be similar to Alternative 1, with the exception of site location. Therefore, the predicted construction activity annual emissions would be the same as Alternative 1, as summarized in Table 5.1.3-2, and are well below the significance criterion of 250 tpy.

The hot-spot air quality impacts during both construction and operational phases would be similar to Alternative 1, as discussed in Section 5.1.3; resulting in less than significant short- and long-term hot-spot air quality impacts.
5.5.4 Noise

5.5.4.1 Affected Environment

Existing noise levels at NWF are composed of airfield operations in flight tracks going to and from AAFB, aviation training at NWF, and ground-based training. AAFB’s most recent AICUZ study was funded by NAVFAC Southwest and was completed in 2014. As discussed in the 2010 Final EIS (Volume 2, Chapter 6: Noise, Section 6.1.2: Affected Environment, pages 6-10), aviation training activities at NWF include familiarization training and field carrier landing practice for helicopters and airlift operations by H-60, H-46, H-53, V-22, H-1 and C-130 aircraft. Noise contours from airfield operations operating from AAFB are shown on Figure 4.1.4-1 in Chapter 4 of this SEIS. Because aircraft operations at NWF are not frequent, amounting to approximately 80 operations per year, an AICUZ study specifically for NWF has not been prepared. However, single event SELs due to helicopters operating directly overhead can reach 94 dBA at 100 feet (30 m) but operations occur in the interior of NWF and generally attenuate to below 70 dBA at the property line and up to 76 dB with four helicopters operating simultaneously. A number of flight paths for aircraft operating from AAFB occur over NWF and although the AICUZ noise contours of 65 dBA or greater do not reach NWF, jet aircraft such as F-22 and F/A-18 operating along these flight tracks can generate single event SELs in excess of 100 dBA. In particular, departure routes 4RD2 and 4RD3 are about 1 mile (1.6 km) from Ritidian Point and an SEL of up to 101 dBA from an F-22 can be experienced at Ritidian Point.

In addition to aviation training, ground-based training occurs for force protection using pyrotechnics, ground burst simulators, smoke grenades, and 40-pound cratering charges. Noise levels from these operations are within Noise Zones 2 and 3 and are confined within NWF. These noise events are dominated by the demolition charges which are impulsive sounds and generate CDNL of less than 62 dBC at the boundary of NWF. The 2010 Final EIS (Volume 2, Chapter 6: Noise, Section 6.1.2: Affected Environment, pages 6-11 to 6-12) describes ground-based training in further detail.

5.5.4.2 Environmental Consequences

Construction

Similar to Alternatives 2, 3, and 4, there would be no impact due to construction noise under Alternative 5 because construction activities would be within NWF and away from any sensitive human receptors. Construction areas along the access road to Ritidian Point would be approximately 0.25 mile (0.4 km) away from the nearest receptors, a distance that is far enough away from the source of construction noise such that there would be minimal noise effects on receptors.

Operation

The noise modeling results for Alternative 5 (Army 2013) are shown on Figure 5.5.4-1. Under Alternative 5, the Zone 2 noise contours cover approximately 48 onshore acres (19 ha) beyond the boundaries of DoD land at NWF or DOI land onto private property near the entrance to the Ritidian Unit of the Guam NWR and Jinapsan Beach. Offshore, Zone 2 would cover approximately 389 acres (157 ha) but no Zone 3 contours extend offshore. No residents would be affected by Zones 2 and 3 noise levels because there are no homes located under any of the contours.
Figure 5.5.4-1
Small Arms ADNL Noise Zones for NWF LFTRC Alternative 5

Source: NAVFAC Pacific 2013
For the NWF alternative, there are no inhabited homes located under the compatible Zone 1 contours as well. Table 5.5.4-1 lists the Noise Zones and the associated acreage affected within each zone. There are a few uninhabited homes near Jinapsan Beach, but these homes would be within Noise Zone 1, although one house appears to be close to Zone 2. Noise contours that result from Joint Service users at the LFTRC would fall within the contours shown, because the noise contours were calculated as an average busy day and the use by other services would be more infrequent and less intense than Marine Corps usage.

Notes:  
1 Zone 1 is not listed because all land uses are compatible within Zone 1.  
2 On-base includes end-state restricted access areas.  
Source: Army 2013, NAVFAC Pacific 2013.

Although there would be noise due to LFTRC activities combined with the existing aviation and ground-based training, noise is modeled independently because noise from each noise source (aircraft, explosives, and small arms) is estimated using different models for each source. Explosion noise from ground-based training is estimated using the C-weighted metric, and mathematically it cannot be added to the small arms noise contours. Qualitatively, none of the noise-generating activities would create incompatible land use impacts and adversely affect individual human populations. Collectively, the noise-generating activities would not likely combine to create incompatible land use because noise from each activity is low at the nearest receptors.

In addition, the nearest noise receptors are located at the base of the cliff, while the noise-generating activities would be on the bluff above with the land providing a natural sound barrier. However, officially recognized noise models for small arms range noise are unable to account for the presence of a steep cliff northwest of the proposed LFTRC. Actual noise levels are anticipated to be 5-15 dBA less than the modeled noise levels below the cliffline (personal communication, M. Downing, Blue Ridge Research and Consulting, February 2014).

Under Alternative 5, no people would be impacted by Zone 2 or 3 noise levels because there are no residences within these zones. Military members assigned to the Pacific Regional Training Center (PRTC) and Joint Threat Emitter that work and/or live at NWF are not located in Zones 2 or 3 and would not be exposed to incompatible noise levels. Potential noise effects on Joint Threat Emitter equipment are under review by DoD. There would be no direct impacts due to live-fire training noise under this alternative and none of the noise significance criteria stated in the Marine Corps Guidance memo for land use and noise exposure would be exceeded (Marine Corps 2005). There would be no direct or indirect impacts because none of the impact assessment criteria related to potential noise impacts would be exceeded. As described in Section 5.1.4.2, noise levels at the HG Range would remain within Andersen South and not impact any residences. In summary, there would be no residences/households affected by
noise resulting from implementation of Alternative 5 and, consequently, no significant noise impacts would occur.

5.5.5 Airspace

5.5.5.1 Affected Environment

The existing airspace conditions for Alternative 5 would be the same as described for Alternative 1 (see Section 5.1.5.1). Detailed information on military and civilian air traffic associated with AAFB and Guam International Airport, respectively, is provided in the 2010 Final EIS (Volume 2, Chapter 7: Airspace, Section 7.1: Military Air Traffic, pages 7-8 to 7-10).

5.5.5.2 Environmental Consequences

Construction

No changes to airspace would be required during construction of the LFTRC under Alternative 5, and construction activities would not be expected to conflict or interfere with the use or management of existing airspace in the vicinity. Therefore, construction of the LFTRC under Alternative 5 would have no impact on airspace.

Operation

Figure 5.5.5-1 depicts the proposed Restricted Area associated with Alternative 5. This SUA would be needed to contain the vertical hazard associated with the proposed live-fire training. The proposed NWF Option of R-7202 Guam would be structured as an overall airspace area with three distinct segments that could be operated individually or as a whole. The boundary coordinates of the overall R-7202 Restricted Area would begin at:

- lat.13°41'42"N., long.144°52'9"E
- to lat.13°40'48"N., long.144°54'4"E
- to lat.13°38'13"N., long.144°52'43" E
- to lat.13°37'56"N., long.144°52'22"E
- to lat.13°38'36"N., long.144°51'5"E
- to the point of beginning

Segment A of the proposed R-7202 Guam would begin at:

- lat.13°41'42"N., long.144°52'9"E
- to lat.13°40'48"N., long.144°54'4"E
- to lat.13°39'52"N., long.144°53'35"E
- to lat.13°40'20"N., long.144°52'41"E
- to lat.13°40'3"N., long.144°52'31"E
- to lat.13°40'3"N., long.144°52'14"E
- to lat.13°39'7"N., long.144°52'15"E
- to lat.13°38'11"N., long.144°51'54"E
- to lat.13°38'36"N., long.144°51'5"E
- to the point of beginning
Figure 5.5.5-1
Proposed SUA Associated with LFTRC Alternative 5

Source: NAVFAC Pacific 2013
Segment B of the proposed R-7202 Guam would begin at:

- lat.13°40'20"N., long.144°52'41"E
- to lat.13°39'52"N., long.144°53'35"E
- to lat.13°39'27"N., long.144°53'22"E
- to lat.13°38'3"N., long.144°52'9"E
- to lat.13°38'11"N., long.144°51'54"E
- to lat.13°39'7"N., long.144°52'15"E
- to lat.13°40'3"N., long.144°52'14"E
- to lat.13°40'3"N., long.144°52'31"E
- to lat.13°40'3"N., long.144°52'14"E
- to lat.13°40'3"N., long.144°52'31"E
- to the point of beginning

Segment C of the proposed R-7202 Guam would begin at:

- lat.13°38'3"N., long.144°52'9"E
- to lat.13°39'27"N., long.144°53'22"E
- to lat.13°38'13"N., long.144°52'43"E
- to lat.13°37'56"N., long.144°52'22"E
- to the point of beginning

Altitudes for all proposed segments, times of use, and controlling and using agencies for this Restricted Area SUA would be the same as described in Section 5.1.5.2 for LFTRC Alternative 1 at Route 15. The proposed CFA associated with the HG Range at Andersen South would be the same as described in Section 5.1.5.2 and depicted in Figure 5.1.5-4.

Section 3.5.3.1 identifies the potential impacts to airspace from implementation of the LFTRC alternatives. Due to the proximity of Alternative 5 to AAFB, there would be additional concerns. The AAFB VFR reporting point at Ritidian Point (also known as “Northpoint”) would be located within the proposed Restricted Area. This proposed Restricted Area would also encumber certain instrument approach procedures at AAFB, portions of the AAFB radar traffic pattern, and circling procedures for Category E aircraft for both AAFB runways. Minimum/emergency safe sectors and altitudes would require updating. In addition, when the LFTRC was active, coordination would be required to conduct simultaneous operations at the NWF landing zone and drop zone due to overflight restrictions imposed by the LFTRC to the north and the MSA to the south. Potential mitigation measures for these impacts are subject to ongoing actions between the Marine Corps, Air Force, and FAA.

Operational activities under Alternative 5 have the potential for direct impacts to aviation due to the following:

- AAFB instrument approach procedures.
- IFR/VFR traffic flows and terminal operations.
- Known but uncharted high volume routes.
- AAFB airspace.
- Existing SUA/Terminal Radar Service Area.
- VFR Reporting Points.
The FAA stated in the preliminary Airspace Feasibility Assessment that Alternative 5 is feasible (FAA 2013). Based on FAA’s review and the OPNAV assessment, this alternative would have less than significant direct impacts to civil aviation and the national airspace system. However, it would have potentially significant impacts to military air operations in and around AAFB that require deconfliction, and some mitigation would still be required to lessen impacts on AAFB operations. The Commanders of Pacific Air Forces and Marine Forces Pacific have agreed to a memorandum of agreement detailing specific mitigation measures. As detailed in Table 5.7-1, operational impacts to civil aviation under Alternative 5 would be the least of all alternatives.

5.5.6 Land and Submerged Land Use

5.5.6.1 Affected Environment

A large portion of the Ritidian Unit of the Guam NWR would be affected by Alternative 5. The Guam NWR is federal land. The Ritidian Unit of the Guam NWR is comprised of 370.6 acres (150.0 ha) of federal terrestrial land and 401.5 acres (162.5 ha) of federal submerged land under the custody and control of DOI, which has administrative responsibility over the property to meet the DOI mission. The SDZs would affect the federally owned submerged lands under the custody and control of DON north of the Ritidian Unit of the Guam NWR (Figure 5.5.6-1).

There are two private land parcels on the coastlines located east and southwest of the Ritidian Unit of the Guam NWR. The proposed Alternative 5 footprint encumbers the majority of the Ritidian Unit of the Guam NWR and is adjacent to the eastern private land.

All LFTRC alternatives include an HG Range at Andersen South, the affected environment and impacts of which are described in Section 5.1.6.

The primary land use at NWF is aviation and ground maneuver training, as described in the 2010 Final EIS (Volume 2, Chapter 8: Land and Submerged Land Use, Section 8.1, Affected Environment, pages 8-19 to 8-25). Existing land uses at the LFTRC include the Ritidian Unit of the Guam NWR located along the cliff and coastline, including USFWS facilities and associated parking.

The proposed LFTRC is north of the NWF expeditionary runways that generate APZs adjacent to the proposed LFTRC, as shown in Figure 5.5.6-1. The NWF area is used for a variety of airfield and ground training exercises. The PRTC is located southwest of the proposed LFTRC. Land use constraints in the NWF area include SDZs and ESQD arcs and water wellhead protection buffers. The Ritidian Aid to Navigation, consisting of a flashing light and a daymark mounted to a tower, is located at the cliff edge, as shown on Figure 5.5.6-1. The AAFB land use plans identify the area within the NWF LFTRC as Park/Open Space.

The DOI-controlled land is naturally-vegetated land that is used for conservation with an administrative building, an access road and parking areas. There are other land uses within the proposed LFTRC and vicinity that are addressed under Terrestrial Biological Resources, Marine Biological Resources, and Recreational Resources (Sections 5.5.8.2, 5.5.9.2 and 5.5.7.2, respectively).

The North and Central Land Use Plan designation for the DOI-controlled lands is “federal” and the private properties are designated Tourist/Resort (Figure 5.5.6-1). Access to the western private property is via Route 3A through AAFB property, under agreement with the landowners, GovGuam and DoD. The road is in poor condition. The existing development is low density with few permanent buildings. The land uses include gardening, swimming, fishing, and social gatherings.
Figure 5.5.6-1
Land Use in the Vicinity of NWF LFTRC Alternative 5

Sources: DON 2010, GBSP 2013, NAVFAC Pacific 2013
Access to the eastern 46 privately-owned parcels that abut Jinapsan Beach is through AAFB and since the events of 9/11 access has been limited. AAFB issues passes for people and vehicles accessing Jinapsan Beach. Pass holders proceed from AAFB Main Gate to Tarague Beach, where they can park their cars and continue on foot or via sand/gravel road to their property. Part of the site was formerly known as Star Sand Resort and was operated for day-use ecotourism, but AAFB support for this ended after 9/11. The access issue for private landowners at Jinapsan Beach and their families has been resolved to the satisfaction of the landowners and AAFB. AAFB rewrote base access procedures in 2009 to facilitate the ability of the affected people to enjoy their property, and a congressional appropriation was applied toward improving the roadway access to the private lands. This work was completed in 2014 and the private property users will continue to access their property through the AAFB Main Gate. There are existing military training noise (Section 5.5.4) and APZ encumbrances on the private properties bordering NWF. There are no permanent residential populations on the private lands. In addition, no off-base utilities or access roads that would require new easements are proposed.

5.5.6.2 Environmental Consequences

Land use impacts are addressed in this section. Land ownership impacts are addressed in Section 5.5.15, Socioeconomics and General Services.

Construction

As previously discussed in Chapter 3, Section 3.6.3.1, all changes in land use are considered long-term operational impacts. Therefore, there is no construction-phase analysis for this resource under any of the alternatives.

Operation

Although Air Force stakeholders have raised a number of concerns regarding potential impacts to ongoing military training activities at NWF, any potential impacts to ongoing military training activities at NWF would be resolved through the installation planning process for implementing the proposed action, and long-term land use impacts would be less than significant. For example, during preliminary facility planning for Alternative 5, the DON adjusted the range layout to unencumber the Joint Threat Emitter and thereby eliminate the need to relocate that facility. Other potential mission impacts associated with the NWF location (e.g., airspace impacts around active runways at AAFB or the expeditionary runway at NWF, and the PRTC) are the subject of ongoing discussions between Air Force, Navy, and Marine Corps planners. For example, the Commanders of Pacific Air Forces and Marine Forces Pacific have agreed to a memorandum of agreement detailing specific mitigation measures.

Although the federal government already controls the submerged land area within the SDZ footprint, the public is allowed access most of the year. The training schedule at the LFTRC would prohibit public access to federal submerged land, representing a new long-term restriction on public access. The submerged lands are valued for recreational activities and access to important fishing sites, as described in Section 5.5.7, Recreational Resources. The restricted submerged land areas would be noted on navigation maps. The public would be allowed to access the submerged lands north of NWF when the LFTRC is not in use; however, the area would be restricted when the ranges are in use. Such restrictions would be limited to the minimum SDZ area and period of use required for the LFTRC. The DoD would also consider requests for special events, on a case-by-case basis. As described in Section 3.6.3, Approach to Analysis, new access restrictions placed on non-DoD populations is a potentially significant adverse impact.
The USFWS recommended eliminating Alternative 5 during the NEPA scoping period, and one of the reasons provided was that the access restrictions could compromise the ability of USFWS to carry out critical conservation and education actions specific to the Ritidian Unit of the Guam NWR. Subsequently, Section 2822 of the FY 2015 NDAA authorizes the Secretary of the Navy and the Secretary of the Interior to enter into an agreement which would provide for the establishment and operation of an SDZ which overlays the Ritidian Unit or a portion thereof in order to accommodate operation of the LFTRC preferred alternative at NWF by the DON and the continued management of the Ritidian Unit by the USFWS. Section 2822 requires that the agreement shall include measures to maintain the purposes of the Ritidian Unit. Therefore, current conservation land uses would continue within the SDZs. There would be no significant impact on the land use.

There would be new access restrictions imposed for areas within the SDZs for safety reasons. There would be a direct and long-term impact associated with the decrease in access to the Ritidian Unit of the Guam NWR encumbered by the SDZs when the ranges are in use. The agreement negotiated under the authority of Section 2822 of the FY 2015 NDAA will address any access restrictions to the Ritidian Unit, including development of procedures to allow sufficient access to ensure management, use, and enjoyment of the Ritidian Unit consistent with its purposes.

The Ritidian Aid to Navigation (see Figure 5.5.6-1) is located within the SDZ; however, there would be no impact on its maintenance or operation.

As proposed and analyzed in this SEIS, the USFWS facilities within the Ritidian Unit and associated access roads would be relocated. No significant land use impacts would be associated with this relocation. Any decisions regarding the relocation of the USFWS facilities and/or construction to improve beach access at the Ritidian Unit of the Guam NWR are dependent upon the outcome of consultations under section 7 of the ESA and negotiation of the agreement authorized by Section 2822 of the FY 2015 NDAA.

Route 3A would continue to be used to access the proposed relocated USFWS facilities and the private property along the western coast. The proposed action would improve portions of the deteriorated Route 3A. There would be no adverse impact on access to the private lands located west of Route 3A. The portion of the access road to the existing USFWS facilities that is within the SDZ would not be accessible to the public when the ranges are in use. An existing road outside the SDZ and north of the proposed USFWS replacement facilities would be improved to provide alternate public access to Ritidian Beach (see Figure 5.5.6-1). Any decisions regarding the relocation of the USFWS facilities and/or construction to improve beach access at the Ritidian Unit of the Guam NWR are dependent upon the outcome of consultations under section 7 of the ESA and negotiation of the agreement authorized by Section 2822 of the FY 2015 NDAA.

The Zone 3 noise contour would not extend beyond federal property. Zone 2 noise contours would extend to private lands on the east, as described in the Section 5.5.4.2, Noise and shown on Figure 5.5.4-1. However, no existing or planned residential use (or other sensitive receptors like schools or medical facilities) was identified within the Zone 2 contours. There would be no significant impact to current or planned private land use east of the SDZ due to noise.

The private lands and relocated USFWS buildings to the west/southwest of NWF would be outside of the Zone 2 noise contour. The private land is designated Tourist/Resort. There would be no significant impact to current or planned land uses due to noise. Any decision regarding the relocation of the USFWS facilities is dependent upon the outcome of consultations under section 7 of the ESA and negotiation of the agreement authorized by Section 2822 of the FY 2015 NDAA.
Significant mitigable impacts were identified for Alternatives 1, 2, 4 and 5. Alternative 5 would have a greater impact to land use resources than Alternative 3, which would have no impact.

5.5.7 Recreational Resources

5.5.7.1 Affected Environment

A list of recreational resources at NWF is contained in the 2010 Final EIS (Volume 2, Chapter 9: Recreational Resources, Section 9.1.2.1: Andersen AFB, pages 9-1 to 9-3). Comprehensive descriptions of recreational resources near NWF are contained in the 2010 Final EIS (Volume 9, Appendix G, Chapter 1: Recreational Resources, Section 1.2.1: Andersen AFB and Section 1.2.3: Non-DoD Lands, pages G-1-1 to G-1-5). Table 5.5.7-1 identifies the recreational resources near Alternative 5.

For this SEIS, the uses and geographical areas of proposed development at AAFB are modified from the above-referenced section of the 2010 Final EIS. As described in Chapter 2 of this SEIS, Alternative 5 proposes using the NWF area of AAFB as a LFTRC. Figure 2.5-6 shows the SDZ for each individual range in the proposed LFTRC. The SDZs would extend over ocean and shoreline recreational resources in a northern direction.

As described in the 2009 Guam NWR Comprehensive Conservation Plan, the Ritidian Unit of the Guam NWR provides recreational opportunities in the form of a nature center, wildlife observation, cave and forest tours, limited boat fishing, cultural resource interpretation, and environmental education. Public recreational activities are permitted on approximately 120 acres (48 ha) west of the USFWS facilities. Additionally, the public may picnic, swim, snorkel, scuba dive, and hike in open portions of the Ritidian Unit.

Since 2003, over 18,000 people have visited the refuge for recreational fishing. Offshore fishing areas in the vicinity include Rota Banks, 45 Bank, Ritidian Point. Additionally, there are Fish Aggregating Devices located north of Ritidian Point (see Figure 3.6.1-1). The SDZ area that extends over the water at Ritidian Point is typically fished during the season when seas are calm enough for small boats, with the majority of fishing occurring during the summer months. Of the recorded fishing trips, approximately 65% occur on the weekends (GDAWR 2014).

The Ritidian Unit and associated Nature Center provide environmental education programs to Guam’s students. Between 1998 and 2012, nearly 97,000 elementary and middle school students visited the refuge on school field trips. Since 2003, over 53,000 high school and college students have visited the refuge on school field trips or for volunteer activities. The Nature Center is open 7 days a week, from 8:30 a.m. to 4:00 p.m., and the admission is free. It is estimated that approximately 20 people visit the nature center daily (USFWS 2009). Within the Ritidian Unit, there are 17 parking areas and up to 18 picnic sites for day visitors to the public facilities.

5.5.7.2 Environmental Consequences

Construction

Under Alternative 5, the Guam NWR Nature Center at Ritidian Point would be replaced at a location outside the SDZs prior to operation of the LFTRC, as shown in Figure 2.5-6. The existing center would be utilized until the new center becomes operational. This would ensure uninterrupted visitor use of the center during the construction period, and yield no direct or indirect adverse impacts to recreational resources. Any decision regarding the relocation of the USFWS facilities is dependent upon the outcome of consultations under section 7 of the ESA and negotiation of the agreement authorized by Section 2822 of the FY 2015 NDAA. However, construction-related vehicles travelling along Route 3A would potentially cause a less than significant adverse impact due to traffic congestion and delays to persons attempting to gain access to the Ritidian Unit.
Operation

Proposed activities near NWF assessed in the 2010 Final EIS were limited to land-based training and operation of various aircraft at NWF. Public access is currently permitted to the Ritidian Unit of the Guam NWR and to the associated Ritidian Beach, as well as the private beach dwellings at Urunao Beach. The area to the east of the USFWS facilities is currently closed to the public. Access is also currently limited on the northern portion of the beach due to sea turtle nesting. The SDZs would extend over a portion of the Guam NWR, including onshore and offshore areas. Access to these areas could be restricted during operation of the LFTRC depending upon which ranges and which caliber of weapons are in use at any given time. The agreement negotiated under the authority of Section 2822 of the FY 2015 NDAA would address any access restrictions, including development of procedures to allow sufficient access to ensure management, use, and enjoyment of the Ritidian Unit consistent with its purposes.

Implementation of Alternative 5 would result in direct impacts to recreational resources in the area when ranges are in use. Among the ranges within the LFTRC, the MPMG Range has the largest SDZ and is the only SDZ that would preclude access to a portion of the publicly accessible areas of the Ritidian Unit of the Guam NWR. When any combination of the other ranges not including the MPMG Range are in use, their SDZs would not restrict access to the publicly accessible portion of the Ritidian Unit. Access within the MPMG Range SDZ would be restricted during MPMG Range operational periods. Recreational resources within the MPMG range SDZ include a portion of existing hiking trails leading to caves containing unique ancient Chamorro paintings. The trails and caves that would fall within the MPMG Range SDZ are currently open for access during normal Refuge hours. Impacts of loss of access to the portion of the Ritidian Unit trails, caves and other cultural resources that would fall within the MPMG Range SDZ while it is operational would be significant.

An existing road outside the SDZ and north of the proposed relocation of the USFWS facilities would be improved to provide alternate public access to Ritidian Beach to minimize the impact of access restrictions when the MPMG Range is in use. Areas that would be accessible via the new access route include portions of the existing beach road, beach, cultural features, and trails located outside the MPMG Range SDZ. Two caves would remain outside the MPMG range SDZ and would continue to be accessible via the new access route. MPMG range operations would typically occur during weekdays, which would minimize impacts. Any decision regarding the relocation of the USFWS facilities and/or construction to improve beach access at the Ritidian Unit of the Guam NWR are dependent upon the outcome of consultations under section 7 of the ESA and negotiation of the agreement authorized by Section 2822 of the FY 2015 NDAA.

Although the Alternative 5 LFTRC SDZs would not encompass Rota Bank or Fish Aggregating Devices as shown on Figure 3.6.1-1, there would be loss of access to areas relevant to recreational boaters and fishermen. Offshore fishing areas located within the LFTRC SDZs would be inaccessible during associated range use. When the associated range is in use, boaters would need to either transit around the active SDZs or coordinate with range control to determine when it is safe to transit through the SDZs.

Recreational boating and fishing would be permitted within the SDZs when live-fire training is not being conducted at the range.

As stated in Section 5.5.7.1, approximately 65% of fishing trips occur on the weekends and 35% of fishing trips occur on weekdays. As stated in Section 2.2.3, training at the LFTRC would typically occur on weekdays, but periodic weekend use could occur as needed. To provide awareness of times that the range is in use, the DON would provide the proposed training schedule to the U.S. Coast Guard, who would issue and broadcast a Notice to Mariners that would identify the location of the SDZs and direct
vessel operators to navigate clear of the active SDZs. Additionally, boaters and fishermen would be able to contact range control via radio or phone to get real time updates of active ranges, which would minimize impacts. This communication would allow boaters to transit SDZs during scheduled training days when the ranges are temporarily inactive. Range lookouts would scan the SDZs prior to and during live-fire training to ensure that there are no vessels within or approaching the SDZs. If vessels are at risk of entering an SDZ, use of the range would be suspended until the vessel leaves the SDZ area. Based on the considerations described above, Alternative 5 would result in less than significant impacts to recreational boating and fishing during operation.

As shown in Figure 5.5.4-1, noise impacts above 65 ADNL (the level at which noise is considered incompatible with noise-sensitive land uses) are almost entirely within the SDZ. Since the SDZ is closed to the public during training events (i.e., noise-producing events), there would be no impact to people seeking recreation. The new USFWS Nature Center would be located outside of the SDZ. Noise during training events would be between 55 and 64 ADNL at the relocated Nature Center and nearby beach. This noise level is considered compatible with most land uses; however, the additional noise could lessen visitor enjoyment. Because noise levels would be compatible with the recreational land use, noise impacts to recreational resources would be less than significant.

5.5.8 Terrestrial Biological Resources

5.5.8.1 Affected Environment

Vegetation Communities

Figure 5.5.8-1 depicts the vegetation communities associated with the NWF LFTRC. The vegetation communities were mapped based on the following sources:

- AAFB (2008a) - base-wide mapping.
- Field surveys conducted in 2012 (NAVFAC Pacific 2013a).
- 2011 aerial imagery - review of that imagery showed some recently developed land.

Vegetation types are described in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.1.1: pages 10-1 to 10-6). Portions of the NWF area were evaluated during surveys in 2012 (NAVFAC Pacific 2013b) to determine if there had been any changes to vegetation communities since the AAFB (2008a) basewide mapping effort. Based on the 2012 surveys, vegetation mapping has been revised to account for several areas that have been cleared since the 2008 mapping. No other changes were made to the 2008 mapping within the impacted areas shown in Figure 5.5.8-1.

The majority of the area that would be potentially impacted under Alternative 5 is primary and secondary limestone forest (Figure 5.5.8-1). The north end of the proposed MPMG Range from approximately the footprint of the range to the northern limits of the impacted area consists of highly weathered, rugged karst limestone terrain characterized by sharp pinnacles and towers and deep, narrow fissures that support a primary limestone vegetation community. Primary limestone forest in this area is generally less disturbed by ungulates, particularly feral pigs.

Terrestrial Conservation Areas

All of the area associated with construction of the ranges under Alternative 5 is within established Overlay Refuge (Figure 5.5.8-2). Additional information on Overlay Refuge lands is provided in Section 3.8.1.2 of this SEIS and the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.1.3: Special-Status Species, pages 10-8 to 10-9). Immediately north of AAFB is the Ritidian Unit of the Guam NWR. See Section 5.5.6, Land and Submerged Land Use for a detailed discussion of the NWR. In addition, the terrestrial portion of the Ritidian Unit of the Guam NWR is also designated critical habitat, which is discussed below under Special-Status Species: Federal ESA-Listed and Proposed Species and Designated Critical Habitat.

Several areas have been created on AAFB for scientific research or as conservation measures for previous environmental impacts and as required in USFWS BOs issued under the ESA. In accordance with a BO for previous Air Force actions on AAFB (USFWS 2006b), an ungulate exclosure has been constructed within the proposed LFTRC (Figure 5.5.8-2).

Wildlife - Native Species

During detailed surveys of migratory birds within open habitats on AAFB in 2011, 997 individuals of 9 species were observed (NAVFAC Marianas 2013). Six species were identified in short-grass habitat with Pacific golden plover being the most commonly observed followed by the ruddy turnstone. Other species observed included wood sandpiper, wandering tattler, gray-tailed tattler, sharp-tailed sandpiper, Pacific reef heron, whimbrel, and ruff. Surveys for forest birds in 2012 at four locations in the proposed NWF LFTRC area did not detect any native birds (NAVFAC Pacific 2013b). Other native species observed on AAFB in past studies, as described in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.3.1: page 10-22), include yellow bittern, fairy tern, barn swallow, and fork-tailed swift (NAVFAC Pacific 2010).

Non-listed native reptiles observed at AAFB in the NWF area include the blue-tailed skink and mutilating gecko (NAVFAC Pacific 2010). The 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.3.1: Andersen AFB, page 10-22) also lists and provides information about other native wildlife species present on AAFB including the coconut crab and butterflies. Several coconut crabs were observed during 2012 surveys in the NWF area (NAVFAC Pacific 2013b).

Non-native species of birds, mammals, reptiles, amphibians, and invertebrates present at AAFB, including the NWF area, are described in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.3.1: Andersen AFB, pages 10-23 to 10-24).

Special-Status Species: Federal ESA-Listed and Proposed Species and Designated Critical Habitat

Four ESA-listed (Mariana fruit bat, green and hawksbill turtles, Serianthes nelsonii) and four proposed species (Mariana eight-spot butterfly, Tabernaemontana rotensis, Bulbophyllum guamense, and Psychotria malaspinae) occur on AAFB within the Alternative 5 action area (Table 5.5.8-1 and Figure 5.5.8-3). Although “suitable habitat” for special-status species is present within the Alternative 5 project areas, the brown treesnake, the primary factor in the extirpation of special-status wildlife species on Guam and one of the largest obstacles to achieving recovery of special-status species, is still considered abundant and widespread on Guam. Until brown treesnakes are suppressed or removed from at least targeted areas on Guam, the habitat is not in a suitable condition to support the survival of special-status species due to current snake abundance on Guam (e.g., Guam Micronesian kingfisher, Guam rail, Mariana crow) (USFWS 2010a).

In addition to the discussion below, additional information for individual species at AAFB NWF was provided in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.1.3.1: Andersen AFB, pages 10-24 to 10-33).

**MARIANA FRUIT BAT.** Recent fruit bat observations on AAFB were of flying and (in a few cases) roosting individuals and were most commonly observed in three general regions on AAFB: the cliffline extending from above the CATM Range east to Pati Point; in or near the MSA; and in the vicinity of the HMU (see Figure 4.1.8-5) (JRM et al. 2012a). There have been only three fruit bat observations within the Alternative 5 action area on AAFB since 2005 (Janeke 2006b as cited in AAFB 2008b; JRM et al. 2012b, 2012c, 2012d). From 2010 through November 2013, there have been five reports of one to three fruit bats in flight at the Ritidian Unit of the Guam NWR. Guam NWR personnel believe that fruit bats may roost near Star Cave at Ritidian Point on NWR property (Personal communication via email from Jennifer Cruce, Guam NWR to Anne Brooke, JRM, November 7, 2013). High and medium priority fruit bat roosting habitat as defined in the AAFB Mariana Fruit Bat Management Plan (AAFB 2008b) are found within the action area (see Figure 5.5.8-3). These areas were identified based on historical colony roost locations and current habitat conditions on AAFB.

Fruit bat recovery habitat was described by the USFWS in the BO for the Guam and CNMI Military Relocation (USFWS 2010a) and includes the following vegetation types (based on vegetation mapping by the USFS [2006]) for foraging, roosting, and breeding: limestone forest, coconut plantation, ravine forest, and groves of *Casuarina equisetifolia*. Fruit bat recovery habitat is found within proposed project impacted areas associated with Alternative 5 (see Figure 3.8.3-1).

Mariana Fruit Bat Critical Habitat. Immediately north of the proposed NWF LFTRC below the cliffline is the Ritidian Unit of the Guam NWR (see Figure 5.5.8-3). In 2004, the USFWS designated the 370.6-acre (150-ha) terrestrial portion of the Ritidian Unit of the Guam NWR as critical habitat for the Mariana fruit bat (USFWS 2004a, 2014c). In accordance with the ESA, the designation of critical habitat is based on those physical and biological features that are essential to the conservation of the species and that may require special management considerations or protection. Such features are termed primary constituent elements (PCEs) and are those features required by the species for the biological needs of foraging, sheltering, roosting, and rearing of young. The PCEs for the fruit bat are:

- Plant species used for foraging, such as breadfruit, papaya, fadang, fig, kafu, coconut palm, and talisai.
- Remote locations, often within 328 feet (100 m) of clifflines that are 260 - 590 feet (80 - 180 m) tall, with limited exposure to human disturbance and that contain mature fig, chopak, gago, macadamia nut tree, panao, fagot, and other tree species that are used for roosting and reproductive activity (USFWS 2004a).

These PCEs of Mariana fruit bat critical habitat are found in areas supporting primary limestone, secondary limestone, ravine, swamp, coconut palm, and coastal forests composed of native and introduced plant species (USFWS 2004a).

MARIANA SWIFTLET. A nest/roost cave previously used by Mariana swiftlets is known from Ritidian Point, but this cave was abandoned by the late 1970s (USFWS 1991). Biological surveys conducted in 2008 and 2009 in support of the 2010 Final EIS and in 2012 and 2013 in support of this SEIS, did not record any incidental observations of Mariana swiftlets (NAVFAC Pacific 2010, 2013b; UoG 2014). The only known occupied nest/roost caves on Guam are located on the NAVMAG more than 20 miles (32 km) south of the NWF LFTRC action area. As swiftlets forage within 0.6-1.2 miles (1-2 km) of their nest/roost caves (Jenkins 1983), it unlikely that individuals from the only known population on Guam over 20 miles (32 km) away would occur within the NWF LFTRC action area. Therefore, as the Mariana swiftlet is not found within the impacted areas of Alternative 5, this species is not addressed further.

MARIANA CROW. Since 2009, the population of Mariana crows on Guam consisted only of two males on AAFB, occurring primarily within the MSA (USFWS 2009c). However, as of 2012, the Mariana crow is considered extirpated in the wild on Guam (Personal communication via letter from USFWS, Pacific Islands Fish and Wildlife Office, Honolulu, HI regarding the DON NOI for Proposed Placement of
Guam and CNMI Military Relocation
(2012 Roadmap Adjustments) SEIS

Final

July 2015

LFTRC on Guam NWR; December 7, 2012). The closest population of crows is on the island of Rota, approximately 56 miles (90 km) north of Guam. Crows in northern Guam used primary limestone forest for nesting, with nests exclusively in native trees. They have been observed foraging in both primary and secondary limestone forests and tangantangan (USFWS 2005). Crow recovery habitat is found within proposed project impacted areas on Finegayan and in support areas on AAFB and adjacent lands (see Figure 3.8.3-1).

Mariana Crow Critical Habitat. In 2004, the USFWS designated 362.8 acres (146.8 ha) terrestrial portion of the Ritidian Unit of the Guam NWR as critical habitat for the Mariana crow (see Figure 5.5.8-2) (USFWS 2004a, 2014c). The PCEs required by the crow for the biological needs of foraging, sheltering, roosting, and rearing of young are:

- Emergent and subcanopy trees with dense cover for breeding such as fagot, pengua, ifit, ahgao, aabang, fig, yoga, and faia.
- Sufficient area of predominantly native limestone forest to allow nesting at least 950 feet (290 m) from the nearest road and 203 feet (62 m) from the nearest forest edge and to support Mariana crow breeding territories (approximately 30-91 acres [12-37 ha]) and foraging areas for nonbreeding juvenile crows.
- Standing dead trees and plant species for foraging, such as mapunao, breadfruit, coconut palm, fagot, pago, ifit, tangantangan, langiti, kafu, ahgao, fig, and yoga (USFWS 2004a).

These PCEs of Mariana crow critical habitat are found in areas supporting limestone, secondary, ravine, swamp, agricultural, and coastal forests composed of native and introduced plant species (USFWS 2004a).

GUAM MICRONESIAN KINGFISHER. The Guam Micronesian kingfisher was extirpated in the wild by 1988 and is now found only in captivity on Guam and at mainland zoos. Kingfishers utilized a wide variety of habitats including primary and secondary limestone forest, strand forest, coconut forest, edge habitats, and forest openings, but mature forests with tree cavities suitable for nesting may be an important requirement for kingfisher reproduction (USFWS 2008b). Kingfisher recovery habitat within the proposed impacted areas of Alternative 5 includes primary and secondary limestone forest, coconut forest, and tangantangan (see Figure 3.8.3-1).

Guam Micronesian Kingfisher Critical Habitat. In 2004, the USFWS designated 362.8 acres (146.8 ha) of the Guam NWR – Ritidian Unit as critical habitat for the Guam Micronesian kingfisher (see Figure 5.5.8-2) (USFWS 2004a, 2014c). The PCEs required by the kingfisher for the biological needs of foraging, sheltering, roosting, and rearing of young are:

- Closed canopy and well-developed understory vegetation; large (minimum of approximately 17 inches [43 cm] diameter at breast height), standing dead trees (especially fanio, umumu, breadfruit, fig, and coconut palm); mud nests of *Nasutitermes* spp. termites; and root masses of epiphytic ferns for breeding.
- Sufficiently diverse structure to provide exposed perches and ground surfaces, leaf litter, and other substrates that support a wide range of vertebrate and invertebrate prey species for foraging kingfishers.
- Sufficient overall breeding and foraging area to support kingfisher territories of approximately 25 acres (10 ha) each (USFWS 2004a).
These PCEs of Guam Micronesian kingfisher critical habitat are found in areas supporting limestone, secondary, ravine, swamp, agricultural, and coastal forests composed of native and introduced plant species (USFWS 2004a).

GUAM RAIL. The Guam rail has been extirpated in the wild on Guam since 1985 and exists primarily in captivity on Guam and in mainland zoos. Experimental populations of Guam rails were introduced onto Rota, CNMI in 1989 and onto Cocos Island, off the southern coast of Guam, in 2011 (USFWS 2009b; BirdLife International 2013). The Guam rail prefers edge habitats, especially grassy or secondary vegetation areas which provide good cover; mature forest is deemed only marginal for the Guam rail (USFWS 2009b). Rail recovery habitat within the impacted areas of Alternative 5 includes secondary limestone forest, herbaceous scrub, coconut forest, and tangantangan (see Figure 3.8.3-2).

SEA TURTLES. Green sea turtle nesting is documented on the Ritidian Unit of the Guam NWR to the north of the proposed impacted areas. The hawksbill sea turtle has not been definitively determined to nest on Guam (JRM 2013). There are no sea turtle nesting beaches within the proposed impacted areas associated with Alternative 5.

SLEVIN’S SKINK. Originally found on Guam, Cocos Island, Rota, Tinian, Guguan, Alamagan, Asuncion, and Maug, it is now limited to Cocos Island, Sarigan, Guguan, Alamagan, Pagan, and Asuncion. Slevin’s skink has not been recorded on Guam since 1945 and is believed to be extirpated from Guam; it is now known to occur only on Cocos Island (an atoll south of Guam) (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 5 (USFWS 2014b). Therefore, as Slevin’s skink is not found within the impacted areas of Alternative 5, this species is not addressed further.

MARIANA EIGHT-SPOT BUTTERFLY. Surveys conducted in 2012 and 2013 within the Alternative 5 action area have observed eight-spot butterfly adults, eggs, and chrysalis (NAVFAC Marianas 2013; NAVFAC Pacific 2013b; UoG 2014) (see Figure 5.5.8-3). In addition to these observations, extensive host plant patches and five occurrences with adult or larval butterflies were documented during 2012 project-specific surveys in the NWF area (see Figure 5.5.8-3) (NAVFAC Pacific 2013b). All adult and larva observations were near the cliffline in the area of the proposed MPMG Range; host plant patches were present in this area and were also found in other locations.

MARIANA WANDERING BUTTERFLY. The Mariana wandering butterfly has not been seen on Guam since 1979 and considered extirpated; a single remaining population occurs on Rota, CNMI (USFWS 2013). The only species known to be a Mariana wandering butterfly host plant (Maytenus thompsonii) is a common shrub of limestone forests on Guam and has been observed within the impacted areas of Alternative 5 (see Figure 5.5.8-3) (Moore and McMakin 2001; UoG 2014).

TREE SNAILS. In surveys conducted in 2011 and 2013, no tree snails were observed in the NWF area (NAVFAC Marianas 2013; UoG 2014). Although tree snails were not found within the impacted areas of Alternative 5, potential tree snail habitat does occur within the impacted areas of Alternative 5.

SERIANTHES TREE. This is a large tree reaching 60 feet (18 m) or more in height, with an average trunk diameter of nearly 6 feet (2 m). It grows along limestone cliffs, usually in primary forest, but Fosberg (1960) reported that it also occurred in low numbers in late successional secondary limestone forest. There is only one remaining mature seed-bearing tree on Guam and it is in the NWF area above Ritidian Point within primary limestone forest (see Figure 5.5.8-3). Two planted Serianthes saplings are located in the Tarague Basin area approximately 4 miles (6.4 km) east of the lands considered under this alternative. There were no additional observations of this species during 2012 surveys of the Alternative 5 action area.
Serianthes recovery habitat does occur within the impacted areas of AAFB (see Figure 3.8.3-2).

Heritiera longipetiolata. This endemic tree is found on AAFB in crevices of rough limestone in primary limestone forest. A 2007 base-wide survey documented the species as occurring at numerous locations on AAFB, primarily in the central portion of the base, and near the limestone cliffs in the northeast and southeast corners (UoG 2007) (see Figure 4.1.8-5). In addition, no H. longipetiolata were observed during surveys of the action area in 2010, 2012, and 2013 (NAVFAC Pacific 2010, 2013b; UoG 2014). There are no records of the species within the impacted areas of AAFB (USFWS 2014b). Therefore, as H. longipetiolata is not found within the impacted areas of Alternative 5, this species is not addressed further.

Tabernaemontana rotensis. The distribution of this species was evaluated on AAFB in 2007 (UoG 2007). Over 21,000 T. rotensis individuals were found throughout AAFB at 265 mapped locations, primarily in the central portion of the base and near the limestone cliffs in the northeast (see Figure 4.1.8-2). In addition, no T. rotensis were observed during surveys of the action area in 2010, 2012, and 2013 (AAFB 2008a; NAVFAC Pacific 2010, 2013b; UoG 2007, 2014). There are no records of the species within the impacted areas of AAFB (USFWS 2014b). Therefore, as T. rotensis is not found within the impacted areas of Alternative 5, this species is not addressed further.

Cycas micronesica. This species is abundant in many areas on AAFB, particularly in primary limestone forest habitat. Recent surveys within the Alternative 5 action area found numerous individuals that were in fair or poor condition due to the Asian cycad scale (NAVFAC Pacific 2013b; UoG 2014). There are no records of the species within the impacted areas of AAFB (USFWS 2014b). Therefore, as C. micronesica is not found within the impacted areas of Alternative 5, this species is not addressed further.

Bulbophyllum guamense. An epiphyte in the orchid family, this species occurs in mat-like formations on tree branches of coastal lowland/limestone forests. Currently, there are 8 known occurrences on Guam totaling fewer than 250 individuals. There is 1 occurrence within the northern edge of impacted area of Alternative 5 along the cliffline (Figure 5.5.8-3) (USFWS 2014a, 2014b).

Eugenia bryanii. A perennial shrub in the myrtle family, the species is known only from the island of Guam. Historically, E. bryanii is known from windy exposed coastal cliffs and along the Pigua River, in lowland/limestone forests. Currently, E. bryanii is known from 6 occurrences totaling fewer than 420 individuals (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 5 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as E. bryanii is not found within the impacted areas of Alternative 5, this species is not addressed further.

Maesa Walkeri. A shrub or small tree in the primrose family typically found in limestone forests, this species is known from only 2 individuals on Guam (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 5 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as M. walkeri is not found within the impacted areas of Alternative 5, this species is not addressed further.

Nervilia jacksoniae. A small herb in the orchid family, this species is found in lowland/limestone forests. On Guam, N. jacksoniae is known from 2 occurrences totaling fewer than 200 individuals (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 5 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as N. jacksoniae is not found within the impacted areas of Alternative 5, this species is not addressed further.
**PSYCHOTRIA MALASPINAE.** A shrub or small tree in the coffee family, this species is found in lowland/limestone forests. Currently, *P. malaspiniae* is known from 3 occurrences: 1 individual at Ritidian Point within the Guam NWR, 1 individual at Pågat Point, one individual at the base of Mt. Almagosa, and 2 individuals at NWF (USFWS 2014a, 2014b). None of these individuals have been observed within the last 5 years. A specimen collected from Ritidian Point in August 2013 is currently pending identification (USFWS 2014a). There is one record of an individual within the impacted area of Alternative 5 (Figure 5.5.8-3) (USFWS 2014b).

**SOLANUM GUAMENSE.** A small shrub in the nightshade family that occurs within limestone forests. Currently, *S. guamense* is known from a single occurrence of 1 individual on Guam (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 5 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *S. guamense* is not found within the impacted areas of Alternative 5, this species is not addressed further.

**TINOSPORA HOMOSEPALA.** A vine in the moonseed family found in limestone forests. Currently, *T. homosepala* is known from 3 occurrences totaling approximately 300 individuals (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 5 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *T. homosepala* is not found within the impacted areas of Alternative 5, this species is not addressed further.

**TUBEROLOBIUM GUAMENSE.** An epiphyte in the orchid family found in limestone forests. Currently, *T. guamense* is known from 3 occurrences on Guam: 2 occurrences within the NAVMAG and one occurrence within Finegayan (NAVFAC Pacific 2010; USFWS 2014a, 2014b). There are no records of the species within the impacted areas of Alternative 5 (NAVFAC Pacific 2010, 2013a, 2013b; USFWS 2014a, 2014b). Therefore, as *T. guamense* is not found within the impacted areas of Alternative 5, this species is not addressed further.

**DENDROBIUM GUAMENSE.** An epiphyte in the orchid family, the species occurs within lowland/limestone forests and savanna. On Guam, there are 4 occurrences totaling fewer than 250 individuals (USFWS 2014a). There are no records of the species within the impacted areas of Alternative 5 (USFWS 2014b). Therefore, as *D. guamense* is not found within the impacted areas of Alternative 5, this species is not addressed further.

**Special-Status Species: Guam-Listed Species and SOGCN**

Two Guam-listed endangered species (Micronesian starling white-throated ground dove) occur on AAFB within the Alternative 5 action area (see Table 5.5.8-1). Species that are both Guam-listed and federally listed were discussed above.

**MICRONESIAN STARLING.** As described in Section 4.3.8.1, the starling is present in the housing area at AAFB (JRM 2013; J. Savidge, Colorado State University, personal communication to G. Metzler, Cardno TEC, May 23, 2013) and has also been observed occasionally throughout AAFB, primarily east of the MSA (NAVFAC Pacific 2010; JRM et al. 2012d; JRM 2013) (see Figure 4.1.8-5). The starling has not been observed at NWF or the impacted areas during numerous past and recent surveys conducted within the area (NAVFAC Pacific 2010, 2013b; JRM et al. 2012b, 2012c, 2012d; JRM 2013). On Guam, it is also present on Cocos Island, parts of Hagåtña, and the southeastern beach strand areas (JRM 2013). Even though the Micronesian starling has not been recently documented within the impacted areas of the Alternative 5, sightings of this species elsewhere on AAFB suggest habitat utilization may potentially occur within NWF action area.
WHITE-THROATED GROUND DOVE. Although the white-throated ground dove is considered extirpated from Guam due to the brown treesnake (GDAWR 2006), it is seen on very rare occasions on AAFB, primarily within the MSA and the southeastern corner of the base (JRM et al. 2012a, 2012b; NAVFAC Marianas 2013; UoG 2014). Observed individuals are thought to be transients from Rota (GDAWR 2006; NAVFAC Marianas 2013) and a resident or breeding population does not occur on Guam. The white-throated ground dove was not seen or heard during surveys of the action area in 2009, 2012, and 2013 (NAVFAC Pacific 2010, 2013a, 2013b; UoG 2014). Therefore, as the white-throated ground dove is not found within the impacted areas of Alternative 5, this species are not addressed further.

MOTH SKINK AND PACIFIC SLENDER-TOED GECKO. The moth skink and Pacific slender-toed gecko are listed by Guam as endangered. These species are threatened primarily by introduced species (e.g., feral ungulates, curious skinks, musk shrews, rats, brown treesnakes, and feral cats) and loss of limestone forest habitat. Although both species have been observed within AAFB, neither were observed during 2009 and 2012 surveys of the Alternative 5 action area (NAVFAC Pacific 2010, 2013b).

5.5.8.2 Environmental Consequences

Construction

Vegetation. Impacts to vegetation from the construction of the HG Range at Andersen South were discussed in Section 5.1.8.2 and there would be less than significant impacts. The following analysis focuses on the proposed range facilities at NWF.

Under Alternative 5, 89 acres (36 ha) of primary limestone forest and 111 acres (45 ha) of secondary limestone forest would be impacted during proposed construction activities at NWF (Table 5.5.8-2 and see Figure 5.5.8-1). In addition, 63 acres (26 ha) of currently developed areas would be impacted as well as 53 acres (20 ha) of herbaceous scrub/grassland and coconut plantation that are of less importance as habitat for most wildlife and special-status species.

Legend: PLF = primary limestone forest; SLF = secondary limestone forest; HS = herbaceous scrub; CP = coconut plantation; Dev = developed.

Native limestone forest, both primary and secondary, has been significantly reduced on Guam due to past and ongoing actions including extensive disturbance during and after WWII, widespread planting of non-native species; and impacts from non-native ungulates; development; fire; and deforestation. As stated in Section 3.8.1.1, limestone forests on Guam are important since they retain the functional ecological components of native forest that provide important habitat for the majority of Guam’s native species, including ESA-listed, ESA-proposed, and Guam-listed species and Guam SOGCN, as well as maintaining water quality and reducing fire risk. Non-native forest communities (e.g., tangantangan, Vitex) significantly alter the forest structure, composition, and resilience to other disturbance processes and do not provide the conditions suitable for native flora and fauna species to persist (Morton et al. 2000; GDAWR 2006; Guam Department of Agriculture 2010; JRM 2013).
Of the 18,538 acres (7,502 ha) of primary and secondary limestone forest found on Guam, approximately 13,110 acres (5,305 ha) are found primarily within AAFB, Finegayan, and the NAVMAG (USFS 2006). Under Alternative 5, 89 acres (37 ha) of primary limestone forest and 111 (45 ha) of secondary limestone forest would be removed at NWF (see Table 5.5.8-2). Therefore, given the importance of primary and secondary limestone forest habitat for native species and the continuing loss of native limestone forest across Guam, the conversion of 200 acres (82 ha) of limestone forest to developed area would be a significant but mitigable impact to the regional vegetation community and its function.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct, long-term impacts of proposed construction activities on vegetation communities with implementation of LFTRC Alternative 5. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the contractor education program.
- **Onsite Vegetation Waste Management Procedures.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of the vegetation waste management procedures.
- **DON Guam Landscaping Guidelines.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of landscaping guidelines.
- **LFTRC Range Berm Controls.** To manage stormwater runoff and control erosion, LFTRC range berms would contain native or non-invasive herbaceous vegetation and other engineering controls.
- **Contractor Plans and Specifications.** All construction would occur within the limits of construction shown in the project figures.

**Potential Mitigation Measures**

To mitigate for significant impacts to limestone forest, the DON proposes to implement forest enhancement on a minimum of 200 acres (82 ha) of limestone forest. Forest enhancement would include but is not limited to the following actions:

- Ungulate management consisting of exclusion fencing and active control (i.e. trapping, snaring, shooting) with the goal of eradication within the fenced areas.
- Non-native, invasive vegetation removal.
- Propagation, planting, and establishment of native species that are characteristic of native limestone forest habitats (e.g., A. mariannensis, G. mariannae, F. prolixa, M. citrifolia, W. elliptica).

The degradation and loss of primary limestone and other forest habitats resulting from ungulate damage and invasion by alien plant species has substantially diminished the extent of habitat for native species in the Mariana archipelago. The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including special-status species. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).
Terrestrial Conservation Areas. Impacts from the construction of the HG Range at Andersen South were discussed in Section 5.1.8.2. As Andersen South does not contain any terrestrial conservation areas, there would be no impacts.

All of the area associated with construction of the ranges under Alternative 5 is within Overlay Refuge (see Figure 4.1.8-3). Overlay Refuge lands were established for the purpose of conserving and protecting ESA-listed species and other native flora and fauna, maintaining native ecosystems, and the conserving native biological diversity, recognizing that the primary purpose of lands within the Overlay Refuge is to support the national defense missions of the Navy and Air Force.

Approximately 298 acres (121 ha) of Overlay Refuge lands (Table 5.5.8-3), or 1.4% of the total Overlay Refuge lands on Guam, would be directly impacted under Alternative 5. This area overlaps with the vegetation communities discussed previously. The majority (188 acres [76 ha]) is comprised of limestone forest (Table 5.5.8-3). Therefore, because proposed construction activities would convert 298 acres (121 ha) of Overlay Refuge lands to developed areas, this would be a significant loss to the conservation function of these lands and implementation of Alternative 5 would result in significant but mitigable impacts to terrestrial conservation areas.

Table 5.5.8-3. Impacts to Overlay Refuge with Implementation of LFTRC Alternative 5

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct, long-term impacts of proposed construction activities on terrestrial conservation areas with implementation of Alternative 5. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

Best Management Practices

The same BMPs discussed above under Vegetation would be implemented for terrestrial conservation areas.

Potential Mitigation Measures

To mitigate for significant impacts to terrestrial conservation areas, the DON would submit a proposal to CNO Energy and Environmental Readiness Division to designate an ERA on the NAVMAG to conserve native limestone forest in southern Guam which provides habitat for special-status species. The DON has defined an ERA as a physical area or biological unit in which current natural conditions are maintained insofar as possible. These conditions are ordinarily achieved by allowing natural, physical, and biological processes to prevail without human intervention. However, under unusual circumstances, deliberate manipulation (e.g., removal or control of invasive species) may be utilized to maintain the unique feature that the ERA was established to protect (NAVFAC 1996). The proposed NAVMAG ERA would encompass approximately 553 acres (234 ha). Although the proposed NAVMAG ERA is currently part of the Overlay Refuge, implementation of these potential mitigation measures would provide an increased level of protection by further ensuring this area is maintained in
natural and near natural conditions and to have available such areas for research and scientific manipulation (NAVFAC 1996; NAVFAC Marianas 2010).

In addition, the DON proposes to submit a proposal to CNO Energy and Environmental Readiness Division to expand the existing Orote ERA by approximately 32 acres (13 ha) of terrestrial habitat. The Final Orote ERA Expansion proposal was completed FY 2013 and will be submitted for approval in 2014.

**Wildlife - Native Species.** Short-term construction noise may temporarily impact suitable habitat for native birds in the vicinity of the construction areas, but they would relocate to other areas of suitable habitat in the vicinity, and could return to the area following construction. Non-listed native reptiles are abundant throughout Guam and impacts to vegetation communities under Alternative 5 would result in less than significant impacts to non-listed native reptile populations. Implementation of Alternative 5 would not have a significant adverse effect on a population of any migratory bird species or other native wildlife species. Impacts to wildlife from the construction of the HG Range at Andersen South were discussed in Section 5.1.8.2 and impacts would be less than significant.

Therefore, as presented above, long-term, direct impacts to populations of native wildlife species would not result because these species are abundant in surrounding areas and could repopulate portions of suitable habitat within the affected area after construction. Therefore, direct impacts to native wildlife species would be less than significant with implementation of proposed construction activities associated with Alternative 5.

Proposed construction activities and associated movement of materials onto and off of Guam could increase the potential for the spread of existing or introduction of new non-native invasive species. To prevent the inadvertent spread of non-native species on Guam or to other locations off of Guam, the DON would implement standard biosecurity measures (e.g., HACCP, brown treesnake interdiction measures, coconut rhinoceros beetle vegetation management procedures, and outreach/education) into construction protocols, procedures, and activities.

The following BMPs would be implemented to avoid and minimize potential direct, long-term impacts of proposed construction activities on native wildlife with implementation of Alternative 5.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

With implementation of these BMPs, including development of HACCP plans and ongoing implementation of standard DON biosecurity protocols regarding detection and management of non-native species (e.g., coconut rhinoceros beetle), the potential for the introduction of new or spread of existing non-native species on Guam is substantially reduced. Therefore, there would be less than significant impacts to native wildlife species related to the potential introduction and establishment of non-native species with implementation of proposed construction activities associated with Alternative 5.
Damage of forested areas, particularly primary and secondary limestone forests, by non-native ungulates (i.e., deer and pigs) is a serious concern on Guam. Under Alternative 5, removal of large amounts of limestone forest currently used by ungulates would displace and concentrate ungulates into adjacent areas, resulting in even higher densities and potentially greater habitat damage. Potential impacts from changes in ungulate densities from construction projects within the same or similar habitat areas as proposed in this SEIS were addressed in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.2.1: North, page 10-115). In addition, the construction of the proposed NWF LFTRC would require the relocation of the ungulate exclosure fence that has been constructed in accordance with conservation measures identified during ESA section 7 consultation for a previous Air Force action (USFWS 2006b). The relocated ungulate exclosure fence would encompass a larger area and disturb a smaller acreage of limestone forest.

The implementation of the potential mitigation measures under the Vegetation section above would also benefit native wildlife species. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures.

**Special-Status Species: Federal ESA-Listed and Proposed Species and Critical Habitat**

Impacts to special-status species from the construction of the HG Range at Andersen South were discussed in Section 5.1.8.2 and were determined to be less than significant. The following discussion addresses those species that occur within the proposed ranges at NWF under Alternative 5.

**MARIANA FRUIT BAT.** Approximately 215 acres (87 ha) of Mariana fruit bat recovery habitat would be removed due to proposed construction activities at NWF under Alternative 5. This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

Additional potential direct temporary impacts to the Mariana fruit bat from construction activities are based on the distances from those activities that are likely to cause disturbance to this species (e.g., noise, human activity, lighting). The evaluation of fruit bat disturbance is based on the approach used by USFWS in previous ESA section 7 formal consultations and associated BOs (e.g., USFWS 2006b, 2010). These distances are: roosting habitat within 492 feet (150 m) and foraging habitat within 328 feet (100 m) from the activity (Wiles, personal communication 2006 and Janeke, personal communication 2006, respectively, as cited in USFWS 2006b).

The species is currently limited to the few areas on Guam away from human activities and with suitable habitat, primarily on federal lands on the NAVMAG and AAFB (JRM et al. 2012a, 2012b; JRM 2013; A. Brooke, NAVFAC Marianas, personal communication). However, illegal hunting, loss and degradation of native forest, predation by the brown treesnake, and the increased extirpation risk owing to the high vulnerability of very small populations continue to limit the potential recovery of the species on Guam (USFWS 2010a; JRM 2013). Based on the equilibrium/carrying capacity of snakes on Guam (Rodda and Savidge 2007), implementation of the proposed action is not expected to increase the likelihood of predation by the brown treesnake on Mariana fruit bats.

Although the loss of 215 acres (87 ha) of fruit bat recovery habitat on Guam would not preclude the recovery or survival of the fruit bat, it would reduce the total number of bats that the island can support. Given this loss of recovery habitat and the critically low numbers of bats on Guam, there would be significant but mitigable impacts to the Mariana fruit bat.
The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct long-term impacts of proposed construction activities on Mariana fruit bats with implementation of Alternative 5. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Pre-Construction Surveys.** Surveys would be completed within suitable fruit bat habitat 1 week prior to onset of construction activities following the USFWS-approved JRM protocol. If a fruit bat is present within 492 feet (150 m) of the project site, the work must be postponed until the bat has left the area.
- **Lighting Installation.** Lighting would be designed to meet minimum safety, sustainability, and AT/FP requirements. Either hooded or “night-adapted” lights would be installed at LFTRC Alternative 5 at NWF. Hooded lights would be used to the maximum extent practicable at all new roads and facilities within known fruit bat roost areas. Illumination of forest would be kept to an absolute minimum.

**Potential Mitigation Measures**

The same potential mitigation measures discussed previously under Vegetation (i.e., forest enhancement of 200 acres [82 ha] of limestone forest) would be applicable for the Mariana fruit bat and its recovery habitat. The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Mariana fruit bat. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

**Mariana Fruit Bat Critical Habitat.** Section 7 of the federal ESA requires federal agencies to insure that their actions are not likely to result in the destruction or adverse modification of designated critical habitat. In 1986, the USFWS and NMFS promulgated regulations governing interagency cooperation under ESA section 7. These regulations (50 CFR 402.02) defined “destruction or adverse modification” of critical habitat to mean “a direct or indirect alteration that appreciably diminishes the value of critical habitat for both the survival and recovery of a listed species. Such alterations include, but are not limited to, alterations adversely modifying any of those physical or biological features that were the basis for determining the habitat to be critical.” This definition was found to be invalid by the U.S. Court of Appeals for the 5th (2001) and 9th (2004) Circuits.

In response to these rulings and pending the adoption of any new regulatory definition of “destruction or adverse modification,” the USFWS provided guidance in 2004 regarding consultations concerning critical habitat (USFWS 2004b). The evaluation of effects to designated critical habitat should consider the statutory provisions of the ESA and not the regulatory definition at 50 CFR 402.02. USFWS (2004b) provided the following guidance to assist in applying these considerations in section 7(a)(2) consultations on federal actions that may affect designated critical habitat:
• Discuss the entire designated critical habitat area in terms of the biological and physical features that are essential to the conservation (discussion of “survival” in this and other sections of the adverse modification analysis is not appropriate) of the species. The analysis should identify and discuss the PCEs of the critical habitat.
• Describe how the PCEs essential to the conservation of the species are likely to be affected and, in turn, how that will influence the function and conservation role of the affected critical habitat unit.
• Discuss whether, with implementation of the proposed federal action, critical habitat would remain functional (or retain the current ability for the PCEs to be functionally established) to serve the intended conservation role for the species (USFWS 2004b).

The above guidance was used for the ESA section 7 analysis of impacts to designated Mariana fruit bat, Mariana crow, and Guam Micronesian kingfisher critical habitat in this SEIS.

The area within the southwestern portion of the critical habitat area, adjacent to the Guam NWR boundary, would be used for the relocation of the existing USFWS facilities that are currently located to the northeast, near Ritidian Point (see Figure 5.5.8-3). Two additional areas near Ritidian Point in the center of the critical habitat area are developed areas containing the existing NWR administrative buildings, roads, and parking lots. In accordance with the final rule designating critical habitat (USFWS 2004a), developed areas were not designated critical habitat; therefore, proposed construction activities within these two areas would not affect critical habitat.

The proposed area for the relocated USFWS facilities and associated road and parking lot contains 11 acres (5 ha) of primary limestone forest supporting both PCEs for fruit bat critical habitat (see Figure 5.5.8-3). Noise and disturbance-related construction impacts would be temporary in nature. The proposed 11-acre (5-ha) construction area is already subject to daily human disturbance due to aircraft operations and other DoD activities at AAFB, and its proximity to the access road to the Guam NWR, adjacent beaches, and private property to the southwest. In addition, appropriate BMPs would be implemented during construction to avoid and minimize impacts to fruit bats (e.g., pre-construction fruit bat surveys and installation of appropriate lighting in the vicinity of fruit bat habitat [e.g., hooded lights will be used to the maximum extent possible to avoid and minimize the illumination of forest]). Although construction would directly impact 11 acres (5 ha) of designated critical habitat, the remaining critical habitat would remain functional (or retain the current ability for the PCEs to be functionally established) to serve the intended conservation role for the fruit bat. Accordingly, given the above, construction impacts would not appreciably diminish the value of the critical habitat for both the survival and recovery of the Mariana fruit bat.

Additional potential impacts to Mariana fruit bat critical habitat could occur during temporary construction activities (e.g., noise, lighting, and general human disturbance) associated with the proposed ranges at NWF that would be adjacent to critical habitat. However, the 2004 designation of critical habitat by the USFWS (USFWS 2004a) stated that “the presence of auditory or visual human disturbances does not affect the presence of the primary constituent elements used to define critical habitat.” This area is already subject to daily human disturbance due to aircraft operations and other DoD activities at AAFB, and its proximity to the access road to the Ritidian Unit of the Guam NWR, adjacent beaches, and private property to the southwest. Implementation of BMPs (e.g., installation of hooded lights in the vicinity of fruit bat critical habitat) will be used to the maximum extent possible to avoid and minimize the illumination of forest and critical habitat.
In summary, impacts to 11 acres (5 ha) of fruit bat critical habitat as a result of construction activities associated with the relocation of USFWS facilities and construction of LFTRC would be less than significant and the remaining area of critical habitat would remain functional to serve the intended conservation role for the Mariana fruit bat.

MARIANA CROW. The Mariana crow is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the crow is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for reintroduction of the crow, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the crow is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative 5, impacts to the crow would be limited to recovery prospects. If crows are reintroduced and exposed to construction activities under Alternative 5, they may be disturbed (DON 2014).

Although the crow no longer occurs on Guam, approximately 215 acres (87 ha) of crow recovery habitat would be removed due to proposed construction activities at NWF under Alternative 5. This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

Although the loss of 215 acres (87 ha) of crow recovery habitat on Guam would not preclude the recovery of the crow should it be reintroduced to Guam in the future, it would reduce the total number of crows that the island can support. If and when the crow is reintroduced to Guam, the best available information indicates project-related noise would not further reduce the amount of recovery habitat suitable for this species’ breeding, feeding and sheltering (USFWS 2010a). Given this loss of recovery habitat, there would be significant but mitigable impacts to the recovery of the Mariana crow.

The following BMPs and potential mitigation measures may be implemented to avoid, reduce, and mitigate potential direct long-term impacts of proposed construction activities on the recovery of the Mariana crow with implementation of Alternative 5. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

**Potential Mitigation Measures**

- **Brown Treesnake Suppression or Eradication.** See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW for a detailed description of the brown treesnake suppression or eradication program.
• The same potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 200 acres [82 ha] of limestone forest) would be applicable for the Mariana crow and its recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Mariana crow, should it be reintroduced to Guam in the future.

Mariana Crow Critical Habitat. As the Mariana crow is currently extirpated from Guam, designated crow critical habitat is considered unoccupied. Per the previous discussion for the Mariana fruit bat, only one area of designated critical habitat would be impacted by construction activities under Alternative 5 (Figure 5.5.8-3). The existing USFWS facilities of the Ritidian Unit of the Guam NWR would be relocated to an area within the southwestern portion of the critical habitat area, adjacent to the Guam NWR boundary. This area consists of primary limestone forest supporting PCEs 1 and 3 for crow critical habitat. Given the presence of the existing access road within this area, the area does not support PCE 2: areas of limestone forest to allow nesting at least 950 feet (290 m) from the nearest road.

The proposed area for the relocated USFWS facilities and associated road and parking lot contains 11 acres (5 ha) of primary limestone forest supporting PCEs for crow critical habitat (see Figure 5.5.8-3). Noise and disturbance-related construction impacts would be temporary in nature. The proposed 11-acre (5-ha) construction area is already subject to daily human disturbance due to aircraft operations and other DoD activities at AAFB, and its proximity to the access road to the Guam NWR, adjacent beaches, and private property to the southwest. Although construction would directly impact 11 acres (5 ha) of designated critical habitat, the remaining critical habitat would remain functional (or retain the current ability for the PCEs to be functionally established) to serve the intended conservation role for the crow. Accordingly, given above, construction impacts would not appreciably diminish the value of the critical habitat for the recovery of the Mariana crow.

Additional potential impacts to Mariana crow critical habitat could occur during temporary construction activities (e.g., noise, lighting, and general human disturbance) associated with the proposed ranges at NWF that would be adjacent to critical habitat. However, the 2004 designation of critical habitat by the USFWS (USFWS 2004a) stated that “the presence of auditory or visual human disturbances does not affect the presence of the primary constituent elements used to define critical habitat.”

In summary, impacts to 11 acres (5 ha) of crow critical habitat as a result of construction activities associated with the relocation of USFWS facilities within the Ritidian Unit of the Guam NWR and construction of LFTRC would be less than significant and the remaining area of critical habitat would remain functional to serve the intended conservation role for the Mariana crow.

GUAM MICRONESIAN KINGFISHER. The kingfisher is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the kingfisher is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the kingfisher, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the kingfisher is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative 5, impacts to the kingfisher would be limited to
recovery prospects. If kingfishers are reintroduced and exposed to construction activities under Alternative 5, they may be disturbed (DON 2014).

Although the kingfisher no longer occurs on Guam, approximately 215 acres (87 ha) of kingfisher recovery habitat would be removed due to proposed construction activities under Alternative 5. This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

Although this loss of recovery habitat on Guam would not preclude the recovery of the kingfisher should it be reintroduced to Guam in the future, it would reduce the total number of kingfishers that the island can support. Given this loss of recovery habitat, there would be significant but mitigable impacts to the recovery of the Guam Micronesian kingfisher.

The following BMPs and potential mitigation measures may be implemented to avoid, minimize, and mitigate potential direct and indirect long-term impacts of proposed construction activities on the recovery of the Guam Micronesian kingfisher with implementation of Alternative 5. Final mitigation measures will be identified in the ROD after resource agency consultations are completed.

Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

Potential Mitigation Measures

- **Brown Treesnake Suppression or Eradication.** See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW for a detailed description of the brown treesnake suppression or eradication program.
- The same potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 200 acres [82 ha] of limestone forest) would be applicable for the kingfisher and its recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Guam Micronesian kingfisher, should it be reintroduced to Guam in the future.

As part of the ESA section 7 consultation process, the DON and the USFWS entered into an MOA which would, if the preferred alternative is chosen, facilitate kingfisher conservation goals. In the MOA, the DON agreed to designate approximately 5,234 acres (2,118 ha) under the custody and control of the DoD in northern Guam to a status that will provide durable habitat protection needed to support native habitat restoration and land management for the survival and recovery of the kingfisher. Consistent with the JRM INRMP developed in accordance with Section 101 of the Sikes Act, the DON agreed to actively restore
native habitat and manage, in collaboration with the USFWS, the 5,234 acres (2,118 ha) consistent with DoD’s obligations under ESA section 7(a) and the Sikes Act to benefit the survival and recovery of the kingfisher. The DON would work cooperatively with the USFWS to identify, develop and implement specific management activities and projects on these 5,234 acres (2,118 ha) to support the reintroduction and recovery of the kingfisher.

These 5,234 acres (2,118 ha) have been identified by the USFWS as habitat for the kingfisher and needed to offset impacts of the proposed action. The DON and USFWS recognize that the designation of the 5,234 acres (2,118 ha) may also provide a conservation benefit to other ESA-listed species with similar habitat requirements (e.g., Mariana crow, Mariana fruit bat).

**Guam Micronesian Kingfisher Critical Habitat.** As the Guam Micronesian kingfisher is currently extirpated from Guam, designated kingfisher critical habitat is considered unoccupied. Per the previous discussion for the Mariana fruit bat, only one area of designated critical habitat would be impacted by construction activities under Alternative 5 (see Figure 5.5.8-3). The existing USFWS facilities within the Ritidian Unit of the Guam NWR would be relocated to an area within the southwestern portion of the critical habitat area, adjacent to the Guam NWR boundary. This area consists of primary limestone forest supporting all PCEs for kingfisher critical habitat.

The proposed area for the relocated USFWS facilities and associated road and parking lot contains 11 acres (5 ha) of primary limestone forest supporting PCEs for kingfisher critical habitat (see Figure 5.5.8-3). Noise and disturbance-related construction impacts would be temporary in nature. The proposed 11-acre (5-ha) construction area is already subject to daily human disturbance due to aircraft operations and other DoD activities at AAFB, and its proximity to the access road to the Guam NWR, adjacent beaches, and private property to the southwest. Although construction would directly impact 11 acres (5 ha) of designated critical habitat, the remaining critical habitat would remain functional (or retain the current ability for the PCEs to be functionally established) to serve the intended conservation role for the kingfisher. Accordingly, given the above, construction impacts would not appreciably diminish the value of the critical habitat for the recovery of the Guam Micronesian kingfisher.

Additional potential impacts to kingfisher critical habitat could occur during temporary construction activities (e.g., noise, lighting, general human disturbance) associated with the proposed ranges at NWF that would be adjacent to critical habitat. However, the 2004 designation of critical habitat by the USFWS (USFWS 2004a) stated that “the presence of auditory or visual human disturbances does not affect the presence of the primary constituent elements used to define critical habitat.”

In summary, impacts to 11 acres (5 ha) of kingfisher critical habitat as a result of construction activities associated with the relocation of USFWS facilities and construction of LFTRC would be less than significant and the remaining area of critical habitat would remain functional to serve the intended conservation role for the Guam Micronesian kingfisher.

**GUAM RAIL.** The Guam rail is extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of the rail is reasonably certain to occur and it is likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of the rail, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the rail is successfully re-introduced and then has the potential to be exposed to construction activities under Alternative 5, impacts to the rail would be limited to recovery prospects. If rails are reintroduced and exposed to construction activities under Alternative 5, they may be disturbed (DON 2014).
Although the rail no longer occurs on Guam, approximately 82 acres (33 ha) of rail recovery habitat would be removed due to proposed construction activities under Alternative 5. This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species.

This loss of recovery habitat on Guam would not preclude the recovery or survival of the rail should it be reintroduced to Guam in the future, and it would not substantially reduce the total number of rails that the island can support. Given this small loss of recovery habitat on Guam, there would be less than significant impacts to the Guam rail with implementation of proposed construction activities associated with Alternative 5.

The following BMPs may be implemented to avoid and reduce potential long-term impacts of proposed construction activities on the recovery of the Guam rail with implementation of Alternative 5.

**Best Management Practices**

- **HACCP Plan.** See Section 4.1.8.2 under Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
- **Brown Treesnake Interdiction.** See Section 4.1.8.2, Construction, Wildlife - Native Species for a detailed description of the brown treesnake interdiction program.

In addition, potential mitigation measures proposed above for vegetation and the Mariana crow would benefit the Guam rail.

- **Brown Treesnake Suppression or Eradication.** See Section 4.1.8.2, Construction, Special-Status Species, MARIANA CROW for a detailed description of the brown treesnake suppression or eradication program.
- **The same potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 200 acres [82 ha] of limestone forest) would be applicable for the rail and its recovery habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk). The anticipated benefit of implementing these mitigation measures is improved habitat quality for native flora and fauna, including the Guam rail, should it be reintroduced to Guam in the future.**

**MARIANA EIGHT-SPOT BUTTERFLY.** Host plants and adult, immature, and egg stages of the eight-spot butterfly have been observed within the proposed MPMG and Non-standard Small Arms ranges associated with Alternative 5 (see Figure 5.5.8-3) (NAVFAC Marianas 2013; NAVFAC Pacific 2013b). With implementation of appropriate BMPs to avoid and minimize potential impacts to eight-spot butterflies (e.g., pre-construction butterfly and host plant surveys within the proposed range areas and salvage/relocation of host plants, larvae or eggs; see Table 2.8-1), there would be less than significant impacts to the Mariana eight-spot butterfly with implementation of proposed construction activities under Alternative 5. In addition, implementation of the potential mitigation measures described above under Vegetation (i.e., forest enhancement of 200 acres [82 ha] of limestone forest) would also benefit the
survival the eight-spot butterfly. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species, including eight-spot butterfly host plants.

GUAM TREE SNAIL. As discussed previously in the Affected Environment section (see 5.5.8.1, Special-Status Species: Federal ESA-Listed and Proposed Species and Designated Critical Habitat), the Guam tree snail has not been observed within the proposed impacted areas of the NWF LFTRC alternative and therefore would not be impacted by proposed construction activities. However, the USFWS regularly conducts tree snail surveys at 88 stations along 9 transects within the Ritidian Unit of the Guam NWR. Two survey stations along one transect lie within the footprint of the proposed beach access near the proposed location for relocated USFWS facilities and would be removed from future survey efforts (see Figure 2.5-6). Based on existing USFWS survey data, tree snails have not been observed at these two survey stations (J. Cruce, Wildlife Refuge Specialist, Guam NWR, USFWS, personal communication, 2014). The loss of these two survey stations would not be a significant impact to the long-term survey effort by the USFWS.

SERIANTHES TREE. The only known mature Serianthes tree on Guam is located on the northwest corner of the potential impacted area associated with the proposed MPMG Range (see Figure 5.5.8-2). Current literature regarding the protection of trees from construction activities recommend a protective buffer based on the diameter at breast height (dbh) of the subject tree (Oregon State University 2009; University of Hawaii 2010; Johnson 2013). This buffer is related to the “critical root radius” approach which is calculated by measuring the dbh in inches. For each inch of dbh, allow for 1.5 feet (0.5 m) of critical root radius for sensitive, older, or unhealthy trees, or 1 foot (0.3 m) for tolerant, younger, healthy trees to ensure protection of the root zone. Therefore, based on the current dbh of 22.4 inches (57 cm) for the subject Serianthes at NWF, the buffer would be approximately 34 feet (10 m). To avoid any impacts to this tree, a minimum buffer of 100 feet (30 m) would be established around the tree and no activities would be permitted within this buffer. Therefore, there would be no impacts to the Serianthes tree with implementation of the proposed construction activities associated with Alternative 5.

Approximately 177 acres (71 ha) of Serianthes recovery habitat would be removed due to proposed construction activities under Alternative 5. This area is included in the impacts to vegetation and Overlay Refuge lands discussed above. See Section 3.8.3.2 for a discussion of recovery habitat and its use as a criterion for assessing impacts to ESA-listed species. Although this loss of recovery habitat on Guam would not preclude the recovery of Serianthes, it would reduce the total number of Serianthes that the island can support. Given this loss of recovery habitat on Guam, there would be significant but mitigable impacts to the recovery of Serianthes on Guam with implementation of proposed construction activities associated with Alternative 5.

The following BMPs may be implemented to avoid and minimize, potential direct long-term impacts of proposed construction activities on the recovery of Serianthes with implementation of Alternative 5.

Best Management Practices

- **HACCP Plan.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of HACCP planning.
- **Biosecurity Outreach and Education.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of biosecurity outreach and education.
- **Contractor Education Program.** See Section 4.1.8.2, Construction, Vegetation for a detailed description of the contractor education program.
• The one remaining adult *Serianthes* tree at NWF is in poor condition due to termites and rotting at the base. The tree is leaning which renders it more susceptible to snapping or toppling in the event of a catastrophic typhoon. Guide wires would be installed to support the tree at NWF thereby reducing the potential for its collapse.

The implementation of the potential mitigation measures discussed above under Vegetation (i.e., forest enhancement of 200 acres [82 ha] of limestone forest) would benefit *Serianthes* habitat. In particular, the objectives of ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures. Forest enhancement would also support natural regeneration and seed propagation, reduce erosion, and increase water retention (i.e., reduces fire risk).

*Bulbophyllum guamense* and *Psychotria malaspiniae*. There is a reported single occurrence of each species within the northern portion of the MPMG range at NWF (see Figure 5.5.8-3). Proposed construction activities would potentially impact 1 individual *B. guamense* out of approximately 250 individuals on Guam. Although *P. malaspiniae* has been reported from the NWF area, no individuals have been seen in the past 5 years (USFWS 2014a). If detected during pre-construction surveys, both species would be salvaged to the maximum extent practicable and translocated to suitable habitat (see Section 2.8). With the implementation of BMPs, such as potential translocation of *B. guamense* and *P. malaspiniae* to suitable habitat, there would be less than significant impacts to both species with implementation of the construction activities associated with Alternative 5. In addition, the implementation of the potential mitigation measures under the Vegetation section above would also benefit the survival of these species. In particular ungulate management, control/suppression of invasive plants, and outplanting of native species proposed under the forest enhancement mitigation measures.

**Special-Status Species: Guam-Listed and SOGCN**

Guam-listed species and SOGCN are also ESA-listed species and potential impacts to these species are discussed above.

**Operation **

*Vegetation*. With implementation of BMPs (see previous discussion of construction impacts under Vegetation), including ongoing implementation of standard DON and commercial biosecurity protocols (e.g., Port of Guam, A.B. Won Pat International Airport) regarding detection and management of non-native species, invasive species outreach and education, and 1-year post-construction monitoring to evaluate effectiveness of HACCP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of Alternative 5 is considered unlikely. Therefore, there would be less than significant impacts to vegetation with operation of the proposed LFTRC under Alternative 5.

Fire potential would increase due to proposed live-fire range operations. Fire can result in direct effects to vegetation by increasing erosion, allowing for the establishment of non-native species, and altering wildlife habitat by reducing food resources, breeding habitat, and shelter. Native plants and their habitats on Guam are adapted to a humid, tropical climate and are not adapted to a fire driven ecosystem (USFWS 2008a).

As a BMP and in accordance with range safety protocols, a Range Fire Management Plan would be prepared, based on the DON’s Wildland Fire Management Plan (Nelson 2008) (see Section 2.8). It would include protocols for monitoring fire conditions and adjusting training as needed (e.g., certain types of training may be disallowed under certain fire conditions), and location and management of firebreaks,
fire-fighting roads, and a fire fighting water system. Units undergoing training would be briefed on requirements suitable to the conditions of the day and protocols should a fire occur (e.g., specifying how the range would shut down and how fire suppression action would be taken). With implementation of the Range Fire Management Plan, which establishes management and fire suppression and emergency response procedures, potential impacts from range-related wildfires would be less than significant. The USFWS concluded in their BO for the 2010 Final EIS that they anticipated that no additional vegetation would be lost due to wildfires igniting as a result of proposed live-fire training operations (USFWS 2010a). Therefore, there would be less than significant impacts to vegetation from operation of LFTRC Alternative 5.

Terrestrial Conservation Areas. Impacts to terrestrial conservation areas from the operation of the HG Range at Andersen South were discussed in Section 5.1.8.2. As Andersen South does not contain any terrestrial conservation areas, there would be no impacts.

Modeled noise levels greater than 55 dB ADNL from proposed live-fire range operations would overlie approximately 1,691 acres (684 ha) of Overlay Refuge lands on AAFB NWF (Table 5.5.8-4 and Figure 5.5.8-4). Overlay Refuge lands were established for the purpose of conserving and protecting ESA-listed species and other native flora and fauna, maintaining native ecosystems, and the conserving native biological diversity, recognizing that the primary purpose of lands within the Overlay Refuge is to support the national defense missions of the Navy and Air Force.

Existing noise levels at NWF are composed of airfield operations in flight tracks going to and from AAFB; aviation training by H-60, H-46, H-53, V-22, H-1 and C-130 aircraft at NWF; and ground-based training using pyrotechnics, ground burst simulators, smoke grenades, and 40-pound cratering charges. Although there would be noise due to proposed LFTRC activities combined with the existing aviation and ground-based training, the current and proposed noise-generating activities would not result in a significant change in the noise environment at NWF and there would not be a loss of the conservation function of Overlay Refuge lands at NWF.

Access to the Ritidian Unit of the Guam NWR and the USGS Brown Treesnake Research Exclosure at NWF will be granted at approved times such as when lands are not being used for military training. Upon entering an operational phase, coordination of specific dates for range usage would be scheduled by Range Operations. With appropriate coordination and in accordance with DoD security protocols, the DON would allow research and monitoring of biological resources by local, university, and federal researchers on Guam NWR and DON lands. Therefore, the areas would remain functional to serve their intended conservation role for listed and at-risk species. Additionally, pursuant to pending legislation in the FY 2015 National Defense Authorization Act, the DON and the USFWS will enter into an agreement that provides for the management of the Ritidian Unit to ensure sensitive resources are appropriately protected and managed.

Therefore, there would be less than significant impacts to terrestrial conservation areas with implementation of Alternative 5.

Wildlife - Native Species. Operational impacts to native wildlife would include an increase in noise and lighting. These potential impacts were evaluated in the 2010 Final EIS (Volume 2, Chapter 10: Terrestrial Biological Resources, Section 10.2.2.2: Central, page 10-129) for a similar proposed action, and were found to be not significant. With implementation of BMPs (see previous discussion of construction impacts under Vegetation), including ongoing implementation of standard DON and commercial biosecurity protocols (e.g., Port of Guam, A.B. Won Pat International Airport) regarding detection and management of non-native species, invasive species outreach and education, and 1-year post-construction monitoring to evaluate effectiveness of HACCP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of the proposed LFTRC under Alternative 5 is considered unlikely. The DON recognizes the USFWS’ ongoing concern regarding potential spread of the brown treesnake. The DON will consult with USFWS under ESA section 7 to determine if additional brown treesnake interdiction measures are warranted and applicable. In addition, lighting associated with the range and support areas would be hooded or shielded to the maximum extent practicable to prevent unnecessary light beyond operational areas. Therefore, there would be less than significant impacts to native wildlife with operation of the proposed LFTRC under Alternative 5.

Special-Status Species: Federal ESA-Listed and Proposed Species and Critical Habitat

MARIANA FRUIT BAT. The assessment of noise levels associated with the proposed HG Range at Andersen South was previously discussed in Section 5.1.8.2. There would be no impacts to Mariana fruit bats from noise associated with operation of the HG Range.

For those species of fruit bats that have been tested for hearing sensitivity, their audiograms are very similar to those of humans, with similar upper and lower frequency limits and hearing threshold levels (Calford et al. 1995; Koay et al. 1998; Heffner et al. 2006). Therefore, it is likely that noise from live-fire operations at the proposed ranges would be heard by fruit bats as it would be heard by humans.

The USFWS established 60 dB and 93 dB as two thresholds of biological significance based on their review of impacts of noise to wildlife. Noise levels above 60 dB have been found to affect acoustic communication, breeding biology, survival of young, and non-auditory bird and mammal physiology. Noise levels above 93 dB may temporarily or permanently affect hearing (USFWS 2010a). No species would be exposed to noise levels of 93 dB or greater under the proposed action. While noise levels may approach 93 dB in the immediate vicinity of the firing of an individual weapon, fruit bats or other wildlife species would not be in proximity to the live-fire event given the location and nature of weapons firing within a developed range area.

Responses to noise can vary among individuals as a result of habituation where after a period of exposure to a stimulus, an animal stops responding to the stimulus. In general, a species can often habituate to human-generated noise when the noise is not followed by an adverse impact. Even when a species appears to be habituated to a noise, the noise may produce a metabolic or stress response (increased heart rate results in increased energy expenditure) though the response may or may not lead to changes in overall energy balance. Anthropogenic noise disturbance is known to alter animal behavioral patterns and lead to population declines (Barber et al. 2011; Francis and Barber 2013; McGregor et al. 2013).

In addition to noise level, the frequency and regularity of the noise also affect species sensitivity. That is, different types of noise sources will produce different effects on different species. Noise from aircraft overflights may not produce the same response from a wildlife species as noise from a land-based noise source such as a vehicle, chainsaw, or gun shot. Wildlife species often do not react only to a noise source but more importantly to the visual component associated with that noise source. Nesting birds will react to a noise source by tilting their head, becoming alert, etc. but often do not leave the nest or perch until
there is a visual connection with the noise source. For example, birds may not react to just the sound of a chainsaw, but when that sound is coupled with a human walking near the bird, the bird will flush. This is also shown in reactions by various species to aircraft overflights (airplanes and helicopters). An overflight with just a sound component does not elicit a strong response, but if an animal hears and then sees the aircraft, the bird will more likely flush and move away (Manci et al. 1988; USFWS 1992; Krausman et al. 1993; Bowles 1995). In other words, human intrusions near roost sites, nests, foraging areas, etc. (e.g., timber harvesting, hiking, hunting) are readily detectable and substantial (USFS 1992).

Species that are commonly hunted often demonstrate behavioral (e.g., flushing, startle response) or physiological responses (e.g., increased heart rates, increased respiration rates) to gunshot sounds (Larkin et al. 1996). Knight et al. (1987) found that American crows nesting in urban areas were less wary of people than American crows nesting in rural habitat and attributed the difference to the hunting of rural crows. Barron et al. (2012) found that American crows avoided areas with live-fire exercises in a similar fashion and suggested that species hunted by humans will be more adversely affected by human activity, including military training (e.g., live-fire training) than species that are not hunted.

As stated by Morton and Wiles (2002), “Poaching is a particularly insidious activity because not only does it impact fruit bats through mortality, it reinforces behavioral avoidance of humans. Consequently, roosting or foraging fruit bats that might not otherwise be disturbed by some human activities … may become unduly sensitized to them because of illegal hunting.” Based on observations on Guam and Rota, fruit bats have abandoned areas where hunting has occurred and did not return even though no further hunting or gunshots occurred within the area for months after (Janeke 2006; AAFB 2008b; USFWS 2009a; Mildenstein and Mills 2013). In addition, anecdotal evidence from numerous individuals who have conducted fruit bat research on Guam and the CNMI for many years indicate that fruit bats do avoid areas that have been previously subjected to hunting and also areas that experience live-fire activities (G. Wiles, Washington Department of Fish and Wildlife, personal communication, 2014; T. Mildenstein, University of Montana, personal communication, 2014; D. Janeke, HDR, Inc., personal communication, 2014; N. Johnson, Marianas Conservation Unlimited, personal communication, 2014). For example, during fruit bat monitoring at AAFB near the CATM range as part of a larger study monitoring the effects of aircraft overflights on fruit bats and crows (JRM et al. 2012b), N. Johnson observed flying fruit bats avoid the CATM range by 300-400 m when live-fire operations were being conducted (N. Johnson, Marianas Conservation Unlimited, personal communication, 2014).

However, a species can also habituate to human-generated noise when the noise is not followed by an adverse impact. While fruit bats may avoid an area subjected to hunting and the associated gun shots, fruit bats, like most wildlife species, will also learn that if a disturbance or sound does not produce an adverse effect (e.g., mortality), then they can habituate to that disturbance or sound and will not show an adverse reaction (e.g., flying away, avoiding the area) (Boyle and Samson 1985; Francis and Barber 2013).

Most of the effects of noise are mild enough that they may never be detectable as variables of change in population size or population growth against the background of normal variation (Bowles 1995). Other environmental variables (e.g., predators, weather, changing prey base, ground-based disturbance) may influence reproductive success and confound the ability to identify the ultimate factor in limiting productivity of a certain species, area, or region (Smith et al. 1988).

Based on identified recovery habitat for the Mariana fruit bat (USFWS 2010b), noise levels of 60 dB ADNL and greater would overlie 1,101 acres (446 ha) of recovery habitat in the vicinity of Alternative 5 (Table 5.5.8-5 and Figure 5.5.8-4).

Given the ongoing poaching of fruit bats on Guam, it is likely that those fruit bats that currently occur on Guam will avoid areas of live-fire training as they may have experienced a poaching event. While there is the potential for eventual habitation by fruit bats to LFTRC live-fire activities, fruit bats are expected to initially avoid areas of live-fire training activities. Therefore, fruit bats may temporarily avoid approximately 1,101 acres (446 ha) of recovery habitat due to proposed live-fire range operations. However, proposed live-fire operations at the LFTRC are not continuous and would occur between 7:00 a.m. and 7:00 p.m. for 39 weeks per year, and night operations (estimated to occur 2 nights per week over 39 weeks per year) would occur between 7:00 p.m. and 10:00 p.m. or 6:00 a.m. and 7:00 a.m. In addition, live-fire operations would not physically impact recovery habitat. This temporary avoidance of recovery habitat on Guam would not preclude the recovery or survival of the fruit bat, and it would not substantially reduce the total number of fruit bats that the island can support.

With implementation of BMPs (see previous discussion of construction impacts under Vegetation), including ongoing implementation of standard DON and commercial biosecurity protocols (e.g., Port of Guam, A.B. Won Pat International Airport) regarding detection and management of non-native species, invasive species outreach and education, and 1-year post-construction monitoring to evaluate effectiveness of HACCP, the potential for the introduction of new or spread of existing non-native species on Guam during the operation of Alternative 5 is considered unlikely. Therefore, there would be less than significant impacts to the Mariana fruit bat with implementation of proposed operational activities associated with Alternative 5.

Mariana Fruit Bat Critical Habitat. Potential impacts to Mariana fruit bat critical habitat could occur during range operations (e.g., noise, lighting, and general human disturbance) associated with the proposed ranges at NWF that would be adjacent to critical habitat. However, the 2004 designation of critical habitat by the USFWS (USFWS 2004a) stated that “the presence of auditory or visual human disturbances does not affect the presence of the primary constituent elements used to define critical habitat.” This area is already subject to daily human disturbance due to aircraft operations and other DoD activities at AAFB, and its proximity to the access road to the Guam NWR, adjacent beaches, and private property to the southwest. Implementation of BMPs (e.g., installation of hooded lights in the vicinity of fruit bat critical habitat) will be used to the maximum extent possible to avoid and minimize the illumination of forest and critical habitat. Therefore, the operation of Alternative 5 would result in less than significant impacts to fruit bat critical habitat and critical habitat would remain functional to serve the intended conservation role for the fruit bat.

MARIANA CROW, GUAM RAIL, AND GUAM MICRONESIAN KINGFISHER. These species are extirpated and no longer present on Guam, due primarily to predation by the brown treesnake. The USFWS, however, has advised the DON that it is reasonably certain that the effects of the proposed action are likely to persist during the lifespan of the proposed action and overlap the period when reintroduction of these species is reasonably certain to occur and the species are likely to be exposed to the effects of the action. There are currently neither projected dates for re-introduction of these species, nor successful suppression of the brown treesnake to a level which would support re-introduction. Until the crow, rail, and kingfisher are successfully re-introduced and then have the potential to be exposed to operational activities under
Alternative 5, there would be no impact to these species. If the species are reintroduced and exposed to LFTRC operational activities under Alternative 5, they may be disturbed.

Mariana Crow and Guam Micronesian Kingfisher Critical Habitat. Potential impacts to Mariana crow and Guam Micronesian kingfisher critical habitat would be the same as previously discussed for the fruit bat. Therefore, the operation of Alternative 5 would result in less than significant impacts to crow and kingfisher critical habitat and critical habitat would remain functional to serve the intended conservation role for both species.

GUAM TREE SNAIL. As discussed previously in the Affected Environment section (see 5.5.8.1, Special-Status Species: Federal ESA-Listed and Proposed Species and Designated Critical Habitat), the Guam tree snail has not been observed within the proposed impacted areas of the NWF LFTRC alternative. However, the USFWS regularly conducts tree snail surveys at 88 stations along 9 transects within the Ritidian Unit of the Guam NWR (J. Cruce, Wildlife Refuge Specialist, Guam NWR, USFWS, personal communication, 2014). Two survey transects composed of 20 survey stations would be within the proposed SDZs of the LFTRC at NWF. Upon entering an operational phase, coordination of specific dates for range usage would be scheduled by Range Operations. With appropriate coordination and in accordance with DoD security protocols, the DON would allow research and monitoring of biological resources by local, university, and federal researchers within the SDZs and DON lands. Therefore, the areas would remain functional to serve their intended conservation role for listed and at-risk species. Additionally, pursuant to pending legislation in the FY 2015 National Defense Authorization Act, the DON and the USFWS will enter into an agreement that provides for the management of the Ritidian Unit to ensure sensitive resources (e.g., tree snails) are appropriately protected and managed. Therefore, there would be less than significant impacts to tree snail research and management with implementation of Alternative 5.

MARIANA EIGHT-SPOT BUTTERFLY. Some species of tropical butterflies have well-developed ears on their wings and can detect sounds at the same frequencies that humans can hear. It is hypothesized that the butterflies are listening to the flight sounds or foraging calls of predatory birds (Lane et al. 2008; Yack 2012). Given the low numbers of forest birds currently on Guam due to the brown treesnake, masking of the flight sounds or foraging calls of predatory birds due to noise from proposed construction activities would not make eight-spot butterflies more susceptible to predation.

Fire potential would increase due to proposed live-fire range operations. Fire can result in direct effects to vegetation by increasing erosion, allowing for the establishment of non-native species, and altering wildlife habitat by reducing food resources, breeding habitat, and shelter. Native plants and their habitats on Guam are adapted to a humid, tropical climate and are not adapted to a fire driven ecosystem (USFWS 2008a).

As a BMP and in accordance with range safety protocols, a Range Fire Management Plan would be prepared, based on the DON’s Wildland Fire Management Plan (Nelson 2008) (see Section 2.8). It would include protocols for monitoring fire conditions and adjusting training as needed (e.g., certain types of training may be disallowed under certain fire conditions), and location and management of firebreaks, fire-fighting roads, and a fire fighting water system. Units undergoing training would be briefed on requirements suitable to the conditions of the day and protocols should a fire occur (e.g., specifying how the range would shut down and how fire suppression action would be taken). With implementation of the Range Fire Management Plan, which establishes management and fire suppression and emergency response procedures, potential impacts from range-related wildfires would be less than significant. The USFWS concluded in their BO for the 2010 Final EIS that they anticipated that no additional vegetation
would be lost due to wildfires igniting as a result of proposed training operations (USFWS 2010a). Therefore, as operation of the range would not remove additional vegetation (e.g., host plants), there would be less than significant impacts to the Mariana eight-spot butterfly with implementation of proposed range operations under Alternative 5.

**Serianthes Tree.** The only known mature *Serianthes* tree on Guam is located on the northwest corner of the potential impacted area associated with the proposed MPMG Range (see Figure 5.5.8-2). To avoid any impacts to this tree, a minimum buffer of 100 feet (30 m) would be established around the tree and no activities would be permitted within this buffer. In addition, the DON will coordinate with the USFWS regarding access to the tree for research/conservation purposes. Therefore, there would be no impacts to *Serianthes* tree or recovery habitat with implementation of the proposed operations associated with Alternative 5.

**Special-Status Species: Guam-Listed and SOGCN**

Guam-listed species and SOGCN are also ESA-listed species and potential impacts to these species are discussed above.

### 5.5.9 Marine Biological Resources

**5.5.9.1 Affected Environment**

The description of the affected environment for marine biological resources around the proposed Alternative 5 is consistent with the summary provided for the proposed AAFB cantonment and housing Alternative C in Section 4.3.9.1. The primary difference in the affected environment between the NWF LFTRC and the Alternative C cantonment and housing location is that the Alternative C footprint is entirely onshore. SDZs for the proposed Alternative 5 extend offshore, into the Guam NWR - Ritidian Unit, which includes 401 acres (162 ha) of submerged lands at Ritidian Point from the high tide mark out to the 100-foot (30-m) bathymetric contour, lies offshore to the north (Figure 5.5.9-1).

**5.5.9.2 Environmental Consequences**

**Construction**

The environmental consequences for marine biological resources as a result of construction of Alternative 5 are consistent with the summary provided for the proposed AAFB cantonment/family housing alternative in Section 4.3.9.2.

There is no in-water construction work proposed for the construction of Alternative 5. Therefore, there are no anticipated direct impacts to marine resources. The measures used to minimize potential impacts from construction activities, including appropriate resource agency specific BMPs, construction and industrial permit BMPs (e.g., hooded lighting and limiting construction activities to daylight hours), USACE permit conditions, and general marine resources protective measures, are described in the 2010 Final EIS (Volume 7 and Volume 2, Chapter 11: Marine Biological Resources, Section 11.2: Environmental Consequences, pages 11-70 to 11-71) and summarized in Chapter 2 of this SEIS. Additional measures are described by NMFS to minimize impacts to EFH and ESA listed species as recommended conservation measures and are summarized under EFH and special status species in environmental consequences for operations below.
Figure 5.5.9-1
Overview of Sensitive Marine Biological Resources and Nearshore Habitat - NWF LFTRC Alternative 5

Legend
- DoD Property
- LFTRC Alternative 5 Impacted Area
- Ritidian Unit within SDZ
- Surface Danger Zone (SDZ)
- Marine Management Area Boundary

Sensitive Biological Resources:
- Green & Hawksbill Sea Turtle Sighting
- Potential Sea Turtle Nesting Area
- 50-m isobath
- 200-m isobath

Land Use:
- Coral, 10%-<50%
- Coral, 50%-<90%
- Coralline Algae
- Macroalgae
- Turf Algae
- Unconsolidated Sediment
Increased recreational use of the marine resources near the Guam NWR - Ritidian Unit may occur via boat and beach accessible trails by construction workers. However, contract construction personnel would be issued base passes for official business only and these restrictions would be specified in construction contracts.

The DON would educate construction workers via environmental awareness training on the importance of coastal ecosystems and the proper way to interact with those resources to avoid and minimize damage to reefs typically caused by anchors, reef-walkers, or scuba diving, snorkeling, and fishing activities around Guam. The above measures would reduce indirect impacts by the construction workforce on marine resources to less than significant.

**Operation**

Potential impacts to marine biological resources as a result of operation of the proposed live-fire training ranges and associated range operation and control facilities at NWF are assessed below, but are generally as described in the 2010 Final EIS for the Route 15 alternatives (Volume 2, Chapter 11: Marine Biological Resources, Section 11.2.2.2: Central, pages 11-85 to 11-92).

For analytical purposes, a very small number of rounds fired at all proposed ranges would fall outside the range footprint, but within the SDZ. This is based on ricochets, not direct fire, meaning the speed of the bullet, and therefore the distance traveled, would be reduced after the bullet deflected off a surface.

The 2010 Final EIS described an analysis conducted using a combination of Marine Corps and Army methodology to determine the probability of direct strikes to a marine mammal, which found a very low likelihood that a projectile would come in contact with a dolphin (0.08524 dolphins per year), with an even lower possibility of imparting significant injury to the animal. Should munitions land in the water, the rapid sinking rate of such munitions is expected to preclude ingestion by marine organisms.

Scoping comments for this SEIS noted concern regarding the possibility that contamination could migrate from the ranges through stormwater runoff. However, as discussed in Section 5.2.2, Water Resources, there would be no impacts to nearshore waters due to implementation of surface water protection measures (i.e., compliance with Construction General Permit requirements and implementation of BMPs during construction and implementation of LID, range maintenance BMPs, and pollution prevention plans during operations).

In addition, erosion control, sediment runoff control, and spent munitions containment strategies would be implemented, and munitions and residue from range construction or use would remain on ranges to be treated and managed. Such munitions and residue would be treated and managed according to applicable DoD Directives and UFC requirements, as well as other measures being considered by the DON (as described in a manual titled “Prevention of Lead Migration and Erosion from Small Arms Ranges” [NAVFAC Pacific EV24SH, personal communication, April 26, 2013]). As discussed in Section 5.5.2, Water Resources, there would be no impacts to nearshore waters through implementation of surface water protection measures (i.e., implementation of LID, range maintenance BMPs, and pollution prevention plans during operations).

**Marine Flora and Invertebrates**

There would be no in-water training. Given the very limited quantity of bullets that would be deflected or ricochet off the bermed areas with enough residual energy to enter the marine environment and the BMPs described above, no impacts are expected to occur to marine flora and invertebrates as a result of the operation of the proposed LFTRC at NWF.
Fish

As previously discussed under Marine Flora and Invertebrates, the nominal quantity of bullets that would overshoot the bermed areas to enter the marine environment and the implementation of BMPs described above would result in less than significant direct impacts to fish as a result of LFTRC operational activities.

Essential Fish Habitat

As previously discussed under Marine Flora and Invertebrates, the nominal quantity of bullets that would overshoot the bermed areas to enter the marine environment and implementation of the BMPs described above would result in less than significant direct impacts to EFH from LFTRC operational activities.

Per the MSA, there would be no adverse effect on EFH because the proposed action would not reduce the quality or quantity of EFH as a result of LFTRC operational activities.

In accordance with the Magnuson-Stevens Fishery Conservation and Management Act, the DON initiated informal consultation with the NOAA’s NMFS Pacific Islands Regional Office, Habitat Conservation Division in May 2014 to determine the potential effects of construction and operations of DON’s preferred alternatives (Alternatives E and 5) on EFH. NMFS reviewed the 2014 Draft SEIS on Guam and CNMI Military Relocation (2012 Roadmap Adjustments) and supplementary information provided by the DON during the course of the EFH consultation.

NMFS determined that adverse effects to EFH would occur unless recommended conservation measures were implemented. NMFS identified seven conservation recommendations to avoid and minimize impacts to EFH. The NMFS EFH effects determination letter of April 27, 2015 containing the complete list of recommendations and the DON’s response to the determination letter are located in Vol. 2 Appendix F.5. NMFS’ recommended conservation measures are summarized below.

- The DON should commit to ensure that the Northern Districe WWTP is upgraded to meet GWQS with an emphasis on orthophosphate, nitrate-nitrogen, and ammonia concentrations. The DON should encourage GWA to reduce nutrient levels even further as the GWQS are still above recommended levels of nitrate and orthophosphate discharges for coral reef habitats.
- The DON should, to the greatest extent practicable, minimize stormwater runoff and prevent increases in the amount of water discharged through freshwater seeps into nearshore coastal waters for each project component.
- The DON should further examine the fate of stormwater for these project components, particularly the Finegayan Cantonment and the NWF LFTRC, to determine whether stormwater practices affect sensitive nearshore reefs such as the HAPCs at Haputo ERA and the Ritidian Unit of the Guam NWR through seeps.
- The ROD should clearly identify funding and provide minimal guidelines for programs to minimize impacts from training, recreation, and fishing activities for Marine Corps personnel.
- Ensure that each Marine Corps unit assigned to Guam irrespective of duration and deployment status will institute a physical training awareness and operational guidance that identifies appropriate physical training areas as well as identify sensitive areas that are off-limits for such activities in coordination with installation and regional resource management plans.
- Develop methods to minimize fishing impacts by reducing take of fish species from key functional groups and rare species. This could include a ban for DoD personnel on use of destructive methods of fishing including for species of local concern such as humphead wrasse and green humphead parrotfish.
• The DON should provide a commitment to develop and implement a detailed and comprehensive Adaptive Management Plan that defines watershed management and erosion control mechanisms that will be adopted based on current best available information and involve a protocol articulating the framework to include assessing and mitigating cumulative impacts.

Special-Status Species

No explosive projectiles are proposed for use and all projectiles are expected to be contained within the range footprint by bullet traps or backstops, with the exception of ricochets, which would be contained within the SDZs, according to statistical analysis provided in the 2010 Final EIS. Signage as well as lighting (blinking red lights) would notify people in the area that the ranges are in use. However, the signage and lighting would be designed to insure minimal to negligible impacts on special-status species, primarily sea turtles. Therefore, there would be less than significant direct impacts to special-status species as a result of LFTRC operational activities.

On December 10, 2014, pursuant to section 7(a)(2) of the ESA, the DON requested informal consultation with NMFS Pacific Islands Regional Office regarding the effects of the proposed action on ESA-listed marine species: the threatened scalloped hammerhead shark and four species of threatened coral (Acropora globiceps, Acropora retusa, Pavona diffuens, and Seriatopora aculeata). Based on further consultation, the DON determined that only three of these recently listed species could occur in the vicinity of the proposed action and accordingly, the DON requested informal consultation to address potential effects to these newly listed species.

The DON requested informal consultation for two separate proposed action elements which may have the potential to affect either the scalloped hammerhead shark or the four species of threatened coral identified above:

• The effects of the projected increase of effluent from the Northern District WWTP outfall, a GWA facility.
• The effects of constructing the AVLA in Inner Apra Harbor.

The DON determined that the projected increase of effluent from the Northern District WWTP may affect, but is not likely to adversely affect Acropora globiceps, Acropora retusa, and Seriatopora aculeata, and the scalloped hammerhead shark because the effects are insignificant.

The AVLA includes a vehicle ramp which is the only in-water project not completed from the original 2010 EIS and associated ESA section 7 consultation with NMFS. The DON determined that the AVLA project may affect but is not likely to adversely affect the scalloped hammerhead shark because the effects are discountable.

At the request of NMFS, on April 13, 2015 the DON provided additional detailed information about the proposed action and potential conservation and mitigation measures (see Appendix F.5). Consultation with NMFS concluded with a letter of concurrence on May 18, 2015 (see Appendix F.5). NMFS considered the information in the DON’s EIS/OEIS (2010), the Draft SEIS (2014), and consultation requests, as well as the best scientific information available about the biology and expected behaviors of the ESA-listed marine species and agreed with the DON conclusion that the proposed action is not likely to adversely affect the scalloped hammerhead shark or the ESA-listed corals.

NMFS also agreed that the proposed action would have no effect on critical habitat. NMFS provided in their letter of concurrence five conservation recommendations that they deemed prudent. The DON will
consider adoption of one or more of these conservation recommendations and will address them in the ROD for this proposed action.

**Marine Conservation Areas**

Range utilization would depend on the number of personnel required to complete annual individual training events, the duration of each event, and the training capacity of each range, but range availability for DoD training would be approximately 39 weeks per year with 13 weeks of non-availability for DoD training per year for weather, maintenance, and holidays. Alternative 5 operational activities would result in less than significant direct and indirect impacts to conservation efforts and management activities at the Guam NWR - Ritidian Unit with the implementation of BMPs and coordination between USFWS and the DON for current or planned research and conservation programs.

### 5.5.10 Cultural Resources

#### 5.5.10.1 Affected Environment

The following discussion summarizes previous cultural resources studies, known historic properties, and other cultural resources within the PDIA and PIIA associated with Alternative 5. The Alternative 5 area, also known as the NWF alternative, is situated on the NWF section of AAFB and portions of the Ritidian Unit of the Guam NWR. The Ritidian Unit is owned and managed by the USFWS. Historically, portions of the area known as Tailalo underwent extensive development during and after WWII with the construction and use of NWF. The Ritidian area contains a substantial number of Pre-Contact and historic sites, with evidence of occupation potentially dating as early as 3500 years before present, as well as a Spanish mission, *latte* sites, and cave sites with pictographs (Carson 2012, 2014).

The affected environment for cultural resources associated with Alternative 5 is consistent with the affected environment description in the 2010 Final EIS (Volume 2, Chapter 12: Cultural Resources, Section 12.1.2.1: Andersen AFB, pages 12-9 to 12-16). This description of the affected environment is updated here with new information from recent archaeological and architectural investigations conducted for this SEIS and other projects. To determine whether site information is from previous investigations (such as the 2010 Final EIS or other cultural resource studies) or prepared during in-fill studies conducted for this SEIS, refer to dates in the reference column in each table for the archaeological sites.

Portions of the Alternative 5 PDIA and PIIA were investigated for the presence of cultural resources for the original proposed action (2010 Final EIS). Cultural resource investigations for the Final EIS and other previous investigations in the area included archaeological surveys (Grant *et al.* 2007; Church *et al.* 2009; Dixon and Walker 2011; Dixon *et al.* 2011b; Dixon *et al.* 2012), architectural inventories (Aaron *et al.* 2007), and TCP studies (Welch and Prasad 2006). Investigations at Ritidian have included intensive surveys (Dixon 2000) and excavations (Kurashina 1990; Olmo 1997; Bayman *et al.* 2010; Carson 2012, 2014; Jalandoni 2011). Additional investigations conducted for this SEIS included intensive cultural resource inventories in the PDIA and reconnaissance inventories in the PIIA (Dixon *et al.* 2015a, 2015b). Collectively, these investigations provide the comprehensive inventory of cultural resources for analysis in Alternative 5.

As described in Section 5.1.10.1, the HG Range would be located at Andersen South under all of the LFTRC alternatives. The entire area was previously surveyed at an intensive level (Welch 2010; Dixon *et al.* 2011a).

During October through December 2014, the DON consulted with the parties to the 2011 PA and the public on the Draft TRRA. Consistent with Stipulation V.C of the 2011 PA, the TRRA provided planning...
level information on potential direct and indirect effects to historic properties within areas that may be selected in the Navy’s ROD for the live-fire training range complex. The Draft TRRA included information on the locations, orientations, and designs of each proposed LFTRC location. In addition to receipt of written comments, DON cultural resources professionals conducted three consultation sessions with the parties to the PA to discuss the analysis. The DON will take all comments into account in preparing the Final TRRA, which is planned for publication shortly after this Final SEIS. Comments and considerations developed during the Draft TRRA consultation process have been incorporated in this Final SEIS and informed the Draft RMP, as required by Stipulation V.C.4 of the 2011 PA.

Cultural Resources in the Alternative 5 PDIA

Alternative 5 would involve the construction of individual ranges, support buildings, towers, access roads, and the relocation of the USFWS facilities at the Ritidian Unit of the Guam NWR. The PDIA consists of the limits of proposed construction.

Table 5.5.10-1 lists 35 known archaeological sites located within the Alternative 5 PDIA on AAFB and the Ritidian Unit of the Guam NWR. Twenty sites, including artifact and ceramic scatters, a rock alignment, a rock shelter, the Ritidian Site Complex, and NWF (a historic airfield) are eligible for listing in the NRHP.

Fifteen sites, consisting of disturbed Pre-Contact ceramic scatters and historic WWII sites, are not eligible for listing in the NRHP. Should this alternative be selected, archaeological sites that cannot be avoided would be evaluated following the procedures in the 2011 PA. No historic properties have been identified in the PDIA for the proposed HG Range at Andersen South.

Legend: GHPI = Guam Historic Properties Inventory; NRHP = National Register of Historic Places; NA = not applicable. NRHP criterion D = eligible for potential to yield information important in prehistory or history.

Notes: ¹Not all sites recorded within the project areas have received official GHPI numbers, although they have been documented as part of previous surveys.
²Sites are in both the PDIA and the PIIA.
**Revised to match Guam GHPI forms dated May 28, 2014.
***The Guam SHPO concurs with this recommendation (Guam SHPO correspondence dated August 12, 2014 [RC2013-0904]).

No TCPs have been identified in the PDIA for this alternative (Welch and Prasad 2006; Griffin et al. 2010).

Cultural Resources in the Alternative 5 PIIA

The PIIA consists of the area within the SDZs for the LFTRC and HG ranges and associated areas potentially affected by increases in noise. Table 5.5.10-2 summarizes the 79 known archaeological sites located within the Alternative 5 PIIA. There are 60 known NRHP-eligible sites in this area, including the Ritidian Site Complexes (GHPI Numbers 66-08-0012 and 66-08-0013), a portion of the Jinapsan site (GHPI number 66-08-0014), artifact scatters, NWF, and rockshelters. One of the Ritidian Site Complexes is also located within the PDIA. The remaining 19 sites, which include a WWII-era fuel tank farm and a historic site with concrete foundations and a cobble retaining wall, are not eligible for listing in the NRHP. Three structures associated with the FWS are located within the PIIA. None of these structures are eligible for listing in the NRHP. No TCPs have been identified in the PIIA for Alternative 5. Natural resources of cultural importance may occur in this area.

5.5.10.2 Environmental Consequences

**Construction**

Construction activities associated with Alternative 5 may adversely affect historic properties and impact culturally important natural resources. Final determinations of effect would follow the procedures in the 2011 PA. Following is a discussion of potential direct and indirect adverse effects to historic properties and impacts to culturally important natural resources.
Construction of the ranges, support facilities, utilities, and road construction would primarily occur in the NWF area of AAFB (see Figure 2.5-6). However, the construction of an access road and a vehicle access gate would occur on the Ritidian Unit of the Guam NWR and could adversely affect site 66-08-0012. Given the substantial development anticipated in the PDIA, it is assumed for purposes of this analysis that 100% of the area would be disturbed. Nevertheless, design alternatives to avoid and minimize adverse effects would be considered, consistent with procedures in the 2011 PA. No construction is proposed in the PIIA. Excavation and soil removal associated with the construction of Alternative 5 could adversely affect 20 known historic properties, including Pre-Contact artifact scatters and sites containing latte components (see Table 5.5.10-1). Fourteen of the historic properties are located within both the PDIA and the PIIA. Direct impacts to these sites would only occur to the portion within the PDIA.

Under Alternative 5, the Guam NWR administrative offices would be relocated to the southwest. The existing Guam NWR buildings, which are not considered eligible for listing in the NRHP, would be left in place.

Construction activities associated with Alternative 5 have the potential to directly impact culturally important natural resources. The project would require the removal of limestone forest where culturally important natural resources, including traditional plants, may be present. The 2011 PA contains measures for coordinating with the SHPO and concurring parties to contact traditional natural healers, herbal practitioners and traditional artisans regarding identification and disposition of these important resources prior to construction (see 2010 Final EIS, Volume 2: 2-10; Volume 9, Appendix G, Chapter 4).

No historic properties or culturally important natural resources are anticipated in conjunction with utility upgrades that would be associated with Alternative 5. The modification or replacement of existing overhead electrical lines under Alternative 5 would not affect any known cultural resources. Water and wastewater utilities would be placed along Perimeter Road and on a new access road. There are no known NRHP-eligible sites or structures located in the areas planned for water or wastewater utility upgrades. No adverse effects to historic properties are anticipated in conjunction with these utility upgrades.

There are no historic properties located in the PDIA or the PIIA for the proposed HG Range at Andersen South. Therefore, no adverse effects to historic properties are anticipated due to construction of the HG Range.

Operation

Operations associated with Alternative 5 could cause indirect adverse effects to historic properties as discussed below. Final determinations of effect would follow the procedures in the 2011 PA. Following is a discussion of potential adverse effects of operations associated with Alternative 5.

The potential for direct effects within the SDZ would be limited to the risk of strikes from stray rounds during Alternative 5 operations. The risk of such effects occurring is extremely low. The range would be designed to contain live fire inside the range itself to minimize the probability of rounds landing in the SDZ. The natural terrain would also serve to prevent direct effects in the SDZ, because the culturally sensitive areas within the Alternative 5 SDZs are substantially lower in elevation than the site of the range. Additionally, if a stray round were to escape the range, the chance of it hitting a historic property is remote, given the size of the SDZ and dispersal of historic properties. For these reasons, the potential for direct adverse effects as a result of range operations is de minimis.

Indirect adverse effects to NRHP-eligible archaeological sites from the operation of Alternative 5 could result from changes affecting site integrity. For many types of archaeological sites (e.g., ceramic scatters, rock alignments), auditory impacts associated with live-fire operations would not affect characteristics.
that qualify them for the NRHP. An increase in noise associated with live-fire operations may adversely affect historic properties for which solitude, quiet, or contemplation contribute to or define their significance, such as TCPs.

Areas near the ranges are currently subject to intermittent noise from aircraft up to 60 dB DNL, although most areas currently have average noise levels of less than 60 dB DNL (see Section 5.5.4, Noise). Under Alternative 5, small arms live-fire noise would be audible near 46 NRHP-eligible sites that are located within the expanded noise contours (Table 5.5.10-3). Average noise levels during range operations are projected to increase from current levels of less than 60 dB to between 65 dB and 85 dB ADNL due to the introduction of small arms live-fire noise. At the Ritidian Unit of the Guam NWR, noise levels are projected to increase from current levels of less than 60 dB to over 80 dB ADNL in some areas, although some attenuation below the cliffline is expected due to topography. Forty-two NRHP-eligible sites are Pre-Contact artifact scatters, rockshelters, historic military sites, and a portion of NWF (66-08-1065). Three NRHP-eligible sites have multiple latte components and one NRHP-eligible site is a cave site.

</tbody>
</table>

Legend: NRHP = National Register of Historic Places; NA = not applicable; NRHP criterion D = eligible for potential to yield information important in prehistory or history.

Note: ** Revised to match Guam GHPI forms dated May 28, 2014.

Based on the analysis, changes in the setting would not indirectly adversely affect the integrity of 43 NRHP-eligible artifact scatters, rockshelters, or historic military sites. However, three potentially noise-sensitive NRHP-eligible sites with latte components and cave sites with pictographs could be indirectly adversely affected by substantial changes in the audible environment. Final determinations of effect would follow the procedures in the 2011 PA.

As indicated in Section 5.5.11, indirect adverse effects from visual intrusions associated with Alternative 5 would be minimal as the ranges are within an existing military operations area and the action would not involve a change in visual setting.

Access within the SDZs would be restricted during range operations. Cultural sites located on AAFB currently have limited access due to operations. Portions of the Ritidian Unit of the Guam NWR are currently open to the public. Portions of two NRHP-eligible archaeological sites, the Ritidian Site Complexes (66-08-0012 and 66-08-0013), are located within the SDZs that overlay portions of the Ritidian Unit. Portions of these sites are accessible to the public through tours and public education programs and are part of on-going scientific research programs. Under Alternative 5, access to these sites would be restricted while the ranges are in use. Access to these sites during those periods when the ranges are not in use is a matter under the management authority of the USFWS. Restricted access associated with operation of Alternative 5 would be a significant impact.
Summary of Impacts and Potential Mitigation Measures

Implementation of Alternative 5 could cause direct adverse effects to 20 known NRHP-eligible archaeological sites. Potential indirect adverse effects could occur to three NRHP-eligible archaeological sites. Potential impacts could also occur to two NRHP-eligible sites (GHPI Numbers 66-08-0012 and 66-08-0013), as a result of reduced access. In addition, culturally important natural resources could be directly impacted due to removal of limestone forest. Under this alternative, there would be more adverse effects from construction at NWF than any of the other LFTRC alternatives. There would be more adverse effects from operations under Alternative 5 than under any of the other alternatives. Refer to Section 5.7, Table 5.7-1 for a comparison of cultural resources impacts and potential mitigation measures for each LFTRC alternative.

The 2011 PA, as discussed in Section 3.1.2, establishes a program alternative for complying with NHPA Section 106 requirements. Broadly, the 2011 PA includes processes to share information, consider views of the public, and develop mitigation measures when historic properties may be adversely affected. The 2011 PA provides measures for mitigating adverse effects to NRHP-eligible or listed archaeological sites, consulting on new projects and initiating additional identification efforts, and resolving impacts due to loss of access to potential TCPs or culturally important natural resources.

More specifically, the 2011 PA established a process for the review and analysis of potential effects to historic properties and other cultural resources for all alternative LFTRC locations. During October through December 2014, the DON consulted with the parties to the PA and the public on the TRRA, which provided information about cultural resources potentially affected by the LFTRC alternatives carried forward in the SEIS, consistent with PA Stipulation V.C. The TRRA provides information on potential adverse effects resulting from the construction and operation of the LFTRC alternative to support consultation with the PA parties and the public. The DON will take all comments into account before reaching a final decision. For any alternative selected in the ROD, the 2011 PA stipulates that a RMP will be prepared to address effects from the construction and operation of the ranges. The RMP, developed in consultation with the consulting parties, will stipulate measures to avoid, minimize, and mitigate adverse effects to historic properties.

To the degree possible, impacts to historic properties and natural resources of cultural importance would be avoided or minimized during the planning process. Consultation under the 2011 PA would address potential adverse effects and alternatives to avoid adverse effects. Refer to Section 3.10 for more information on definitions and procedures. If avoidance is not possible, Table 5.5.10-4 presents potential mitigation measures to resolve adverse effects to historic properties and reduce impacts to cultural resources resulting from the implementation of Alternative 5. With the implementation of these measures and processes as outlined in the 2011 PA, it is expected that direct and indirect, short- and long-term impacts would be reduced to a level below significance in all but one instance. Loss of access to the Ritidian Site Complexes, as they are currently accessible to the public daily, would remain a significant impact under NEPA with reduced accessibility by the public. The DON would pursue an agreement with USFWS in accordance with the provisions of Section 2822 of the FY 2015 NDAA, which would allow for the continued management of the Ritidian Unit consistent with the purposes for which it was established and the operation of the range SDZs associated with the LFTRC preferred alternative at NWF. The DON anticipates that access restrictions will be addressed in this agreement.

5.5.11 Visual Resources

5.5.11.1 Affected Environment

A list and description of visual resources at NWF are provided in the 2010 Final EIS (Volume 2, Chapter 13: Visual Resources, Section 13.1.1.1: Andersen AFB, pages 13-1 to 13-8). NWF, located in the northwestern sector of AAFB, contains several old runways within a setting of dense tropical vegetation. The landscape is heavily vegetated, dominated by wide-canopy trees and shrubs that generally block long-distance views. Along the adjacent coastline lie several scenic points of interest that provide recognized scenic and recreational value, such as Ritidian Point and Uruno Point. The views at Ritidian Point and Uruno Point are discussed in the 2010 Final EIS (Volume 2, Chapter 13: Section 13.1: Affected Environment, Section 13.1.1.3, Andersen AFB, page 13-15). Photo 5.5.11-1 shows the view of Alternative 5 from Route 3A.

Photo 5.5.11-1: View of Route 3A descending to the Guam NWR Nature Center at Ritidian Point-NWF (View of Alternative 5 location in the upper-half of the photo)

Source: AECOM 2010c
5.5.11.2 Environmental Consequences

Construction

During construction, activities and equipment would temporarily cause view obstructions where recognized views currently exist. The short-term direct visual impacts during the construction phase would be less than significant.

Operation

As discussed in the 2010 Final EIS (Volume 2, Chapter 13: Visual Resources, Section 13.2.2.1: North, pages 13-262 to 13-267), development of land adjacent to Route 3A for a live-fire training range would result in minor alteration of the existing visual landscape. Although Route 3A is accessible to the public, the surrounding land is federal property and is closed to the public. Accessible views into these areas are limited because of the relatively flat topography of the plateau and substantial vegetation along the roadway. The affected areas are mostly grass and are adjacent to the NWF airfield. The Ritidian Point overlook located immediately adjacent to Route 3A before the road begins its descent along the cliff slopes is at a lower elevation than the nearby development at NWF and the views from this area would not be affected by development. Because of the amount of clearing and development for Alternative 5, as well as the lack of publicly accessible views into the area, the long-term direct impact on visual resources would be less than significant.

Alternative 5 would have less of an impact to visual resources than Alternatives 1, 3, and 4, and a similar level of impact compared to Alternative 2.

5.5.12 Ground Transportation

5.5.12.1 Affected Environment

The affected environment for ground transportation resources associated with the Alternative 5 includes transportation facilities internal to the site (range roadways and intersections). This section discusses existing conditions and assesses how construction and operations of Alternative 5 would potentially affect transportation conditions for roadways and intersections internal to the site. Impacts to off-base (external) roadways and intersections are summarized in Section 6.1 of this SEIS.

5.5.12.2 Environmental Consequences

Construction

Potential construction impacts to ground transportation under Alternative 5 would be the same as those discussed in Section 4.2.12.2 for Alternative A. Potential direct and indirect impacts to ground transportation resources from construction would be minimized with implementation of appropriate work zone traffic management strategies and BMPs. Therefore, there would be less than significant short-term impacts to on-base (internal) roadways.

Operation

Proposed entry to Alternative 5 would be via Route 3A. The existing roadway and gate area would be improved to support LFTRC traffic and an Entry Control Facility would be constructed to control access during hours of operation. Secondary access would be provided on existing roads in the NWF complex. Approximately 5 miles (8 km) of roads would be improved or constructed to support LFTRC traffic. Potential operational impacts for Alternative 5 would be the same as those described in Section 5.1.12.2 for Alternative 1; and there would be no direct, long-term significant impacts to internal (range) roadway segments or intersections.
5.5.13 Marine Transportation

5.5.13.1 Affected Environment

The location and orientation of Alternative 5 would result in an SDZ that encompasses an area of approximately 3,059 acres (1,238 ha) of the Philippine Sea off the northern coast of Guam. In addition, the Alternative 5 SDZ would encroach on a designated shipping lane used by all vessels traveling directly from Hawaii to Guam. The encroachment would obstruct a near-shore portion of the lane, extending approximately 2 miles (3 km) from the shoreline.

5.5.13.2 Environmental Consequences

The area of the SDZ will be closed to all vessel traffic on an intermittent basis, following 33 CFR 334, to allow uninterrupted training. The temporary nature of the closure and the location of the SDZ minimal distance from the shoreline would result in a less than significant impact on marine transportation.

In order to ensure that vessels are not at risk of accidentally entering the SDZ and being struck by projectiles from the firing ranges, designated military personnel, trained in the use of sighting equipment, would observe the SDZ and nearby waters for vessel traffic. Two proposed Range Observation Towers would give observers an unobstructed view to survey the SDZ for vessels before and during live-fire exercises. Live-fire training would cease if a vessel entered the SDZ and resume only when the SDZ was cleared. Cessation of live fire via observer notice would mitigate the risk of a vessel being struck by projectiles. The SDZ area would be identified on nautical charts, but will not be physically marked on the ocean surface. Standard operating procedures would be implemented to notify mariners of training activities and ensure that the SDZ is cleared of vessels prior to live-fire training.

An aid to navigation at Ritidian Point (Figure 5.5.6-1) is within the resulting SDZ of Alternative 5; however, there is a low risk of impact from projectiles from the LFTRC due to the angle from the range orientation. The aid to navigation would be to the west of the range control tower.

5.5.14 Utilities

5.5.14.1 Affected Environment

Existing utilities in the vicinity of the proposed HG Range are the same as discussed in Section 5.1.14.1 for Alternative 1.

Electrical Power

The electrical utility near the proposed Alternative 5 consists of the existing local DoD 3-phase 13.8 kV overhead power distribution system serving the NWF, including the Rapid Engineer Deployable Heavy Operational Repair Squadron Engineers facilities and existing USFWS facilities.

Potable Water

The potable water system near Alternative 5 includes elements of the DoD water transmission and distribution system. This existing functioning system consists of underground water lines and manholes serving the Rapid Engineer Deployable Heavy Operational Repair Squadron Engineers facilities at NWF, which is supplied by existing Well AF-5. The DoD water distribution system is typically 8-inch (20-cm) diameter buried pipe.

The existing USFWS facilities utilize a water catchment system with an on-site treatment system, supplemented with water tank trucks, as needed.
Wastewater

The wastewater utility near Alternative 5 consists of a buried wastewater collection system serving the Rapid Engineer Deployable Heavy Operational Repair Squadron Engineers facilities on AAFB. This system has an 8-inch (20-cm) diameter sewer along Perimeter Road. There is currently no wastewater collection system in the immediate vicinity of this alternative.

The existing USFWS facilities currently utilize septic tanks with leachfield systems.

Solid Waste

There are no solid waste facilities near Alternative 5.

Information Technology and Communications

There is no DoD IT/COMM infrastructure in the immediate vicinity of LFTRC Alternative 5.

5.5.14.2 Environmental Consequences

Electrical Power

The proposed electrical system improvements for Alternative 5, as described in Sections 2.5.4.5 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The long-term electrical power requirements of the LFTRC facilities would be small (less than 50 kW), and thus have minimal direct impact on the current system or current power customers. During construction, current users could experience short-term minimal power outages. With careful planning, these potential outages would be minimized.

The short- and long-term, direct impact of Alternative 5 on the electrical utility would be less than significant, during both construction and in operation.

Potable Water

The proposed water system improvements for Alternative 5, as described in Sections 2.5.4.5 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The Range Maintenance Building and the KD Rifle/KD Pistol Range Administrative Building are the only LFTRC facilities requiring water service. A fire hydrant would also be provided for filling range fire fighting vehicles and general fire protection. The proposed LFTRC water supply would serve the Range Maintenance Building and the KD Rifle/KD Pistol Range Administrative Building. The long-term potable water demand of the LFTRC would be small, estimated at an average daily demand of 26,520 gallons per day (100,389 liters per day). Therefore, less than significant long-term direct impact would occur to the current DoD system. The relocated USFWS facilities would continue to receive potable water from their catchment and on-site treatment system. There would be no impact on the potable water resource from relocation of the USFWS facilities. During construction, short-term, minor water service outages. With careful planning, these potential outages would be minimized.

The short- and long-term, direct impact from LFTRC Alternative 5 to the potable water utility would be less than significant, both during construction and operations.

Wastewater

The proposed wastewater collection system improvements for Alternative 5, as described in Sections 2.5.4.5 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The only LFTRC facility requiring sewer service would be the Range Maintenance Building and the KD Rifle/KD Pistol Range Administrative Building, that have an estimated wastewater
flow of less than 0.01 MGd (0.038 MLd). Due to the remote location and low volume of wastewater flow, the wastewater system would consist of gravity sewer line, septic tank, and effluent disposal basin. Design of septic tank would be in accordance with GEPA Toilet Facilities and Sewage Disposal Guidelines. Design of an effluent disposal basin would be in accordance with Manual for Constructed Wetland and Aquatic Plant Systems for Municipal Wastewater Treatment, and be acceptable to GEPA. The design would be similar to alternative sewer design used in the North Gate project. The sewage would be designed to pass from the buildings into septic tanks where it would be pumped into a self-contained effluent disposal facility. The liner would be designed to keep the effluent from entering groundwater and to keep the rainwater from flooding the field and washing the effluent into the environment. Three layers of material, course rock, sand, and soil would be contained within the disposal area. The soil and sand would be designed to create a growing environment for the plants. The rock would be designed to be a conveyance system for the effluent to spread through the area of the facility. The long-term estimated wastewater demand for these facilities is small and there would be no direct impact on the existing sewer collection or treatment systems.

All other LFTRC facilities, including the HG Range, would be provided with portable toilets. These toilets would require periodic emptying, with the sewage taken to one of the existing WWTPs for treatment. The estimated sewage amount is minimal and would not have a long-term, direct impact on the current wastewater resource.

The relocated USFWS facilities could be serviced for wastewater by three options: (1) a sewer line with a surge holding tank (in case of power outage) and a series of five pump stations to overcome the large elevation difference between the facilities, as well as the existing sewer line servicing the Rapid Engineer Deployable Heavy Operational Repair Squadron Engineers facilities, (2) a holding tank requiring periodic emptying with the wastewater being taken to the North District WWTP, or (3) a new septic tank constructed adjacent to the relocated facilities. Option 3 was ruled out due to concerns regarding impact to the NGLA. Option 1 or 2 are viable, with Option 2 having a reduced estimated capital cost. With either Option 1 or 2, the estimated wastewater flow from the USFWS facilities is small and would have only a minimal long-term, direct impact on the current sewer system by slightly increasing the amount of flow.

Any outages to service during construction would be short-term and minimal by doing tie-in work at low flow times, providing bypass lines and pumps, and by careful planning and design of the tie-in methods.

The current wastewater systems planned to be utilized by LFTRC Alternative 5 would be impacted minimally by this proposed action. Thus, the short- and long-term, direct impact from LFTRC Alternative 5 to the wastewater utility would be less than significant during both construction and operations.

Solid Waste

The proposed solid waste infrastructure improvements for Alternative 5, as described in Sections 2.5.4.5 and 2.5.4.6 (for HG Range), have been developed to meet the requirements for the proposed action. The estimated solid waste generation for LFTRC operations is small and this long-term additional solid waste would not directly impact current waste collection, handling, or disposal operations. Suitable solid waste collection containers would be provided where required. The solid waste would be periodically collected, handled, and disposed by contractors or DoD personnel already serving the NWF.
There would be a short-term, direct impact to the solid waste handling effort during the U&SI construction, involving the generation of green waste following the clearing and grubbing of the range areas and roads, as well as generation of C&D debris waste during construction. The U&SI contractor would be required to process the generated green waste as part of their assigned contract requiring 100% diversion of the green waste into mulch (trees and stumps) and compost (leaves and grass), and 60% minimum diversion of C&D debris waste. The DON subject matter experts will review the U&SI's contractor's green waste processing and composting facility operations plan to ensure that it meets industry and regulatory standards. The U&SI contractor will be responsible for obtaining the solid waste facility permit issued by GEPA prior to commencing activities.

The C&D debris and green wastes that cannot be recycled or reused, as well as wastes that are prohibited at Layon Landfill would be disposed at the Naval Base Guam Landfill, subject to ongoing discussions between the DON, USEPA, and GEPA, and permitted private hardfill facilities. The DON proposes to explore ways to resolve key solid waste issues, specifically the status of the Naval Base Guam Landfill permit and handling of special wastes not accepted at Layon Landfill, through the Solid Waste Working Group that was established with USEPA and GEPA on July 24, 2014. During the September 19, 2014 meeting of the Solid Waste Working Group, GEPA indicated that they will formally respond to DON correspondence with regards to issues relative to the Naval Base Guam Landfill. The Layon Landfill and the permitted private hardfill facilities are operating within their regulatory requirements. The proposed action would be in compliance with all applicable GEPA solid waste permit terms and conditions that routinely include specific measures to protect human health and the environment. All other projects on Guam would utilize permitted solid waste management and disposal facilities.

The short- and long-term, direct impact of Alternative 5 on the solid waste facilities would be less than significant, during both construction and operations.

Information Technology and Communications

The proposed IT/COMM infrastructure improvements for Alternative 5 as described in Section 2.6 have been developed to meet the requirements for the proposed action. Since there are no existing IT/COMM resources in the immediate vicinity of this LFTRC alternative, there would be no direct, long-term impact on existing IT/COMM services. Alternative 5 would require installation of new conduit duct banks consisting of six 4-inch (10-cm) conduits for interconnecting the LFTRC range facilities, including the HG Range. There would also be inter-base connectivity required for DoD IT/COMM, as discussed in Section 2.6. Installation of these IT/COMM lines could cause short-term, temporary service disruptions to current IT/COMM users. With careful planning, these potential disruptions would be minimized.

The short- and long-term, direct impact of Alternative 5 to the IT/COMM utility would be less than significant during both construction and operation.

5.5.15 Socioeconomics and General Services

5.5.15.1 Affected Environment

Most issues and impacts associated with socioeconomics and general services encompass the entire proposed action (i.e., cantonment/family housing and LFTRC development, increased population), and do not vary with site alternatives. Accordingly, the impact discussion in Section 4.1.15 of this SEIS applies for all of the LFTRC alternatives and is incorporated here by reference. Land acquisition, however, is unique to the LFTRC alternatives, and the amount of land to be acquired varies by alternative. Therefore, this section focuses exclusively on the socioeconomic and sociocultural issues and impacts associated
with the acquisition of land under Alternative 5 (with the exception of the HG Range, which would not require land acquisition).

5.5.15.2 Environmental Consequences

Sociocultural Impacts

Sociocultural impacts associated with land acquisition are less tangible and are conceptual frameworks such as social disarticulation and cultural marginalization (the deterioration of social structures, networks, or belief systems), and social and psychological marginalization, stress, and anxiety (a person’s loss of confidence in society and themselves, feelings of injustice, and reduced social status). See Appendix D, Section 5.2.2 for more detail.

Alternative 5 would not require federal land acquisition. Custody and control of 268 acres (108.5 ha) would be reassigned from DOI to DoD, and some areas that are currently accessible to the public would become restricted access areas. New restrictions on public access to the land and submerged lands encumbered by the NWF LFTRC could have long-term indirect adverse sociocultural impacts due to the potential that access restrictions to subsistence fishing and recreation areas would deteriorate social networks (i.e., if groups of people currently [or traditionally] use areas that would be restricted to hold social gatherings, then the access restrictions could impact those groups by deteriorating the social networks inherent in those groups). Also, as social networks may deteriorate due to the access restrictions, feelings of injustice may arise. While there is potential for social networks to deteriorate, it is not a certainty. Given the presence of other public recreation areas nearby, potential impacts are determined to be less than significant.

5.5.16 Hazardous Materials and Waste

5.5.16.1 Affected Environment

The current DoD ROI on Guam for hazardous materials and waste in this section includes the Air Force property proposed for development of the LFTRC. Air Force property includes the northern portion of NWF.

Hazardous Material and Hazardous Waste Management

The affected environment or present conditions at NWF with regards to hazardous materials and hazardous waste management would be the same as described in Section 3.16.1 of this SEIS, which provides a summary of hazardous materials, hazardous waste, toxic substances, and contaminated site information pertinent to Guam. No hazardous materials storage or hazardous waste accumulation areas are located in the area of NWF proposed for development of the LFTRC.

Contaminated Sites

Installation Restoration Program Sites

There are two IRP and five potentially contaminated sites located in the area of NWF proposed for development for this LFTRC alternative. Only two of these sites are currently active and are depicted in Figure 5.5.16-1. The seven IRP and AOC sites are listed in Table 5.5.16-1 and described in the 2010 Final EIS (Volume 9, Appendix G: EIS Resource Technical Appendix, Chapter 3: Hazardous Materials and Waste Resources, Table 3.6-1 Summary of Active Navy Environmental Restoration Sites on AAFB, pages G-3-28 to G-3-37 and Table 3.6-22 Summary of Applicable SWMUs and AOC Sites on AAFB, pages G-3-38 to G-3-43).

In addition to these sites, there is one IRP site and seven AOCs within 0.25 mile (0.4 km) of the area of NWF proposed for development for this LFTRC alternative (Figure 5.5.16-1). These sites are listed in Table 5.5.16-1 and described in the 2010 Final EIS (Volume 9, Appendix G: EIS Resource Technical Appendix, Chapter 3: Hazardous Materials and Waste Resources, Table 3.6-1 Summary of Active Navy Environmental Restoration Sites on AAFB, pages G-3-28 to G-3-37 and Table 3.6-6 Summary of Applicable SWMUs and AOC Sites on AAFB, pages G-3-38 to G-3-43).

Toxic Substances Management

The proposed project area under this alternative is largely undeveloped. However, a few structures are located in the area that may be affected by the proposed development of an LFTRC. Any structure constructed prior to 1978 may contain LBP, ACM and PCBs.

According to USEPA, the parcel is located in an area classified as Zone 1 for Radon, indicating average indoor radon levels of greater than 4 pCi/L.

5.5.16.2 Environmental Consequences

Impacts to hazardous materials, hazardous waste and toxic substances under this alternative would be the same as those described under Section 5.1.16.2 of this SEIS. As described in Section 5.1.16.2, should there be a need to import off-island earthen materials, all GEPA, Department of Agriculture, and local rules and regulations would be followed. Therefore, implementation of Alternative 5 would result in less than significant direct or indirect impacts.
Construction

Contaminated Sites

There are contaminated sites undergoing characterization and/or restoration under various DoD environmental programs located within or in close proximity to the proposed construction areas under this alternative. Consideration and careful attention during project design phases must be given prior to construction to avoid overlap with these sites. If relocation of proposed construction projects that may overlap these contaminated sites is not possible, then various BMPs and construction operational protocol must be followed to protect human health and the environment. Adherence to applicable BMPs would reduce the likelihood and volume of direct accidental releases from site disturbance and enable timely implementation of cleanup measures, thereby minimizing potential direct or indirect impacts to the environment. In addition, special design techniques and methodology would be required to ensure the long-term structural integrity of proposed construction projects.

Installation Restoration Program Sites

All of the IRP sites that require no further action have been subject to health risk evaluations that have determined that these sites do not pose a public health risk as noted in the 2010 Final EIS (Volume 9, Appendix G, Section 3.6, Table 3.6-2, page G-3-39 and G-3-40). Development within or in the vicinity of these sites would be conducted in a manner protective of worker health and safety and in accordance with any land use controls that may have been placed on the sites.

Currently active sites would be subject to site specific investigations and remedial actions in accordance with Comprehensive Environmental Response Compensation and Liability Act as outlined in the facility Site Management Plan (2009) prior to construction activities. Contaminants of concern include antimony at Site 50 and aluminum and chromium and Site 52. Therefore, less than significant direct or indirect impacts would occur.

Military Munitions Response Program Sites

Active MMRP sites would be subject to a Comprehensive Site Evaluation process to fulfill the requirements of a Comprehensive Environmental Response Compensation and Liability Act Preliminary Assessment and Site Investigation prior to construction activities. UXO, MC and MEC, if present, would be removed from the MMRP sites as well as any contaminants of concern such as metals or explosives residues and disposed of in accordance with applicable federal and local regulations. Therefore, less than significant direct or indirect impacts would occur.

Operation

Hazardous Materials

Live-fire training ranges would generate a long-term increase in the release of hazardous materials from expended training materials resulting from proposed new training operations, and the impacts would be similar to those described in Section 5.1.16.2 of this SEIS. As described in Section 5.1.16.2, direct or indirect impacts would be less than significant.

Contaminated Sites

Contaminated sites (IRP and MMRP) identified under this alternative have been investigated and determined to pose no risk to human health or environmental receptors or would be investigated and remediated prior to facility construction to ensure than no health hazards would be present during site
operations. Therefore, the impacts to IRP/MMRP sites under this alternative would be less than significant.

5.5.17 Public Health and Safety

5.5.17.1 Affected Environment

Operational Safety

To protect the general public from intentional or accidental entry onto the NWF at AAFB, locked or manned gates are used where vehicles access is provided and a series of warning signs cautioning unauthorized personnel not to enter the area are posted along the perimeter of the installation. Unauthorized personnel are not allowed on the installation at any time.

The AAFB MSA is situated near NWF. Explosives handling and storage is the primary function of the AAFB MSA. Facilities within the MSA and the other areas within NWF that handle munitions have associated ESQD arcs that restrict the construction of inhabited buildings and other non-munitions related activities to minimize potential impacts on personnel and the general public from an explosive mishap.

Environmental Health Effects

Noise

Noise sources in and around NWF include surface traffic and other ground-training activities. Currently, the NWF south runway is used for fixed-wing aircraft operations and airborne operations, which include airdrop operations at a drop zone on the eastern end of the runway. The north runway is used for helicopter practice landings and airdrop operations at a drop zone on the eastern end of the runway. However, mission activities are scheduled to be moved. The North Runway would be the primary landing zone as well as the location for the drop zone, which would be moved more than 1 mile (1.6 km) southwest of its current location. Aircraft operations and ground-training activities at NWF are infrequent. Noise modeling for these operations has not been performed as there are fewer than 10 jet or 25 propeller-driven aircraft operations per day and noise contours are not anticipated to extend beyond the installation boundary. Details regarding current noise conditions at NWF are provided in Section 5.5.4.1.

Water Quality

Several water wells are situated within the NWF. Well AF-5 currently services the NWF. In addition, 11 new wells are planned for installation in this general area of AAFB. These wells each have a mandated 1,000-foot (305-m) buffer identified as a wellhead protection zone. Within this zone, future activities and development are restricted to ensure that contaminants are not introduced in these areas to protect the integrity of the island’s freshwater aquifers. Guam’s freshwater aquifers are susceptible to contamination from surface activities. GEPA requires treatment to ensure water quality meets safe drinking water standards. Section 5.5.2.1 provides details regarding current quality of potable water sources.

Hazardous Substances

The IRP focuses on cleaning up releases of hazardous substances that pose risks to the general public and/or the environment. The MMRP focuses on identifying and removing MEC. Nine AOC sites are situated within the area of NWF where the Alternative 5 development is proposed. These sites include AOCs 85, 86, 87, 89, 90, 91, 92, 93, and 94 (DON 2010b). Based on health risk evaluations, no further action has been recommended for AOCs 86, 87, 89, 90, and 92. A ROD has been prepared for AOCs 85 and 93 for soil excavation and removal. These sites have not yet been closed. AOCs 91 (UXO 4A) and 94 (UXO 6A) are both MMRP sites that are situated within the proposed MPMG live-fire training area.
For AOC 91, soil remedial or removal action has been recommended. For AOC 94, further investigation has been recommended to characterize the existence of UXO contamination or its potential for a release to the environment. The hazardous materials and waste section of this SEIS (see Section 5.5.16) provides additional detail about the status of AOC and MMRP sites.

**Unexploded Ordnance**

NWF is known to have a high probability for MEC as a result of the occupation by Japanese forces during WWII and subsequent assault by Allied/American forces to retake the island (DON 2012).

**Traffic Incidents**

No high crash frequency locations have been identified in the vicinity of Alternative 5.

### 5.5.17.2 Environmental Consequences

Potential impacts on public health and safety from implementation of Alternative 5 would be similar to those discussed under Alternative 1 (see Section 5.1.17).

**Operational Safety**

**Construction Safety**

Potential impacts from construction safety would be similar to those discussed for Alternative 1. During construction activities, a health and safety program would be implemented by the construction contractors based on industry standards for accident and pollutant release prevention. Because a health and safety program would be implemented for construction activities and the general public would be excluded from entering construction areas, potential short-term construction impacts on public health and safety would not result in any greater safety risk. Therefore, no direct or indirect impact on public health and safety related to construction activities is anticipated.

**Operation/Range Safety**

To protect the general public from intentional or accidental entry onto live-fire training ranges, a series of warning signs cautioning unauthorized personnel not to enter the area would be posted along the perimeter of the installation, as well as at the range area. Unauthorized personnel would not be allowed on the installation or range at any time. Civilian watercraft may inadvertently enter portions of the SDZ that extend over nearshore waters. Two Range Observation Towers would be erected to provide surveillance of the nearshore SDZ. Live-fire training would cease if the SDZ is penetrated by watercraft and would resume once the watercraft clears the SDZ.

SOPs require that before conducting training activities, the general public and non-participating personnel would be cleared from the area so that the only public health and safety issue would be if a training event exceeded the safety area boundaries. Risks to public health and safety would be reduced by confirming that the training area is clear. The Range Safety Officer would ensure that hazardous areas are clear of personnel during training activities. After a live-fire event, the participating unit would ensure that weapons are safe and clear of live rounds.

The position of the SDZs overlays the existing USFWS Ritidian Unit Administration Building and Visitors Center. As part of Alternative 5 development, these facilities would be relocated outside the SDZ footprint and general public access to a portion of the Wildlife Unit area would be reduced, to eliminate this conflict.
Possible interactions between training activities within nearshore areas would be minimized by ensuring that the area is cleared. Recreational diving activities within nearshore areas take place primarily at known diving sites, and dive boats typically are well marked with diver down flags. The Marine Corps also may notify the general public about training activities through Notices to Airmen and Notices to Mariners.

Public notification of training activities, use of established training areas, compliance with appropriate range safety procedures, and relocation of non-participating facilities would reduce the potential for interaction between the general public and personnel that are training. Specific and documented procedures would be in place to ensure the general public is not endangered by training activities. Therefore, Alternative 5 would result in no direct or indirect impact on public health and safety (resulting from operations and training activities).

Electromagnetic Safety

Use of the NWF to support live-fire training activities would be conducted so that new developments and training areas are consistent with established EMR hazard zones. Exposure to electromagnetic emissions would be limited by restricting access to emitters through the use of security fencing, posting warning signs, or locking out unauthorized persons in areas, where practical. Because electromagnetic emission sources would be operated in accordance with applicable safety standards and the general public would be excluded from entering areas where emission sources are located, potential long-term impacts from electromagnetic emissions on public health and safety would not result in any greater safety risk. Therefore, no direct or indirect impact on public health and safety related to electromagnetic emissions is anticipated.

Explosive Safety

Under Alternative 5, SDZs have been defined for each of the ranges in the proposed LFTRC to identify the areas requiring control of unauthorized access to live-fire training operations. The SDZs established for Alternative 5 reflect a “worst case scenario” for weapons use to ensure the safety of on- and off-range personnel and civilians. The proposed layout of the SDZs is provided in Chapter 2.

The current munitions operations and storage area have associated ESQD arcs that restrict the construction of inhabited buildings and other non-munitions related activities to minimize potential impacts on personnel and the general public from an explosive mishap. The ESQD arcs do not overlay Alternative 5 firing positions or the associated SDZs. Because the ESQD arcs do not overlay Alternative 5 firing positions or SDZs, no conflict between the current munitions storage activities and Alternative 5 activities would occur.

Ordnance used at Alternative 5 would be handled, stored, and transported in accordance with Marine Corps explosive safety directives (MCO P8020.10A, Marine Corps Ammunition Management and Explosives Safety Policy Manual), and munitions handling would be carried out by trained, qualified personnel. With implementation of appropriate range safety procedures, no direct or indirect impact on public health and safety is anticipated.

Environmental Health Effects

Noise

Potential impacts on public health and safety from Alternative 5 noise would be similar to those discussed for Alternative 1. Increases in noise emissions associated with implementation of the short-term construction phase of this alternative with identified BMPs would be less than significant. Enforcement of
OSHA guidelines for hearing protection for workers would be the responsibility of the construction contractor. Noise from Alternative 5 activities (i.e., weapons firing) would be heard at the PRTC and on adjacent lands from the range. Some adjacent lands north and west of Alternative 5 include recreational and institutional uses. However, no people would be exposed to incompatible noise levels (see Section 5.5.4.2). The noise generated from Alternative 5 activities would not result in loss of hearing to individuals in these areas, as the PRTC is located beyond Noise Zone 1 and well below the USEPA guidance of level 75 dB for long-term noise exposure (USEPA 1974). Based on the modeled noise for Alternative 5 activities (see Section 5.5.4), the overall direct or indirect impacts associated with noise on public health and safety would be less than significant.

**Water Quality**

Potential impacts on public health and safety from water quality concerns would be similar to those discussed for Alternative 1. Groundwater withdrawal would be likely to increase. However, sustainability practices would be implemented to reduce the amount of groundwater needed (see Section 5.2.2.2). The resulting total annual groundwater withdrawal would be less than the sustainable yield, and monitoring of groundwater chemistry would identify any emerging issues to ensure no harm to the water supply. Water wells on NWF have a mandated 1,000-foot (305-m) buffer identified as a wellhead protection zone. Proposed development and operational activities would be conducted in accordance with GEPA guidance and BMPs to minimize the potential for contaminants to be introduced in these areas.

Because measures would be taken to maintain a sustainable water supply and water well locations would be protected from future development and operational activities, public health and safety impacts (direct or indirect) from long-term increased demand on potable water and potential water-related illnesses would be less than significant.

**Hazardous Substances**

Potential safety impacts from use of hazardous substances would be similar to those discussed for Alternative 1. Implementation of this alternative would result in an increase in the use, handling, storage, transportation, and disposition of hazardous substances. These activities would be conducted in accordance with applicable hazardous material and waste regulations, and established BMPs and SOPs to ensure that health and safety of workers and the general public is maintained. IRP and MMRP investigations and/or remediation activities, as necessary, would continue in an effort to clean up past releases of hazardous substances that pose a risk to the general public and the environment, and receive regulator concurrence that necessary actions have been completed to ensure the safety of the general public. Because hazardous substance management and IRP and MMRP investigative/cleanup activities would be conducted in accordance with applicable regulations and established BMPs and SOPs, no direct or indirect impact on public health and safety is anticipated.

With regard to exposure to airborne toxic dust related to live-fire training activities and range maintenance, lead is the primary contaminant of concern. Very small lead particles can become airborne if wind, foot traffic, or maintenance activities disturb lead-contaminated soil. Firing ranges would be designed and constructed so that participating personnel are not exposed to airborne contaminants above permissible limits. No residential population is located near the proposed Alternative 5 and emissions migrating off range would likely be much lower than on-site. Analysis of firing range emissions presented in the 2010 Final EIS (Volume 2, Chapter 5: Air Quality, Section 5.2.7, Summary of Impacts, Table 5.2-5, page 5-36) indicated that operations emissions from firing range components would be well below significance criteria. Because range maintenance procedures ensure that participating personnel are not exposed to airborne contaminants above permissible limits and analysis of firing range emissions are...
below significance criteria, a less than significant direct or indirect impact on public health and safety from firing range activities is anticipated.

**Unexploded Ordnance**

Potential impacts from UXO would be similar to those discussed for Alternative 1. Excavation for building foundations, roads, underground utilities, and other infrastructure could encounter unexploded military munitions in the form of UXO, DMM, and/or MPPEH. Exposure to MEC could result in death or injury to workers with the exception of public access provisions outlined through the 2011 PA process (see Section 4.4.10, Cultural Resources); the general public would be excluded from entering construction zones and training areas. To reduce the potential hazards related to the exposure to MEC, ESS documentation would be prepared to outline specific measures that would be implemented to ensure the safety of workers and the general public. BMPs that would be implemented would include having qualified UXO personnel perform surveys to identify and remove potential MEC items before beginning ground-disturbing activities. Additional safety precautions would include having UXO personnel supervision during earth-moving activities and providing MEC awareness training to construction personnel involved in grading and excavations before and during ground-disturbing activities. In addition, the DON provides MEC awareness training to GovGuam and other public representatives allowing access to project sites to facilitate surveys or collection of natural resources or items of cultural significance prior to conducting vegetation clearance. Because UXO would be identified and removed before beginning construction activities and construction personnel would be trained about the hazards associated with unexploded military munitions, potential direct or indirect impacts from encounters with UXO would be minimized and would be less than significant.

**Traffic Incidents**

Potential long-term traffic incident increases would be small (5% increase [see Section 4.1.17.2]). Because no high crash frequency intersections are located near NWF and the overall potential long-term increase in the number of traffic accidents as a result of the increase in personnel would be minimal, a less than significant impact is anticipated on the health and safety of the citizens of Guam.

**5.5.18 Environmental Justice and the Protection of Children**

**5.5.18.1 Affected Environment**

The affected environment under Alternative 5 is considered to be the entire island of Guam, as discussed in Section 4.1.18.1 of this SEIS. The proposed action under Alternative 5 would be located within the northern region of Guam, as defined in Section 4.1.18.1. The villages of Dededo and Yigo are within this region.

**5.5.18.2 Environmental Consequences**

Potential impacts to environmental justice populations from Alternative 5 would be related to noise, recreation, and public health and safety. There would be no impacts from land acquisition, since Alternative 5 does not require federal land acquisition. The impact analysis discussion provided in the following sections is focused primarily on operational impacts of implementing the proposed LFTRC alternative, as LFTRC construction impacts as related to environmental justice would be minimal and short-term, with no measurable effect on Guam’s special-status populations.
Noise

Similar to Alternative 3, there would be no impact due to construction noise under this alternative because construction activities would be within the NWF away from any sensitive receptors. Construction areas along the access road to Ritidian Point would be approximately 0.25 mile (0.4 km) away from the nearest receptors.

There would be no direct impacts due to live-fire training noise under this alternative because there would be no populated residential areas affected and none of the noise significance criteria stated in the Marine Corps Guidance memo for land use and noise exposure would be exceeded, as described in Section 5.5.4, Noise. There would be no direct impacts because no population is affected and none of the significance criteria would be exceeded.

There would be environmental justice impacts from noise during the operational phase due to the HG Range at Andersen South. These impacts would be the same as described under Alternative 1.

Recreation

As described in Section 5.5.7, Recreational Resources, there are numerous public recreational resources in northern Guam. Recreational resources that would potentially be affected by implementation of Alternative 5 include beaches (e.g., Tarague Beach), picnic sites, campsites, and the Guam NWR.

Construction would be limited to DoD lands, would not impact recreational resources, and would be temporary in nature. Significant impacts to recreational resources during the construction phase are not anticipated and would mostly be limited to slow moving construction and earth-moving equipment traversing public roads and possibly slowing the public’s access to recreational resources.

The access restrictions resulting from implementation of Alternative 5 would result in significant impacts to recreational resources and the need to relocate the USFWS Nature Center. In addition to access restrictions, there are potential indirect impacts from firing range noise, which could lessen visitor enjoyment of recreational resources in the area and affect uses by private landowners at Jinapsan Beach.

Tier 1: Are there any minority, low-income, or children populations that would be impacted?

Yes, recreational resources are generally used by all people of Guam, which includes a high proportion of racial or ethnic minorities, low-income individuals, and children.

Tier 2: Are the applicable disadvantaged groups disproportionately affected by the negative environmental consequences of the proposed action(s)?

No, minority and low-income populations and children are not disproportionately affected by the increase in demand to recreation areas, because the entire region has a minority or special status population. All people of Guam would be affected by impacts to recreational resources. Therefore, Alternative 5 would not result in disproportionately high and adverse effects on minority or low-income populations nor would there be disproportionate risks to the health and safety of children.

Public Health and Safety

The potential impacts would be the same as Alternative 1.
5.6 **NO-ACTION ALTERNATIVE**

The 2010 ROD deferred selection of a specific site for an LFTRC on Guam. Consequently, under the No-Action Alternative for this SEIS, no LFTRC would be developed. The existing conditions would be unchanged and there would be no impacts to any of the resource areas under the No-Action Alternative in Chapter 5.

5.7 **SUMMARY OF IMPACTS AND POTENTIAL MITIGATION MEASURES FOR THE LIVE-FIRE TRAINING RANGE COMPLEX ALTERNATIVES**

Table 5.7-1 summarizes the impacts and potential mitigation measures for each LFTRC alternative evaluated in this chapter. Impacts include both construction and operation impacts. As discussed in Section 5.6, under the No-Action Alternative, the LFTRC would not be constructed and there would be no impacts to any of the resource areas discussed in this SEIS associated with the LFTRC. Thus, the No-Action Alternative is not presented in Table 5.7-1.
### Potential Mitigation Measures

#### Potential mitigation is not considered feasible for this impact because smaller cut/fill volumes would not provide the necessary level surfaces for the referenced ranges and roadway.

- **LSI**: Minor changes in surface elevations due to excavation and filling for the HG Range would have direct, long-term, less than significant impacts.

#### Potential Mitigation Measures Similar to Alternative 1, i.e., potential mitigation is not considered feasible and is not proposed.

- **LSI**: Minor changes in surface elevations due to excavation and filling for the HG Range would have direct, long-term, less than significant impacts.

---

**Surface Water**

**NI**
No surface waters are located within or near the construction area. There would be no significant direct or indirect short-term impacts to surface water.

**LSI**
Potential short-term increase in stormwater runoff and associated pollutants during construction could have indirect effects on surface water features. Short-term direct impacts would occur to up to 5 streams due to construction activities within and adjacent to surfaces waters. However, through compliance with the Construction General Permit and implementation of SWPPPs and associated erosion control, runoff reduction, and sediment removal BMPs, these effects would be minimized.

**Groundwater**

**LSI**
Potential for stormwater to reach NGLA. Stormwater runoff and sinkhole protection measures would serve to protect groundwater quality, resulting in less than significant direct or indirect short-term impacts.

**NI**
Similar to Alternatives 2 and 3, since the Alternative 4 project area (not including the HG Range) overlaps the Alternatives 2 and 3 project areas.

**Nearshore Waters**

**NI**
Stormwater runoff from the project area would not enter nearshore waters.

---

### Potential Mitigation Measures

**If LEDPA, a Section 404 permit would be obtained for unavoidable impacts to jurisdictional wetlands. Direct impacts would be mitigated by creating new wetlands, restoring or enhancing existing wetlands, or preserving existing wetlands areas on Guam to, at a minimum, replace the area filled.**

**LSI** Potential increase in stormwater runoff and associated pollutants could have indirect effects on wetlands. These short-term, indirect impacts would be minimized through the Construction General Permit and implementing BMPs to reduce/prevent site- and activity-specific stormwater runoff protection requirements.

**LSI** Similar to Alternative 2, resulting in short-term, indirect impacts.

**LSI** Similar to Alternative 2 resulting in short-term, indirect impacts.

Such instances are expected to be extremely rare or nonexistent during implementation of this alternative, and collectively would not represent a significant impact.</td>
<td>Traditionally use areas that would be restricted to hold social gatherings, then the access restrictions could impact those groups by deteriorating the social networks inherent in those groups. Also, as social networks may deteriorate due to the access restrictions, feelings of injustice may arise. While there is potential for social networks to deteriorate, it is not a certainty. Given the presence of other public recreation areas nearby, potential impacts are determined to be less than significant.</td>
</tr>
</tbody>
</table>

**Economic Impacts of Land Acquisition**

**LSI**

There would be a direct reduction in revenue to GovGuam of $472,000 over the 2015-2018 period resulting in lost license/lease revenue from the Guam International Raceway and the coral quarry. However, because the land acquisition process would compensate for highest and best use, there would be no impact to GovGuam associated with this loss of revenue.

**LSI**

There would be a reduction of 33 acres (13 ha) of prime farmlands, leading to a potential reduction of up to $263,500/year in property tax revenue and resulting in an adverse but less than significant impact. However, the 360 acres (146 ha) of GovGuam land subject to acquisition are not currently generating income, so a sale or lease of those lands would generate a small beneficial direct economic effect.

**LSI**

There could be a potential reduction of up to $27,436/year in property tax revenue from acquisition of privately owned parcels. However, the 360 acres (146 ha) of GovGuam land subject to acquisition are not currently generating income, so a sale or lease of those lands would generate a small beneficial direct economic effect.

**LSI**

There could be a potential reduction of up to $122,000/year in property tax revenue from acquisition of privately owned parcels. However, the 205 acres (83 ha) of GovGuam land subject to acquisition are not currently generating income, so a sale or lease of those lands would generate a small beneficial direct economic effect.

**NI**

Alternative 5 would not involve acquisition of non-federal land and would therefore have no economic impact relative to land acquisition.

Consistent with the comparable alternatives, the LSI impacts to public health and safety are anticipated from management of hazardous substances, and an additional demand to public health services (e.g., hospitals, and outpatient clinics) is not anticipated, resulting in less than significant long-term direct and indirect impacts. Less than significant impacts to public safety are anticipated from operational safety concerns (i.e., explosive safety, electromagnetic safety, and construction safety). Less than significant indirect long-term impacts to public safety from firing range air emissions are anticipated. Less than significant impacts are anticipated from noise, water quality, and UXO. Impacts would not be disproportionate because regardless of where the LFTRC is located on Guam, high (relative to the U.S.) percentages of minorities, low-income residents, and children would be affected, so impacts cannot be considered disproportionate.

**Legend:** SI = significant impact; SI-M = significant impact-mitigable; LSI = less than significant impact; NI = no impact; BI = beneficial impact.

CHAPTER 6
ADDITIVE AND COLLECTIVE IMPACTS

This chapter presents two sections that evaluate the following additive and collective impacts of the Marine Corps relocation to Guam:

- Section 6.1 addresses additive impacts of the SEIS proposed action that would result specifically from the combination of a cantonment/family housing alternative with an LFTRC alternative. For example, traffic impacts associated with project-related vehicle trips between cantonment/family housing facilities and range facilities would depend on which pair of respective site alternatives is considered. Similarly, the routing of proposed new IT/COMM infrastructure to connect the ranges and the cantonment area (as described in Section 2.6 of this SEIS) would vary depending on the specific combination of cantonment and LFTRC alternatives. These project components were not addressed in Chapter 4 (cantonment impacts) or Chapter 5 (LFTRC impacts) because they would be a function of the combination of alternatives rather than any individual site alternative. Section 6.1 focuses only on those resources for which these types of additive impacts would be applicable.

- Section 6.2 addresses the “collective” impacts attributable to the overall Marine Corps relocation to Guam, which includes not only the re-analyzed actions in the 2012 Roadmap Adjustments (assessed in Chapters 4 and 5 and 6.1 of this SEIS), but also the Marine Corps relocation projects that were fully considered and analyzed in the 2010 Final EIS and remain final from the 2010 ROD, and thus do not require further analysis in this SEIS (hereinafter “2010 ROD-Related Actions”).

Unlike the preceding Chapters 4 and 5, this chapter does not contain a section pertaining to the No-Action Alternative. The No-Action Alternative for this SEIS (see Sections 2.1 and 4.5) already corresponds to the complete set of Marine Corps relocation projects that were selected for implementation in the 2010 ROD. Therefore, the collective impacts of implementing the No-Action Alternative were already analyzed in the 2010 Final EIS and summarized in the 2010 ROD.
6.1 ADDITIVE IMPACTS FROM COMBINED ALTERNATIVES

As explained above, this section focuses on the additive impacts of the SEIS proposed action that were not previously addressed in Chapters 4 and 5 because they are a product of the combination of cantonment/family housing and LFTRC site alternatives. These additive impacts may result from construction of the connecting IT/COMM infrastructure described in Section 2.6 of this SEIS, from an increase in traffic on roads connecting a cantonment/family housing area with an LFTRC, or from other characteristics of an alternative site combination.

The following nine resource areas would not be subject to additive impacts from IT/COMM installation, an increase in traffic, or any other factors associated solely with the combination of specific cantonment/family housing and LFTRC alternatives: airspace, recreation, marine biological resources, visual resources, marine transportation, utilities, land and submerged land use, socioeconomics and general services, and environmental justice. These resources are therefore not discussed further in this section.

Section 6.1.1 addresses short-term and less than significant additive impacts that would occur during construction of the IT/COMM links but would not vary appreciably with specific site combinations. Such impacts apply to geological and soil resources, water resources, noise, ground transportation, and hazardous materials and waste. Because the additive impacts described in Section 6.1.1 would be less than significant and would not vary by site combination, they are addressed qualitatively by resource area.

Section 6.1.2 addresses additive impacts (from construction and/or operations) that would vary appreciably for different site combinations (and may include some IT/COMM construction impacts). Such impacts apply to the following resource areas: air quality, terrestrial biological resources, cultural resources, and public health and safety. In addition, ground transportation is discussed in this section because traffic impacts would vary depending on the location of the cantonment/family housing and LFTRC alternatives. Section 6.1.2 describes these impacts for the various site combinations, which are grouped in some cases based on geographic proximity, due to the large number of possible site combinations.

6.1.1 ADDITIVE IT/COMM CONSTRUCTION IMPACTS THAT DO NOT VARY BY ALTERNATIVE COMBINATION

6.1.1.1 Geological and Soil Resources

The installation of IT/COMM links between any pair of cantonment/family housing and LFTRC site alternatives would result in direct, short-term impacts to geological and soil resources along the IT/COMM routes. Earthmoving activities would occur mostly within previously-disturbed roadways (the term “roadways” includes road surface plus adjacent shoulders) that do not contain important soil resources. Standard BMPs would be implemented to avoid and minimize typical construction-related impacts (e.g., erosion) and impacts would therefore be less than significant.

6.1.1.2 Water Resources

Construction associated with the IT/COMM lines would result in the potential for short-term increases in stormwater runoff and erosion. The characteristics of the potentially disturbed area would vary somewhat depending on the IT/COMM route (see Table 2.6-1 and Figure 2.6-1 in Chapter 2 for details of the specific routes for each cantonment/LFTRC combination) and, as shown in Table 6.1.1-1, some routes are closer to surface waters and wetlands than others. However, through compliance with the Construction General Permit and Program SWPPP, and implementation of site-specific SWPPPs, and associated erosion control, runoff reduction, and sediment removal BMPs (see Table 4.1.2-2 in Chapter 4 of this SEIS), these effects would be minimized and off-site transport of stormwater runoff would be unlikely,
except during extreme weather events (i.e., typhoons). In addition, roadway-specific BMPs, as identified in the most recent CNMI and Guam Stormwater Management Manual, would be implemented, as applicable. Specifically, the site-specific SWPPPs would identify appropriate BMPs for each route that would contain runoff and sediment on-site (by reducing the flow rate of runoff), thereby minimizing the suspension of sediments and promoting infiltration of runoff. These stormwater runoff protection measures would also serve to both protect surface water, groundwater, and wetlands from indirect impacts, as well as to prevent impacts to nearshore waters.

Notes: * The number of wetlands and other waters of the U.S. were tabulated based on the occurrence of a distinct surface water feature within 100 feet (30 m) of the IT/COMM footprint. Any surface water feature occurring outside of this distance would be unlikely to be affected with implementation of construction BMPs.

Because the IT/COMM lines would primarily be located in existing roadways, no direct impacts to wetlands or other waters of the U.S. are anticipated. The potential exposure to direct or indirect impacts at any one location or resource would be short-term, given that construction would not occur simultaneously along the entire IT/COMM route at any one time, and construction at any one location would be of a relatively short duration. Based on these considerations, and given that construction would comply with Construction General Permit requirements and implementation of SWPPPs and BMPs, the proposed construction activities associated with IT/COMM lines would result in less than significant impacts to water resources on any of the routes.

6.1.1.3 Noise

Noise impacts from installation of the IT/COMM lines would only occur in close proximity to the construction activities and would primarily occur along existing roadways that have higher levels of ambient noise from road traffic and other sources. Installation of the IT/COMM lines would be very short-term, lasting only a few days near any given noise receptor before moving along the road easement. Therefore, the impacts would be less than significant.

6.1.1.4 Ground Transportation

Construction of the IT/COMM links between any given combination of cantonment/family housing and LFTRC alternatives would occur primarily along existing roadways, and would potentially include clearing and grubbing, demolition of existing road pavement, excavation, filling, paving, and landscaping. During the construction period in the immediate vicinity of any given construction area along an IT/COMM route, short-term, intermittent impacts to traffic flow would include additional traffic congestion, slower speeds in construction zones, and short detours that may be caused by truck and equipment movements, construction worker vehicles, the delivery of construction materials and equipment, and removal of construction debris. Potential direct and indirect impacts to ground...
transportation resources from IT/COMM construction would be minimized with implementation of appropriate work zone traffic management strategies and BMPs. Therefore, the installation of IT/COMM infrastructure along any route would have less than significant direct and indirect short-term impacts to roadways.

6.1.1.5 Hazardous Materials and Waste

Hazardous substances are not anticipated to be widely used or generated for the installation of IT/COMM lines at or between the cantonment, housing, or LFTRC sites. These materials would continue to be managed as described in this SEIS and the 2010 Final EIS (Volume 2, Chapter 17: Table 17.2-3: Summary of BMPs and SOPs, pages 17-42 to 17-43 and Volume 7, Chapter 2: Overview of Best Management Practices and Mitigation Measures, Table 2.1-1, Summary of Key Best Management Practices [Guam and Tinian], pages 2-4 to 2-23). With regard to previously contaminated sites, installation of IT/COMM links would avoid contaminated sites to the maximum extent practicable. If IT/COMM routes were unable to avoid areas where contamination and/or MEC has been identified, a site-specific health and safety plan would be used to ensure that the risk of human exposure to contaminated media is minimized through engineering and administrative controls and appropriate personal protective equipment. In addition, Phase I and II Environmental Site Assessments would be conducted in areas requiring new or additional IT/COMM right-of-way easements prior to construction activities to ensure that project plans consider and address contaminated sites. If installation of IT/COMM links require the demolition or renovation of structures constructed prior to 1978, these structures would be inspected for PCBs, ACM, and LBP. If these materials were identified, licensed contractors would properly remove and dispose of them in accordance with relevant local and federal regulations. Installation of IT/COMM lines would result in less than significant impacts with regard to hazardous materials and waste.

6.1.2 Additive Impacts That Vary by Site Combination

6.1.2.1 Finegayan Cantonment/Family Housing Alternative A or B with Route 15 LFTRC Alternative 1

Air Quality

Finegayan Cantonment/Family Housing Alternative A with Route 15 LFTRC Alternative 1

As discussed in Section 3.3.3.1, this SEIS updated or amended the 2010 Final EIS for the following two analysis elements:

- Hot-spot concentration impacts for mobile source CO, PM, and MSATs under both construction and operation phases.
- Construction phase, island-wide annual emissions for criteria pollutants and CO\textsubscript{2}.

As discussed in Sections 3.3.3.1, 4.1.3, and 5.1.3, the on-site and off-site hot-spot analyses were conducted based on the forecasts of location-specific traffic and construction activities under the preferred alternative and the alternative with the likely maximum potential adverse effect. The analysis results indicate that the predicted hot-spot impacts are well below the applicable standards for respective pollutants. Therefore, it can be concluded that the findings shown in Sections 4.1.3 and 5.1.3 would remain the same for each of the combined alternatives and would represent minimal localized hot-spot impacts.

Construction phase, island-wide annual emissions for criteria pollutants and CO\textsubscript{2} would have combined effects from any pair of cantonment/family housing and LFTRC alternatives. The additional combined
island-wide construction emissions are considered in this chapter by combining annual emissions forecasted in Chapters 4 and 5 (see Tables 4.1.3-1 and 5.1.3-1) to determine the potential emissions impact significance using the 250 tpy threshold. Because all of the alternative LFTRC sites are located outside the two SO\textsubscript{2} nonattainment areas, there would be no additive impacts from any of the combined alternatives with respect to the CAA general conformity rule applicability requirement. Therefore, general conformity analysis would not be needed for any of the combined alternatives. Although there would be many IT/COMM line installation options along various routes, the longest route was used to conservatively estimate the emissions associated with IT/COMM line construction activities between 2018 and 2020. These scenarios with the maximum potential adverse effect of IT/COMM construction emissions were then considered for each combined alternative discussed in this Chapter.

The combined construction emissions are summarized in Table 6.1.2-1. Air quality impacts would be less than significant because construction emissions from the combined alternative would be below the significance criterion of 250 tpy for criteria pollutants. As described in Section 3.3, in contrast to criteria pollutants, there are no NAAQS significance thresholds for greenhouse gas emissions, including CO\textsubscript{2}. Nevertheless, the predicted greenhouse gas emissions levels for this combined alternative are still presented in Table 6.1.2-1 and they are less than those analyzed in the 2010 Final EIS resulting in less GHG impacts as compared to the No-Action Alternative.

*Legend: neg = negligible; NA = not applicable.*

The combined air quality impacts for this site combination would be similar to those described above for the combination with Alternative A. Because partial construction activities under this combined alternative would occur within the Tanguisson SO\textsubscript{2} nonattainment area, the CAA general conformity rule would apply to these activities. Based on the predicted annual island-wide combined SO\textsubscript{2} emissions, as shown in Table 6.1.2-2, the annual construction SO\textsubscript{2} emissions within the Tanguisson nonattainment areas would be well below the 100 tpy de minimis threshold. Therefore, the formal CAA general conformity rule determination is not required. The combined construction island-wide emissions impacts, summarized in Table 6.1.2-2, would be below the significance criterion of 250 tpy for criteria pollutants, and would therefore be less than significant for this site combination. The CO\textsubscript{2} emissions during the construction period would be less than those analyzed in the 2010 Final EIS resulting in less GHG impacts as compared to the No-Action Alternative.

Terrestrial Biological Resources

Finegayan Cantonment/Family Housing (Alternative A) with Route 15 LFTRC (Alternative 1)

Table 6.1.2-3 combines the direct impacts from Cantonment/Family Housing Alternative A and LFTRC Alternative 1 with the additive impacts from installation of the associated IT/COMM infrastructure. Overall, approximately 1,290 acres (523 ha) of limestone forest would be disturbed, representing approximately 7% of the total limestone forest currently present on Guam. In addition, approximately 1,326 acres (537 ha) of Overlay Refuge lands, or approximately 6% of Overlay Refuge lands on Guam, would be disturbed. The majority (78%) of the impacts to limestone forest would result from implementation of Alternative A (see Section 4.1.8). Approximately 20% of the impacts would result from the implementation of Alternative 1 (see Section 5.1.8), and 2% of impacts would be due to the additive impact of the IT/COMM alignment. Because the IT/COMM route covers many areas across many miles, the area impacted by the proposed IT/COMM activities would generally be made up of smaller areas of limestone forest and would not be one contiguous area. As such, the proposed IT/COMM alignment contributes very little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Finegayan/South Finegayan Cantonment/Family Housing Alternative B with Route 15 LFTRC Alternative 1

Table 6.1.2-4 combines the direct impacts of implementing Cantonment/Housing Alternative B and LFTRC Alternative 1 with the additive impacts from installation of the corresponding IT/COMM infrastructure. Overall, approximately 1,098 acres (444 ha) of limestone forest would be disturbed, representing approximately 6% of the total limestone forest currently present on Guam. The majority (74%) of the impacts to terrestrial biological resources would result from Alternative B, with 815 acres (330 ha) of limestone forest disturbed. In addition, approximately 1,030 acres (417 ha) of Overlay Refuge lands, or less than 5% of Overlay Refuge lands currently present on Guam, would be disturbed. The proposed IT/COMM alignment contributes little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Cultural Resources

Finegayan Cantonment/Family Housing Alternative A with Route 15 LFTRC Alternative 1

Adverse effects to historic properties and impacts to other cultural resources of cultural importance resulting from the implementation of Alternatives A and 5 would be equal to the combined effects and impacts of each as discussed in Chapters 4 and 5. Additional effects and impacts could also result from the construction of the IT/COMM links for these alternatives. Construction for the IT/COMM lines linking Alternative A and Alternative 1 would occur along Routes 1, 2A, 3, 3A, 4, 4A, 5, 9, 10, 15, and 17. In general, IT/COMM lines would follow existing roads; however; additional lines would be constructed at AAFB and from AAFB to Finegayan. Approximately 43% of these areas have been previously surveyed (Davis 1983; April 1984; Haun 1988; Moore et al. 1988; Kurashina et al. 1987; Kurashina et al. 1988; Amesbury and Moore 1989; Moore and Amesbury 1989; Highness and Haun 1990; Russell and Guerrero 1991; Henry et al. 1996, 1999; Hunter-Anderson 1994; Reinman and Nees 1998; Hunter-Anderson and Moore 2002, 2003; Yee et al. 2004; DeFant and Guerrero 2006; Church et al. 2009; Athens 2009; Dixon et al. 2004, 2011a, 2011b, 2015a, 2015b; Olmo et al. 2000; Grant et al. 2007; Welch 2010; Dixon and Walker 2011; DeFant 2013). As not all of the routes have been surveyed, a literature review of previous surveys and sites located within the construction corridor was undertaken and the likelihood of finding buried cultural resources within PDIA for the IT/COMM lines corridor was assessed based on the level of disturbance, the proximity of known sites, and historic land use (Dixon et al. 2014). Within the PDIA for the IT/COMM lines, approximately 0.2% of Route 1, 57% of Route 2A, 100% of Route 3, 54% of Route 3A, 4% of Route 4, 100% of Route 4A, 16% of Route 5, 64% of Route 9, none of Route 10, 59% of Route 15, and 1% of Route 17 have been surveyed.
Table 6.1.2-5 lists 11 known archaeological sites within the IT/COMM lines PDIA. One of the sites, including portions of NWF, is eligible for listing in the NRHP. Ten archaeological sites are not eligible for listing in the NRHP. The literature review indicated that there are also areas that were not previously surveyed that have potential for buried cultural resources along Routes 1, 4, 5, 15, and 17.

### Table 6.1.2-5. Archaeological Sites within the IT/COMM Lines Potential Impacted area for Finegayan Cantonment/Family Housing (Alternative A) and Route 15 LFTRC (Alternative 1)

**Legend:** GHPI = Guam Historic Properties Inventory; NRHP = National Register of Historic Places; NA=not applicable; NRHP criterion A = eligible because they are associated with events that have made a significant contribution to the broad pattern of history; criterion D = eligible for potential to yield information important in prehistory or history.

†Not all sites recorded within the project areas have received official GHPI numbers, although they have been documented as part of previous surveys.

Notes: *Map Numbers from Welch (2009) and Welch (2010).

**Revised to match Guam GHPI forms dated May 28, 2014.

***The Guam SHPO concurs with this recommendation (Guam SHPO correspondence dated July 2 and September 17, 2014 [RC2013-0853]).

One structure eligible for listing in the NRHP, North Field, is located within the potential impacted area. No TCPs have been identified in the potential impacted areas for the IT/COMM lines.

The installation of IT/COMM links between Alternative A and the LFTRC Alternative 1 has the potential to result in adverse effects from excavation and soil removal to two historic properties, including one NRHP-eligible archaeological site (see Table 6.1.2-5) and one NRHP-eligible structure (North Field). Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the remaining areas. No TCPs would be directly affected by the construction of the IT/COMM links.
No direct or indirect adverse effects are anticipated to occur due to operation of the IT/COMM utilities as these lines would be buried and there would be no change in use and no effects to the setting.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. To the degree possible, impacts to historic properties and other resources of cultural importance would be avoided during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, potential minimization and mitigation measures may include data recovery and monitoring during construction. However, final mitigation will be determined after completion of the consultation process outlined in the PA. With the implementation of these measures and processes as outlined in the 2011 PA, additive impacts associated with IT/COMM would be reduced to a level below significance.

**Finegayan/South Finegayan Cantonment/Family Housing Alternative B with Route 15 LFTRC Alternative 1**

Adverse effects to historic properties under NHPA and impacts to other cultural resources of cultural importance resulting from the implementation of Alternatives A and 5 would be equal to the combined effects and impacts of each as discussed in Chapters 4 and 5. Additional effects and impacts could also result from the construction of the IT/COMM links for these alternatives. The PDIA for the IT/COMM lines associated with this site combination would be similar to that described above for Alternative A and Alternative 1. The installation of IT/COMM links between Alternative B and the LFTRC Alternative 1 has the potential to cause adverse effects from excavation and soil removal to two historic properties, including one NRHP-eligible archaeological site (see Table 6.1.2-5) and one NRHP-eligible structure (North Field). Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the remaining areas. No TCPs would be directly affected by the construction of the IT/COMM links.

No direct or indirect adverse effects are anticipated to occur due to operation of the IT/COMM utilities as these lines would be buried and there would be no change in use, and no effects to the setting.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. To the degree possible, impacts to historic properties and other resources of cultural importance would be avoided during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, potential minimization and mitigation measures may include data recovery and monitoring during construction. However, final mitigation will be determined after completion of the consultation process outlined in the PA. With the implementation of these measures and processes as outlined in the 2011 PA, additive impacts associated with IT/COMM would be reduced to a level below significance.

**Ground Transportation**

**Finegayan Cantonment/Family Housing Alternative A with Route 15 LFTRC Alternative 1**

The travel demand modeling methodology for the combination of alternatives was defined and directed by the DoD and the FHWA to provide detailed off-base (external) roadway and intersection analysis for one representative pairing (the modeled combination) of each cantonment/family housing alternative with one of the LFTRC site alternatives.
The modeled combination for Cantonment/Family Housing Alternative A included a pairing with LFTRC Alternative 5 (see Section 3.12). Although Alternative 5 was used for the modeled combination, the results allowed for a thorough qualitative assessment of impacts associated with the other cantonment/family housing and LFTRC alternative combinations as well. Modeling results for this scenario indicate that weekday a.m. peak hour vehicle traffic related to the proposed action is generated solely by operations at the cantonment/family housing area. LFTRC-related traffic would occur prior to the start of weekday a.m. peak hour (8:00 a.m.) and may coincide with the weekday p.m. peak hour (4:30 p.m. to 5:30 p.m.) (see Section 5.1.12). Operations of the LFTRC would increase traffic on the off-base (external) roadway segments and intersections that comprise the most direct route between the main cantonment gate and the LFTRC gates by approximately 38 vehicles (measured in passenger car equivalents) (see Table 5.1.12-2 in Chapter 5). LFTRC-related traffic represents an insubstantial amount of traffic (less than 5%) along the route. This minimal incremental increase in traffic volumes would not adversely affect LOS on roadways or at intersections along the route. The relative contribution from LFTRC traffic to the off-base (external) roadway segment and intersection impacts of each cantonment/family housing alternative would be minimal and would not vary appreciably with any LFTRC pairing (Alternative 1, 2, 3, 4, or 5). Therefore, the impacts to off-base (external) roadway segments and intersections would be essentially the same for Alternative A with Alternative 1, Alternative A with Alternative 2, 3, or 4, and Alternative A with Alternative 5. A qualitative discussion of the potential effects of LFTRC-related traffic is provided for each combination.

Pairing Alternative A with Alternative 1 may result in a slight increase in vehicles (less than 5%) on roadway segments and at intersections that comprise the most direct route between the Alternative A Main Gate and the Alternative 1 gate, and a slight decrease in vehicles compared to the modeled combination Alternative A Main Gate and the Alternative 5 gate (Figure 6.1.2-1). This minimal incremental increase or decrease in traffic volumes would not adversely affect LOS on roadways or at intersections along the route. The impacts to off-base (external) roadway segments and intersections are summarized in Table 6.1.2-6.

6-12
Roadway Segment Operations. A capacity analysis was conducted to determine potential impacts to the off-base (external) roadway network during weekday a.m. and p.m. peak hours. The volume to capacity (v/c) ratio and LOS for each study roadway segment was compared to the baseline conditions to determine if any significant impacts would occur. The detailed results of the roadway segment analysis are provided in their entirety in Appendix F.

The addition of traffic generated by the proposed action would result in a potentially significant impact on eight study roadway segments in at least one direction during the weekday a.m. and/or weekday p.m. peak hours:

- **Route 1, from Route 3 to Route 34.** This study roadway segment currently operates at acceptable LOS E with a v/c ratio of 0.99 in the northbound/eastbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.01 in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative A Conditions, this study roadway segment would continue to operate at LOS F with a v/c ratio of 1.08. The proposed action would increase traffic on this study roadway segment by approximately 180 vehicles during the weekday p.m. peak hour. This 6.9% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact in the northbound/eastbound direction on this study roadway segment during the weekday p.m. peak hour.

- **Route 1, from Route 34 to Route 16.** This study roadway segment currently operates at acceptable LOS E with a v/c ratio of 0.96 in the in the northbound/eastbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would operate at acceptable LOS E with a v/c ratio of 0.97 in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative A Conditions, this study roadway segment would degrade to unacceptable LOS F with a v/c ratio of 1.08. Therefore, the proposed action would result in a significant impact in the northbound/eastbound direction on this study roadway segment during the weekday p.m. peak hour.

- **Route 3, from Route 3A/9 to Finegayan Main Gate.** This study roadway segment currently operates at acceptable LOS B with a v/c ratio of 0.64 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would operate at acceptable LOS C with a v/c ratio of 0.75 in the southbound/westbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative A Conditions, this study roadway segment would degrade to unacceptable LOS F with a v/c ratio of 1.02. Therefore, the proposed action would result in a significant impact on this study roadway segment in the southbound/westbound during the weekday a.m. peak hour.

- **Route 3, from Finegayan Main Gate to Finegayan Residential Gate.** This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.09 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.24 in the southbound/westbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative A Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.41. The proposed action would increase traffic on this study roadway segment by approximately 128 vehicles during the weekday p.m. peak hour. This 12.3% increase in traffic exceeds the 5.0% threshold of
significance. Therefore, the proposed action would result in a significant impact on this study roadway segment in the southbound/westbound direction during the weekday a.m. peak hour.

- **Route 3, from Finegayan Residential Gate to Route 28.** This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.23 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would operate at LOS F with a v/c ratio of 1.36 in the southbound/westbound during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative A Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.61. The proposed action would increase the traffic on this study roadway segment by approximately 183 vehicles during the weekday a.m. peak hour. This 15.4% increase in traffic is greater than the 5.0% threshold of significance.

- **Route 3, from Route 28 to South Finegayan Main Gate.** This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.07 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.25 in the southbound/westbound during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative A Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.36. The proposed action would increase traffic on this study roadway segment by approximately 161 vehicles during the weekday a.m. peak hour. This 7.0% increase in traffic would exceed the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact in the southbound/westbound direction on this study roadway segment during the weekday a.m. peak hour.

- **Route 3, from South Finegayan Main Gate to Route 1.** This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 2.11 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. Construction of roadway improvements (i.e., signalization of the intersections at Guam Regional Medical City and Okkodo High School and provision of an additional southbound through lane on Route 3) would increase the capacity of this roadway segment. However, despite the fact that these improvements would be constructed prior to Year 2030, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.35 in the southbound/westbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative A Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.45. The proposed action would increase traffic on this study roadway segment by approximately 161 vehicles during the weekday a.m. peak hour. This 7.0% increase in traffic...
exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact in the southbound/westbound direction on this study roadway segment during the weekday a.m. peak hour.

- Route 28, from Chalan Balako to Route 3. This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.08 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would continue to operate at LOS F with a v/c ratio of 1.48 in the southbound/westbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative A Conditions, this study roadway segment would continue to operate at LOS F with a v/c ratio of 1.56 in the southbound/westbound direction during the weekday a.m. peak hour. The proposed action would increase the traffic on this study roadway segment by approximately 54 vehicles during the weekday a.m. peak hour. This 5.1% increase in traffic is greater than the 5.0% threshold of significance.

- During the weekday p.m. peak hour, this study roadway segment currently operates at acceptable LOS B with a v/c ratio of 0.68 in the northbound/eastbound direction under Existing Conditions. This study roadway segment would operate at acceptable LOS E in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative A Conditions, this study roadway segment would degrade to operate at unacceptable LOS F with a v/c ratio of 1.04 in the northbound/eastbound direction during the weekday p.m. peak hour. Therefore, the proposed action would result in a significant impact on this study roadway segment in the southbound/westbound direction during the weekday a.m. peak hour and in the northbound/eastbound direction during the weekday p.m. peak hour.

To reduce impacts to less than significant levels on these study roadway segments, the following potential mitigation measures may be implemented:

- Potential Mitigation Measure Fin-Roads-1: Provide additional eastbound travel lane. Widening of the segment of Route 1, from Route 3 to Route 34, a distance of approximately 0.5 mile (1.0 km) would be required to provide one additional travel lane in the eastbound direction. With implementation of Potential Mitigation Measure Fin-Roads-1, LOS on this study roadway segment would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

While the significant impact could be mitigated with the addition of an eastbound travel lane, GDPW may wish to consider adding a westbound travel lane to increase capacity and improve traffic flow in both directions along Route 1.

- Potential Mitigation Measure Fin-Roads-2: Provide additional eastbound travel lane. Widening of the segment of Route 1, from Route 34 to Route 16, a distance of approximately 0.06 mile (0.10 km), would be required to provide one additional travel lane in the eastbound direction. With implementation of Potential Mitigation Measure Fin-Roads-2, LOS on this study roadway segment would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- Potential Mitigation Measure Fin-Roads-3: Provide additional southbound travel lane. Widening of the segment of Route 3, from Route 3A/9 to Finegayan Main Gate, a distance of approximately 0.5 mile (0.8 km), would be required to provide one additional travel lane in the southbound direction. With implementation of Potential Mitigation Measure Fin-Roads-3, LOS on this study roadway segment would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)
• Potential Mitigation Measure Fin-Roads-4: Provide additional southbound travel lane. Widening of the segment of Route 3, from Finegayan Main Gate to Finegayan Residential Gate, a distance of approximately 1.75 miles (2.82 km), would be required to provide one additional travel lane in the southbound direction. With implementation of Potential Mitigation Measure Fin-Roads-4, LOS on this study roadway segment would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

• Potential Mitigation Measure Fin-Roads-5: Provide additional travel lanes in the northbound and southbound directions. Widening of the segment of Route 3, from Finegayan Residential Gate to Route 28, a distance of approximately 0.5 mile (0.8 km), would be required to provide one additional travel lane in the northbound and southbound directions. With implementation of Potential Mitigation Measure Fin-Roads-5, LOS on this study roadway segment would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

• Potential Mitigation Measure Fin-Roads-6: Provide additional southbound travel lane. Widening of the segment of Route 3, from Route 28 to South Finegayan Main Gate, a distance of approximately 0.87 mile (1.40 km), would be required to provide one additional travel lane in the southbound direction. With implementation of Potential Mitigation Measure Fin-Roads-6, LOS on this study roadway segment would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

• Potential Mitigation Measure Fin-Roads-7: Provide additional southbound travel lane. Widening of the segment of Route 3, from South Finegayan Main Gate to Route 1, a distance of approximately 1.67 miles (2.68 km), would be required to provide one additional travel lane in the southbound direction. With implementation of Potential Mitigation Measure Fin-Roads-7, LOS on this study roadway segment would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

• Potential Mitigation Measure Fin-Roads-8: Provide additional eastbound and westbound travel lanes. Widening of the segment of Route 28, from Chalan Balako to Route 3, a distance of approximately 0.97 mile (1.56 km), would be required to provide one additional travel lane in the eastbound and westbound directions. With implementation of Potential Mitigation Measure Fin-Roads-8, LOS on this study roadway segment would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

The measures needed to mitigate the impacted roadway segments would be feasible at all eight locations. The final list of implementable mitigation measures will be dependent on the selected alternative or combination of alternatives and based on project-level technical studies to be conducted after the alternative or combination of alternatives is selected. FHWA will conduct all NEPA documentation efforts and any associated resource consultations as specific mitigation measures are proposed.

Intersection Operations. Intersection analysis was conducted to determine potential impacts to the off-base (external) intersections during weekday a.m. and p.m. peak hours. The LOS for each study intersection was compared to the baseline conditions to determine if any significant impacts would occur. An impact summary is provided in Table 6.1.2-6. The detailed results of the intersection analysis are provided in their entirety in Appendix F.
The addition of traffic generated by the proposed action would potentially result in a significant impact at nine study intersections during the weekday a.m. and/or weekday p.m. peak hours.

- **Route 3 / 9 / Chalan Santa Anita.** This two-way stop-controlled study intersection currently operates at acceptable LOS C with 21.9 seconds of delay and would continue to operate at acceptable LOS E with 37.7 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative A Conditions, this study intersection would degrade to unacceptable LOS F with greater than 180.0 seconds of delay. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour.

- **Route 3 / Royal Palm Drive.** This two-way stop-controlled study intersection currently operates at acceptable LOS C with 16.3 seconds of delay and would operate at acceptable LOS E with 36.4 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative A Conditions, this study intersection would degrade to unacceptable LOS F with 54.1 seconds of delay. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour.

- **Route 1 / Route 3.** This signalized study intersection currently operates at LOS F and would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. During the weekday p.m. peak hour this study intersection currently operates at LOS E with 70.8 seconds of delay and would continue to operate at LOS E with 63.4 seconds of delay during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative A Conditions, this study intersection would continue to operate at LOS F with greater than 180.0 seconds of delay and the proposed action would add more than 50 vehicles to this poorly performing intersection during the weekday a.m. peak hour. During the weekday p.m. peak hour the intersection would degrade to operate at unacceptable LOS F with 83.0 seconds of delay. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. and p.m. peak hours.

- **Route 1 / Route 27.** This signalized study intersection currently operates at acceptable LOS E with 70.3 seconds of delay and would operate at unacceptable LOS F with 118.3 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively, Under Year 2030 Alternative A Conditions, this study intersection would continue to operate at unacceptable LOS F with 121.6 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour.

- **Route 1 / Route 26.** This signalized study intersection currently operates at acceptable LOS C with 27.9 seconds of delay and would operate at unacceptable LOS F with 87.6 seconds of delay during the weekday p.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative A Conditions, this study intersection would continue to operate at unacceptable LOS F with 91.9 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday p.m. peak hour.
- **Route 16 / Route 27.** This signalized study intersection currently operates at acceptable LOS D with 50.1 seconds of delay and acceptable LOS E with 71.2 seconds of delay during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions. This signalized study intersection would operate at unacceptable LOS F with greater than 180.0 seconds of delay and 154.7 seconds of delay during the weekday a.m. and p.m. peak hours, respectively under Year 2030 Baseline Conditions. Under Year 2030 Alternative A Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay and 160.9 seconds of delay during the weekday a.m. and p.m. peak hours, respectively. The project would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. and p.m. peak hours.

- **Route 16 / Route 10A.** This signalized study intersection currently operates at unacceptable LOS F and would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative A Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay. The project would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour.

- **Route 1 / Route 14A.** This signalized study intersection currently operates at unacceptable LOS F with 156.1 seconds of delay during the weekday p.m. peak hour under Existing Conditions. This study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday p.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative A Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday p.m. peak hour.

- **Route 1 / Route 10A.** This signalized study intersection currently operates at acceptable LOS E with 62.6 seconds of delay and would operate at unacceptable LOS F with 139.3 seconds of delay during the weekday p.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative A Conditions, this study intersection would continue to operate at unacceptable LOS F with 144.7 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday p.m. peak hour.

To reduce impacts to less than significant levels on these study intersections, the following potential mitigation measures may be implemented:

- **Potential Mitigation Measure Fin-Int-1:** Combine Route 3, 3A and 9 into one signalized intersection. Combine Route 3, 3A and 9 into one signalized intersection with the following configuration:
  - Northbound (Chalan Santa Anita): one left turn lane with 150-foot (46-m) storage pocket, one shared through/right-turn lane.
  - Southbound (Route 3A): One left turn lane with 200-foot (61-m) storage pocket and one shared through/right-turn lane.
O Eastbound (Route 3) and westbound (Route 8): one left-turn lane with 200-foot (61-m) storage pocket, one through lane, and one shared through/right-turn lane.

With implementation of Potential Mitigation Measure Fin-Int-1, LOS at this study intersection would improve and the significant impact would be mitigated to less than significant levels. The new combined intersection would operate at LOS C (21.6 seconds of delay) and LOS B (13.2 seconds of delay) during the weekday a.m. and p.m. peak hours, respectively. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-Int-2**: Add exclusive eastbound right-turn lane on Royal Palm Drive. Provide an exclusive eastbound right-turn lane on Royal Palm Drive with 100-foot (30-m) storage pocket. With implementation of Potential Mitigation Measure Fin-Int-2, LOS at this study intersection would improve and the significant impact would be mitigated to less than significant levels. The Route 3/Royal Palm Drive two-way stop-controlled intersection would operate at LOS E (45.4 seconds of delay) and LOS C (15.7 seconds of delay) during the weekday a.m. and p.m. peak hours, respectively. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-Int-3**: Add second eastbound left-turn lane and exclusive westbound right-turn lane on Route 1. Provide a second eastbound left-turn lane and an exclusive westbound right-turn lane with 200-foot (61-m) storage pocket on Route 1. Provide an acceleration lane on westbound Route 1 for southbound right-turning vehicles from Route 3. Relocate the pedestrian crossing to the east leg of the intersection. Coordinate signal with the new signal on Route 3 being constructed as part of the Guam Regional Medical City hospital. With implementation of Potential Mitigation Measure Fin-Int-3, operations at this signalized intersection would improve and the significant impact would be mitigated to less than significant levels. The Route 1/Route 3 signalized intersection would operate at LOS F (118.8 seconds of delay) and LOS B (15.5 seconds of delay) during the weekday a.m. and p.m. peak hours, respectively. Although the intersection would continue to operate at LOS F during the weekday a.m. peak hour, average intersection delay under Year 2030 Alternative A with LFTRC at NWF (Alternative 5) Conditions would be less than the average intersection delay under Year 2030 Baseline Conditions. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-Int-4**: Restripe southbound (Salisbury Street) approach and provide northbound right-turn overlap phase on Route 27. Restripe the southbound (Salisbury Street) approach to one left-turn lane with 80 feet (24 m) storage length, one through lane and one right-turn lane with 50 feet (15 m) storage length. Provide a right-turn overlap phase on the northbound (Route 27) approach. With implementation of Potential Mitigation Measure Fin-Int-4, LOS at this signalized intersection would improve and the significant impact would be mitigated to less than significant levels. The Route 1/Route 27 signalized intersection would improve to operate at LOS F (97.3 seconds of delay) and LOS D (44.1 seconds of delay) and LOS D (38.8 seconds of delay) during the weekday a.m. and p.m. peak hours, respectively. Although the intersection would continue to operate at LOS F during the weekday a.m. peak hour, average intersection delay under Year 2030 Alternative A with LFTRC Alternative 5 Conditions would be less than the average intersection delay under Year 2030 Baseline Conditions. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-Int-5**: Provide northbound right-turn overlap phase on Route 26. Provide a right-turn overlap phase on the northbound (Route 26) approach. With implementation of Potential Mitigation Measure Fin-Int-5, LOS at this signalized intersection would improve and the significant impact would be mitigated to less than significant levels. The
Route 1/Route 26 signalized intersection would operate at LOS D (35.2 seconds of delay) and LOS E (64.2 seconds of delay) during the weekday a.m. and p.m. peak hours, respectively. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-Int-6: Convert westbound right-turn lane to through lane and provide exclusive westbound and eastbound right-turn lanes on Route 27.** Widen and reconfigure the westbound (Route 27) approach. Convert the existing right-turn lane to a westbound (Route 27) through lane and add an exclusive westbound (Route 27) right-turn lane with 150 feet (46 m) storage length. Provide an exclusive eastbound (Route 27) right-turn lane with 150 feet (46 m) storage length. With implementation of Potential Mitigation Measure Fin-Int-8, LOS at this signalized intersection would improve and the significant impact would be mitigated to less than significant levels. The Route 16/Route 27 signalized intersection would operate at LOS F (117.1 seconds of delay) and LOS D (91.5 seconds of delay) during the weekday a.m. and p.m. peak hours, respectively. Although the intersection would continue to operate at LOS F during the weekday a.m. and p.m. peak hours, average intersection delay under Year 2030 Alternative A with LFTRC Alternative 5 Conditions would be less than the average intersection delay under Year 2030 Baseline Conditions. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-Int-7: Provide free southbound right-turn on Route 16.** Provide a free right-turn on the southbound (Route 16) approach. With implementation of Potential Mitigation Measure Fin-Int-7, operations at intersection would improve and the significant impact would be mitigated to less than significant levels. The Route 16/Route 10A signalized intersection would operate at acceptable LOS E (55.4 seconds of delay) and LOS D (52.2 seconds of delay) during the weekday a.m. and p.m. peak hours, respectively. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-Int-8: Provide exclusive eastbound right-turn lane on Route 1.** Widen and reconfigure the eastbound (Route 1) approach. Provide an exclusive eastbound (Route 1) right-turn lane with 150 feet (46 m) storage length. With implementation of Potential Mitigation Measure Fin-Int-8, operations at this signalized intersection would improve and the significant impact would be mitigated to less than significant levels. The Route 1/Route 14A signalized intersection would operate at acceptable LOS D (37.4 seconds of delay) and LOS F (161.9 seconds of delay) during the weekday a.m. and p.m. peak hours, respectively. Although the intersection would continue to operate at LOS F during the weekday p.m. peak hour, average intersection delay under Year 2030 Alternative A with LFTRC Alternative 5 Conditions would be less than the average intersection delay under Year 2030 Baseline Conditions. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-Int-9: Provide a free northbound right-turn lane on Route 1.** Provide a free right-turn on the northbound (Route 1) approach. With implementation of Potential Mitigation Measure Fin-Int-9, LOS at this intersection would improve and the significant impact would be mitigated to less than significant levels. The Route 1/Route 10A signalized intersection would operate at acceptable LOS D (38.4 seconds of delay) and acceptable LOS E (69.1 seconds of delay) during the weekday a.m. and p.m. peak hours, respectively. Therefore, this impact is considered to be significant but mitigable. (SI-M)
The measures needed to mitigate the impacted intersections would be feasible at all nine locations. The final list of implementable mitigation measures will be dependent on the selected alternative or combination of alternatives and based on project-level technical studies, to be conducted after the alternative or combination of alternatives is selected. FHWA will conduct all NEPA documentation efforts and any associated resource consultations as specific mitigation measures are proposed.

**Transit Conditions.** While none of the proposed cantonment/family housing or LFTRC alternatives are directly served by fixed-route transit, the proposed action may have a minor impact on the operation of Grey Line #1 by increasing travel delay at the Route 1/Route 3 intersection and the Route 1/Route 26 intersection during the weekday a.m. and p.m. peak hours. However, the increase in travel time would not be substantial and would not be expected to negatively effect on-time performance (e.g., substantially increase transit headways or reduce frequency). Additionally, implementation of Potential Mitigation Measure Fin-Int-3 and Potential Mitigation Measure Fin-Int-5 would improve operations and reduce average delay at these locations compared to Year 2030 Baseline Conditions.

**Pedestrian and Bicycle Conditions.** The proposed action would result in a significant increase in vehicular traffic on Route 3, whose northern portions near the main cantonment lack shoulders or sidewalks. This increases the potential for collisions with bicyclists and pedestrians at the locations where they are likely to be present. Specifically, Artero Drive (Finegayan Elementary School and McDonald’s) and Okkodo High School. The design requirements for the proposed action, include provision of pedestrian and bicycle facilities to be consistent with the 2030 Guam Transportation Plan. Based on recommendations and requirements included in the 2030 Guam Transportation Plan, the following pedestrian and bicycle improvements will be constructed:

- Where feasible, the outside through lanes on Route 1 should be widened to a minimum of 14.0-feet (4.2-m) to accommodate bicycle travel.
- Where feasible, 4.0-foot (1.2-m) wide shoulders should be provided on Route 3 to accommodate pedestrians and bicyclists.

Implementation of these improvements would reduce potential impacts to less than significant levels.

**Finegayan/South Finegayan Cantonment/Family Housing Alternative B with Route 15 LFTRC Alternative 1**

The travel demand modeling methodology for the combination of alternatives was defined and directed by the DoD and the FHWA to provide detailed off-base (external) roadway and intersection analysis for one representative pairing (the modeled combination) of each cantonment/family housing alternative with one of the LFTRC site alternatives. The modeled combination for Alternative B involved a pairing with LFTRC Alternative 2 or 4 (see Section 3.12 in Chapter 3). Modeling results for this scenario indicate that weekday a.m. peak hour vehicle traffic related to the proposed action is generated solely by operations at the cantonment/family housing area. LFTRC-related traffic would occur prior to the start of weekday a.m. peak hour (8:00 a.m.) and may coincide with the weekday p.m. peak hour (4:30 p.m. to 5:30 p.m.) (see Section 5.1.12 in Chapter 5). Operations of the LFTRC would increase traffic on the off-base (external) roadway segments and intersections that comprise the most direct route between the main cantonment gate and the LFTRC gates, by approximately 38 vehicles (measured in passenger car equivalents) (see Table 5.1.12-2). LFTRC-related traffic represents an insubstantial amount of traffic (less than 5%) along the route. This minimal incremental increase in traffic volumes would not adversely affect LOS on roadways or at intersections along the route. The relative contribution from LFTRC traffic to the off-base (external) roadway segments and intersections of each cantonment/family housing alternative would be minimal and would not vary appreciably with any LFTRC pairing (Alternative 1, 2, 3, 4, or 5). Therefore,
the impacts to off-base (external) roadway segments and intersections would be essentially the same for Alternative B with Alternative 1, Alternative B with Alternative 2, 3, or 4, and Alternative B with Alternative 5. A qualitative discussion of the potential effects of LFTRC-related traffic is provided for each combination.

Pairing Alternative B with Alternative 1 may result in a slight increase (less than 5%) in vehicles on roadway segments and at intersections along the most direct route between the Alternative B Main Gate and the Alternative 1 gate, and a slight decrease in vehicles compared to the modeled combination of Alternative B Main Gate and the Alternative 2 or 4 gate (Figure 6.1.2-2). This minimal incremental increase or decrease in traffic volumes would not adversely affect LOS on roadways or at intersections along the route.

The impacts to off-base (external) roadway segments and intersections are summarized in Table 6.1.2-7.

**Table 6.1.2-7. Summary of Additive Impacts to Ground Transportation Resources with the Finegayan/South Finegayan Cantonment/Family Housing (Alternative B) with any LFTRC**

Roadway Segment Operations. A capacity analysis was conducted to determine potential impacts to the off-base (external) roadway network during weekday a.m. and p.m. peak hours. The LOS for each study roadway segment was compared to the baseline conditions to determine if any significant impacts would occur. The detailed results of the roadway segment analysis are provided in their entirety in Appendix F.

The addition of traffic generated by the proposed action would potentially result in a significant impact on ten study roadway segments in at least one direction during the weekday a.m. and/or weekday p.m. peak hours.

- **Route 1, from Route 3 to Route 34.** This study roadway segment currently operates at LOS E with a v/c ratio of 0.99 in the northbound/eastbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would operate at LOS F with a v/c ratio of 1.01 in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative B Conditions, this study roadway segment would continue to operate at LOS F with a v/c ratio of 1.11. The proposed action would increase traffic on this study roadway segment by approximately 250 vehicles during the weekday p.m. peak hour. This 9.3% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact in the northbound/eastbound direction on this study roadway segment during the weekday p.m. peak hour. A similar impact was identified on this study roadway segment under Year 2030 Alternative A Conditions.

- **Route 1, from Route 34 to Route 16.** This study roadway segment currently operates at acceptable LOS E with a v/c ratio of 0.96 in the northbound/eastbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would continue to operate at acceptable LOS E with a v/c ratio of 0.97 in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative B Conditions, this study roadway segment would degrade to unacceptable LOS F with a v/c ratio of 1.07. Therefore, the proposed action would result in a significant impact in the northbound/eastbound direction on this study roadway segment during the weekday p.m. peak hour. A similar impact was identified on this study roadway segment under Year 2030 Alternative A Conditions.

- **Route 3, from Route 3A/9 to Finegayan Main Gate.** This study roadway segment currently operates at acceptable LOS B with a v/c ratio of 0.64 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would continue to operate at acceptable LOS B with a v/c ratio of 0.68 during the weekday a.m. and p.m. peak hours, respectively, under Year 2030 Baseline Conditions. Under Year 2030 Alternative B Conditions, this study roadway segment would degrade to unacceptable LOS F with a v/c ratio of 1.07 during the weekday a.m. peak hour. Therefore, the proposed action would result in a significant impact on this study roadway segment in the southbound/westbound direction during the weekday a.m. peak hour. A similar impact was identified on this study roadway segment during the weekday a.m. peak hour under Year 2030 Alternative A Conditions. An impact was not identified during the weekday p.m. peak hour Year 2030 Alternative A Conditions.

- **Route 3, from Finegayan Main Gate to Finegayan Residential Gate.** This study roadway segment currently operates at acceptable LOS A with a v/c ratio of 0.45 and 0.60 in the northbound/eastbound direction during the weekday a.m. and p.m. peak hours, respectively under Existing Conditions. This study roadway segment would continue to operate at acceptable LOS A with a v/c ratio of 0.49 during the weekday a.m. peak hour and would operate at acceptable LOS B with a v/c ratio of 0.68 during the weekday a.m. and p.m. peak hours, respectively, in the
northbound/eastbound direction under Year 2030 Baseline Conditions. Under Year 2030 Alternative B Conditions, this roadway segment would degrade to operate at unacceptable LOS F with a v/c ratio of 1.17 and 1.10 during the weekday a.m. and p.m. peak hours, respectively.

This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.09 and acceptable LOS A with a v/c ratio of 0.51 in the southbound/westbound direction during the weekday a.m. and p.m. peak hours, respectively under Existing Conditions. This study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.24 in the during the weekday a.m. peak hour, and at acceptable LOS A with a v/c ratio of 0.56 in the southbound/westbound direction during the weekday a.m. and p.m. peak hours, respectively, under Year 2030 Baseline Conditions. Under Year 2030 Alternative B Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.44 and would degrade to operate at LOS F with a v/c ratio of 1.14 in the southbound/westbound direction during the weekday a.m. and p.m. peak hours, respectively. The proposed action would increase traffic on this study roadway segment by approximately 151 vehicles during the weekday a.m. peak hour. This 14.1% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact on this study roadway segment in the northbound/eastbound and southbound/westbound directions during the weekday a.m. and p.m. peak hours.

A similar impact was identified in the southbound/westbound direction on this study roadway segment during the weekday a.m. peak hour under Year 2030 Alternative A Conditions. An impact was not identified in the northbound/eastbound direction during either the weekday a.m. or p.m. peak hours, nor in the southbound/westbound direction during the weekday p.m. peak hour under Year 2030 Alternative A Conditions.

- Route 3, from Finegayan Residential Gate to Route 28. This study roadway segment currently operates at acceptable LOS B with a v/c ratio of 0.67 and LOS D with a v/c ratio of 0.81 in the northbound/eastbound direction during the weekday a.m. and p.m. peak hours, respectively under Existing Conditions. This study roadway segment would operate at acceptable LOS B with a v/c ratio of 0.70 and LOS E with a v/c ratio of 0.90 in the northbound/eastbound direction during the weekday a.m. and p.m. peak hours, respectively, in the northbound/eastbound direction under Year 2030 Baseline Conditions. Under Year 2030 Alternative B Conditions, this roadway segment would degrade to operate at unacceptable LOS F with a v/c ratio of 1.41 and 1.29 during the weekday a.m. and p.m. peak hours, respectively.

This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.23 and acceptable LOS B with a v/c ratio of 0.67 in the southbound/westbound direction during the weekday a.m. and p.m. peak hours, respectively under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.36 during the weekday a.m. peak hour, and at acceptable LOS C with a v/c ratio of 0.74 during the weekday p.m. peak hour in the southbound/westbound direction under Year 2030 Baseline Conditions. Under Year 2030 Alternative B Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.55 and would degrade to operate at LOS F with a v/c ratio of 1.44 in the southbound/westbound direction during the weekday a.m. and p.m. peak hours, respectively. The proposed action would increase traffic on this study roadway segment by approximately 143 vehicles during the weekday p.m. peak hour. This 12.5% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact on
this study roadway segment in the northbound/eastbound and southbound/westbound directions during the weekday a.m. and p.m. peak hours.

A similar impact was identified in the southbound/westbound direction on this study roadway segment during the weekday a.m. peak hour under Year 2030 Alternative A Conditions. An impact was not identified in the northbound/eastbound direction during either the weekday a.m. or p.m. peak hours, nor in the southbound/westbound direction during the weekday p.m. peak hour under Year 2030 Alternative A Conditions.

- **Route 3, from Route 28 to South Finegayan Main Gate.** This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.07 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.25 in the southbound/westbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative B Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.36 in the southbound/westbound direction. The proposed action would increase traffic on this study roadway segment by approximately 166 vehicles during the weekday p.m. peak hour. This 7.7% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact in the southbound/westbound direction on this study roadway segment during the weekday a.m. peak hour. A similar impact was identified on this study roadway segment under Year 2030 Alternative A Conditions.

- **Route 3, from South Finegayan Main Gate to Route 1.** This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 2.11 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. Construction of roadway improvements (i.e., signalization of the intersections at Guam Regional Medical City and Okkodo High School and provision of an additional southbound through lane on Route 3) would increase the capacity of this roadway segment. However, despite the fact that these improvements would be constructed prior to Year 2030, this study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.35 in the southbound/westbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative B Conditions, this study roadway segment would degrade to LOS F with a v/c ratio of 1.46. The proposed action would increase traffic on this study roadway segment by approximately 168 vehicles during the weekday a.m. peak hour. This 7.3% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact in the southbound/westbound direction on this study roadway segment during the weekday a.m. peak hour. A similar impact was identified on this study roadway segment under Year 2030 Alternative A Conditions.

- **Route 16, from Route 27 to Route 10A.** This study roadway segment currently operates at acceptable LOS D with a v/c ratio of 0.84 in the northbound/eastbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would operate at acceptable LOS E with a v/c ratio of 0.98 in the northbound/eastbound during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative B Conditions, this study roadway segment would degrade to LOS F with a v/c ratio of 1.01. Therefore, the proposed action would result in a significant impact on this study roadway segment in the northbound/eastbound direction during the weekday p.m. peak hour. No impacts were identified on this study roadway segment under Year 2030 Alternative A Conditions.
- **Route 28**, from Chalan Balako to Route 3. This study roadway segment currently operates at acceptable LOS D with a v/c ratio of 0.87 in the northbound/eastbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would operate at acceptable LOS E with a v/c ratio of 0.98 in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative B Conditions, this study roadway segment would degrade to LOS F with a v/c ratio of 1.01. Therefore, the proposed action would result in a significant impact on this study roadway segment in the northbound/eastbound direction during the weekday p.m. peak hour. A similar impact was identified on this study roadway segment under Year 2030 Alternative A Conditions. An additional impact in the southbound/westbound direction was identified during the weekday a.m. peak hour under Year 2030 Alternative A Conditions.

- **Route 16**, from Route 10A to Barrigada Main Gate. This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.09 in the northbound/eastbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.05 in the northbound/eastbound during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative B Conditions, this study roadway segment would continue to operate at LOS F with a v/c ratio of 1.11. The proposed action would increase traffic on this study roadway segment by approximately 94 vehicles during the weekday a.m. peak hour. This 5.3% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact in the northbound/eastbound direction on this study roadway segment during the weekday p.m. peak hour. No impacts were identified on this study roadway segment under Year 2030 Alternative A Conditions.

To reduce impacts to less than significant levels on these study roadway segments, the following potential mitigation measures may be implemented:

- **Potential Mitigation Measure Fin-S. Fin-Roads-1**: Implement Potential Mitigation Measure Fin-Roads-1. With implementation of Potential Mitigation Measure Fin-Roads-1, traffic operations on Route 1, from Route 3 to Route 34 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-S. Fin-Roads-2**: Implement Potential Mitigation Measure Fin-Roads-2. With implementation of Potential Mitigation Measure Fin-Roads-2, traffic operations on Route 1, from Route 34 to Route 16 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-S. Fin-Roads-3**: Implement Potential Mitigation Measure Fin-Roads-3. With implementation of Potential Mitigation Measure Fin-Roads-3, traffic operations on Route 3, from Route 3A/9 to Finegayan Main Gate would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-S. Fin-Roads-4**: Implement Potential Mitigation Measure Fin-Roads-4. With implementation of Potential Mitigation Measure Fin-Roads-4, traffic operations on Route 3, from Finegayan Main Gate to Finegayan Residential Gate would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)
• **Potential Mitigation Measure Fin-S. Fin-Roads-5**: Implement Potential Mitigation Measure Fin-Roads-5. With implementation of Potential Mitigation Measure Fin-Roads-5, traffic operations on Route 3, from Finegayan Residential Gate to Route 28 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

• **Potential Mitigation Measure Fin-S. Fin-Roads-6**: Implement Potential Mitigation Measure Fin-Roads-6. With implementation of Potential Mitigation Measure Fin-Roads-6, traffic operations on Route 3, from Route 28 to South Finegayan Main Gate would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

• **Potential Mitigation Measure Fin-S. Fin-Roads-7**: Implement Potential Mitigation Measure Fin-Roads-7. With implementation of Potential Mitigation Measure Fin-Roads-7, traffic operations on Route 3, from South Finegayan Main Gate to Route 1 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

• **Potential Mitigation Measure Fin-S. Fin-Roads-8**: Implement Potential Mitigation Measure Fin-Roads-8. With implementation of Potential Mitigation Measure Fin-Roads-8, traffic operations on Route 28, from Chalan Balako to Route 3 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

Significant impacts would also occur at two locations and potential mitigation measures have not been identified:

- Route 16, from Route 27 to Route 10A (SI)
- Route 16, from Route 10A to Barrigada Main Gate (SI)

The final list of implementable mitigation measures will be dependent on the selected alternative or combination of alternatives and based on project-level technical studies, to be conducted after the alternative or combination of alternatives is selected. FHWA will conduct all NEPA documentation efforts and any associated resource consultations as specific mitigation measures are proposed.

**Intersection Operations.** Intersection analysis was conducted to determine potential impacts to the off-base (external) intersections during weekday a.m. and p.m. peak hours. The LOS for each study intersection is compared to the baseline conditions to determine if any significant impacts would occur. An impact summary is provided in Table 6.1.2-7. The detailed results of the intersection analysis are provided in their entirety in Appendix F.

The addition of traffic generated by the proposed action would potentially result in a significant impact at 11 study intersections during the weekday a.m. and/or weekday p.m. peak hours.

- **Route 3 / 9 / Chalan Santa Anita.** This two-way stop-controlled study intersection currently operates at acceptable LOS C with 21.9 seconds of delay and would operate at acceptable LOS E with 37.7 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative B Conditions, this study intersection would degrade to unacceptable LOS F with greater than 180.0 seconds of delay. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour. A similar impact was identified under Year 2030 Alternative A Conditions.
• **Route 3 / Royal Palm Drive.** This two-way stop-controlled study intersection currently operates at acceptable LOS C with 16.3 seconds of delay and would operate at acceptable LOS E with 36.4 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative B Conditions, this study intersection would degrade to unacceptable LOS F with greater than 180.0 seconds of delay. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour. A similar impact was identified under Year 2030 Alternative A Conditions.

• **Route 15 / Chalan Lajuna.** This two-way stop-controlled study intersection currently operates at LOS D with 30.7 seconds of delay and LOS C with 23.9 seconds of delay during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions. This study intersection would operate at unacceptable LOS F with 75.8 seconds of delay and 82.6 seconds of delay during the weekday a.m. and p.m. peak hours under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative B Conditions, this study intersection would continue to operate at LOS F with 98.0 seconds of delay and 96.1 seconds of delay during the weekday a.m. and p.m. peak hours, respectively. The proposed action would not add more than 50 vehicles to this poorly performing intersection during the weekday a.m. peak hour. However, the proposed action would add more than 50 vehicles to this poorly performing intersection during the weekday p.m. peak hour. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday p.m. peak hour. No impacts were identified at this study intersection under Year 2030 Alternative A Conditions.

• **Route 1 / Route 3.** This signalized study intersection currently operates at LOS F and would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. During the weekday p.m. peak hour this study intersection currently operates at LOS E with 70.8 seconds of delay and would continue to operate at acceptable LOS E with 63.4 seconds of delay under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative B Conditions, this study intersection would continue to operate at LOS F with greater than 180.0 seconds of delay and the proposed action would add more than 50 vehicles to this poorly performing intersection during the weekday a.m. peak hour. During the weekday p.m. peak hour the intersection would degrade to operate at unacceptable LOS F with 99.8 seconds of delay. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. and p.m. peak hours. A similar impact was identified under Year 2030 Alternative A Conditions.

• **Route 1 / Route 27.** This signalized study intersection currently operates at acceptable LOS E with 70.3 seconds of delay and would operate at unacceptable LOS F with 118.3 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative A Conditions, this study intersection would continue to operate at unacceptable LOS F with 122.9 seconds of delay during the weekday p.m. peak hour. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour. A similar impact was identified under Year 2030 Alternative A Conditions.

• **Route 1 / Route 26.** This signalized study intersection currently operates at acceptable LOS C with 27.9 seconds of delay and would operate at unacceptable LOS F with 87.6 seconds of delay during the weekday p.m. peak hour under Existing Conditions and Year 2030 Baseline
Conditions, respectively. Under Year 2030 Alternative B Conditions, this study intersection would continue to operate at unacceptable LOS F with 88.1 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection during the weekday p.m. peak hour. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday p.m. peak hour. A similar impact was identified under Year 2030 Alternative A Conditions.

- **Route 16 / Route 27.** This signalized study intersection currently operates at acceptable LOS D with 50.1 seconds of delay and LOS E with 71.2 seconds of delay during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions. This study intersection would operate at unacceptable LOS F with greater than 180.0 seconds of delay and 154.7 seconds of delay during the weekday a.m. and p.m. peak hours, respectively under Year 2030 Baseline Conditions. Under Year 2030 Alternative B Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay and 166.2 seconds of delay during the weekday a.m. and p.m. peak hours, respectively. The proposed action would add more than 50 vehicles to this poorly performing intersection during the weekday a.m. and p.m. peak hours. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. and p.m. peak hours. A similar impact was identified under Year 2030 Alternative A Conditions.

- **Route 16 / Route 10A.** This signalized study intersection currently operates at unacceptable LOS F with 143.3 seconds of delay and would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative B Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection during the weekday a.m. peak hour. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour. A similar impact was identified under Year 2030 Alternative A Conditions.

- **Route 15 / Route 26.** This two-way stop-controlled intersection currently operates at unacceptable LOS F with 62.1 seconds of delay and 147.3 seconds of delay during the weekday a.m. and p.m. peak hours, respectively under Existing Conditions. This study intersection would continue to operate at unacceptable LOS F with 145.2 seconds of delay and greater than 180.0 seconds of delay during the weekday a.m. and p.m. peak hours, respectively, under Year 2030 Baseline Conditions. Under Year 2030 Alternative B Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday a.m. and p.m. peak hours. The proposed action would add more than 50 vehicles to this poorly performing intersection during the weekday a.m. and p.m. peak hours. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. and p.m. peak hours. No impacts were identified at this study intersection under Year 2030 Alternative A Conditions.

- **Route 1 / Route 14A.** This signalized study intersection currently operates at unacceptable LOS F with 156.1 seconds of delay during the weekday p.m. peak hour under Existing Conditions. This study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative B Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection during the weekday p.m. peak hour.
Therefore, the proposed action would result in a significant impact on this study intersection during the weekday p.m. peak hour. A similar impact was identified under Year 2030 Alternative A Conditions.

- **Route 1 / Route 10A.** This signalized study intersection currently operates at acceptable LOS E with 62.6 seconds of delay and would operate at unacceptable LOS F with 139.3 seconds of delay during the weekday p.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative B Conditions, this study intersection would continue to operate at unacceptable LOS F with 146.1 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday p.m. peak hour. A similar impact was identified under Year 2030 Alternative A Conditions.

To reduce impacts to less than significant levels on these study intersections, the following potential mitigation measures may be implemented:

- **Potential Mitigation Measure Fin-S, Fin-Int-1: Implement Potential Mitigation Measure Fin-Int-1.** With implementation of Potential Mitigation Measure Fin-Int-1, traffic operations at Route 3 / 9 / Chalan Santa Anita would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)
- **Potential Mitigation Measure Fin-S, Fin-Int-2: Implement Potential Mitigation Measure Fin-Int-2.** With implementation of Potential Mitigation Measure Fin-Int-2, traffic operations at Route 3 / Royal Palm Drive would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)
- **Potential Mitigation Measure Fin-S, Fin-Int-3: Implement Potential Mitigation Measure Fin-Int-3.** With implementation of Potential Mitigation Measure Fin-Int-3, traffic operations at Route 1 / Route 3 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)
- **Potential Mitigation Measure Fin-S, Fin-Int-4: Implement Potential Mitigation Measure Fin-Int-4.** With implementation of Potential Mitigation Measure Fin-Int-4, traffic operations at Route 1 / Route 27 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)
- **Potential Mitigation Measure Fin-S, Fin-Int-5: Implement Potential Mitigation Measure Fin-Int-5.** With implementation of Potential Mitigation Measure Fin-Int-5, traffic operations at Route 1 / Route 26 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)
- **Potential Mitigation Measure Fin-S, Fin-Int-6: Implement Potential Mitigation Measure Fin-Int-6.** With implementation of Potential Mitigation Measure Fin-Int-6, traffic operations at Route 16 / Route 27 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)
- **Potential Mitigation Measure Fin-S, Fin-Int-7: Implement Potential Mitigation Measure Fin-Int-7.** With implementation of Potential Mitigation Measure Fin-Int-7, traffic operations at Route 16 / Route 10A would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)
- **Potential Mitigation Measure Fin-S, Fin-Int-8: Implement Potential Mitigation Measure Fin-Int-8.** With implementation of Potential Mitigation Measure Fin-Int-8, traffic operations at Route 1 / Route 14A would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)
• Potential Mitigation Measure Fin-S. Fin-Int-9: Implement Potential Mitigation Measure Fin-Int-9.
  With implementation of Potential Mitigation Measure Fin-Int-9, traffic operations at Route 1 / Route 10A would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

Significant impacts would also occur at two locations and potential mitigation measures have not been identified:

• Route 15 / Chalan Lajuna (SI)
• Route 15 / Route 26 (SI)

The final list of implementable mitigation measures will be dependent on the selected alternative or combination of alternatives and based on project-level technical studies, to be conducted after the alternative or combination of alternatives is selected. FHWA will conduct all NEPA documentation efforts and any associated resource consultations as specific mitigation measures are proposed.

Transit Conditions. Transit conditions under Alternative B with Alternative 1 would be the same as those described above for Alternative A with Alternative 1.

Pedestrian and Bicycle Conditions. Pedestrian and bicycle conditions under Alternative B with Alternative 1 would be the same as those described above for Alternative A with Alternative 1.

Public Health and Safety

The primary health and safety issue associated with the Alternative A and Alternative 1 combination is the potential for traffic incidents. The driving distance between the proposed Finegayan alternatives (Alternatives A or B) and the proposed Route 15 LFTRC alternative (Alternative 1) is approximately 7.8 miles (12.5 km). Vehicles would use Routes 3, 9, and 1 to commute between the Alternative A or Alternative B area and Alternative 1. No high-crash frequency intersections are situated along this travel route. Because the travel distance between Alternative A or Alternative B and Alternative 1 is relatively short and there are no high-frequency crash intersections situated along the travel route, no significant additive traffic impacts are expected to occur.

The proposed action would result in a substantial increase in vehicular traffic on Route 3, whose northern portions near the main cantonment lack shoulders or sidewalks. This would increase the potential for collisions with bicyclists and pedestrians at the locations where they are likely to be present, specifically, Artero Drive (Finegayan Elementary School and McDonald’s) and Okkodo High School. Based on the hours of operation of Okkodo High School (6:45 a.m. to 3:00 p.m.) and the Guam Department of Public Works 2012-2013 bus schedule, the peak hour of school traffic would occur between 6 a.m. and 7 a.m. and 2:30 p.m. and 3:30 p.m. The peak hour of school traffic would not coincide or overlap with overall weekday peak traffic hours, which occur between 8:00 a.m. and 9:00 a.m. and between 4:30 p.m. and 5:30 p.m. Because peak school traffic would not coincide with overall weekday peak traffic hours, the increase in potential for collisions with children that would be commuting to school via walking or bicycle would be less than significant.
6.1.2.2 Finegayan Cantonment/Family Housing Alternative A or B with any NAVMAG LFTRC Alternative (Alternatives 2, 3, or 4)

Air Quality

The combined air quality impacts would be similar to those described Section 6.1.2.1. The combined construction island-wide impacts, similar to the emissions summarized in Table 6.1.2-1, would be less than significant as a result of these combined alternatives.

Terrestrial Biological Resources

Finegayan Cantonment/Family Housing Alternative A with NAVMAG (East/West) LFTRC Alternative 2

The additive impacts of implementing Cantonment Housing Alternative A, LFTRC Alternative 2, and the IT/COMM infrastructure are provided in Table 6.1.2-8. Overall, approximately 1,054 acres (428 ha) of limestone forest, or 5.6% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 1,326 acres (537 ha) of Overlay Refuge lands, or 6% of the total Overlay Refuge currently present on Guam, would be disturbed. The majority (95%) of the impacts to terrestrial biological resources would occur under Alternative A, with over 1,007 acres (408 ha) of limestone forest disturbed. The proposed IT/COMM alignment contributes very little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Table 6.1.2-8. Summary of Impacts to Terrestrial Biological Resources with Implementation of Finegayan Cantonment/Family Housing (Alternative A), NAVMAG (East/West) LFTRC (Alternative 2), and IT/COMM Infrastructure

Finegayan Cantonment/Family Housing Alternative A with NAVMAG (North/South) LFTRC Alternative 3

The additive impacts of implementing Cantonment/Family Housing Alternative A, LFTRC Alternative 3, and the IT/COMM infrastructure are provided in Table 6.1.2-9. Overall, approximately 1,203 acres (487 ha) of limestone forest, or 6% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 1,601 acres (648 ha) of Overlay Refuge lands, or 7% of the total Overlay Refuge currently present on Guam, would be disturbed. The majority (83%) of the impacts to terrestrial biological resources would occur under Alternative A, with 1,007 acres (408 ha) of limestone forest disturbed. The proposed IT/COMM alignment contributes very little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Finegayan Cantonment/Family Housing Alternative A with NAVMAG (L-Shaped) LFTRC Alternative 4

The additive impacts of implementing Cantonment/Family Housing Alternative A, LFTRC Alternative 4, and the IT/COMM infrastructure are provided in Table 6.1.2-10. Overall, approximately 1,165 acres (472 ha) of limestone forest, or 6% of the total limestone forest currently present on Guam, would be disturbed. Approximately 1,545 acres (625 ha) of Overlay Refuge lands, or 7% of the total Overlay Refuge currently present on Guam, would be disturbed. The proposed IT/COMM alignment contributes very little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Finegayan/South Finegayan Cantonment/Family Housing Alternative B with NAVMAG (East/West) LFTRC Alternative 2

The additive impacts of implementing Cantonment/Family Housing Alternative B, LFTRC Alternative 2, and the IT/COMM infrastructure are provided in Table 6.1.2-11. Overall, approximately 862 acres (350 ha) of limestone forest, or 5% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 1,060 acres (429 ha) of Overlay Refuge lands, or 5% of the total Overlay Refuge currently present on Guam, would be disturbed. The vast majority (95%) of the impacts to terrestrial biological resources would occur under Alternative B, with 815 acres (330 ha) of limestone forest disturbed. The proposed IT/COMM alignment contributes very little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Finegayan/South Finegayan Cantonment/Family Housing Alternative B with NAVMAG (North/South) LFTRC Alternative 3

The additive impacts of implementing Cantonment/Family Housing Alternative B, LFTRC Alternative 3, and the IT/COMM infrastructure are provided in Table 6.1.2-12. Overall, approximately 1,012 acres (410 ha) of limestone forest, or 5% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 1,305 acres (5284 ha) of Overlay Refuge lands, or 6% of the total Overlay Refuge currently present on Guam, would be disturbed. The majority (80%) of the impacts to vegetation communities would occur under Alternative B, with 815 acres (330 ha) of limestone forest disturbed. The proposed IT/COMM alignment contributes little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Cultural Resources

Finegayan Cantonment/Family Housing Alternative A with any NAVMAG LFTRC Alternative (Alternatives 2, 3, or 4)

Adverse effects to historic properties under NHPA and impacts to other cultural resources of cultural importance resulting from the implementation of Alternative A and Alternatives 2, 3, or 4 would be equal to the combined effects and impacts of each as discussed in Chapters 4 and 5. Additional effects and impacts could also result from the construction of the IT/COMM links for these alternatives. Construction for the IT/COMM lines for Alternative A and Alternatives 2, 3, or 4 would occur along Routes 1, 2A, 3, 3A, 4, 4A, 5, 8, 9, 10, 15, 16, and 17. In general, IT/COMM lines would follow existing roads; however, additional lines would be constructed at AAFB and from AAFB to Finegayan. Approximately 48% of these areas have been previously surveyed (Thomas and Price 1979; Davis 1983; April 1984; Haun 1988; Kurashina et al. 1988; Amesbury and Moore 1989; Moore et al. 1988; Moore and Amesbury 1989; Highness and Haun 1990; Amesbury et al. 1991; Carrell 1991; Russell and Guerrero 1991; Prasad and Moore 1992; Russell et al. 1993; Henry et al. 1994, 1999; Hunter-Anderson 1994; Reinman 1995; Wells et al. 1995; Workman and Haun 1995; Hunter-Anderson et al. 1997; Reinman and Nees 1998; Olmo et al. 2000; Hunter-Anderson et al. 1995, 2001; Kurashina et al. 1987; Liston 1996; Hunter-Anderson and Moore 2002, 2003; Dixon et al. 1999, 2004, 2011a, 2011b, 2015a, 2015b; Yee et al. 2004; DeFant and Guerrero 2006; Hunter-Anderson 2002, 2004; Grant et al. 2007; Church et al. 2009; Athens 2009; Welch 2010; Dixon and Walker 2011; DeFant 2013). As not all of the routes have been surveyed, a literature review of previous surveys and sites located within the construction corridor was undertaken and the
likelihood of finding buried cultural resources within PDIA for the IT/COMM lines corridor was assessed based on the level of disturbance, the proximity of known sites, and historic land use (Dixon et al. 2014). Within the PDIA for the IT/COMM lines, 39% of Route 1, 61% of Route 2A, 100% of Route 3, 54% of Route 3A, 11% of Route 4, 100% of Route 4A, 16% of Route 5, 90% of Route 8, 64% of Route 9, none of Route 10, 59% of Route 15, 55% of Route 16, and 2% of Route 17 have been surveyed.

Table 6.1.2-14 lists 12 known archaeological sites within the IT/COMM lines PDIA for Alternatives 2, 3, and 4. One site, a portion of NWF, is eligible for inclusion in the NRHP. Eleven archaeological sites are not eligible for listing in the NRHP. The literature review indicated that there are also areas that were not previously surveyed that have potential for buried cultural resources along Routes 1, 5, 15 and 17.

**Legend:** GHPI = Guam Historic Properties Inventory; NRHP = National Register of Historic Places; NA = not applicable; NRHP criterion A = eligible because they are associated with events that have made a significant contribution to the broad pattern of history, criterion D = eligible for potential to yield information important in prehistory or history.

**Notes:**
†Not all sites recorded within the project areas have received official GHPI numbers, although they have been documented as part of previous surveys.
**Revised to match Guam GHPI forms dated May 28, 2014.
***The Guam SHPO concurs with this recommendation (Guam SHPO correspondence dated July 2 and September 17, 2014 [RC2013-0853]).

One structure eligible for listing in the NRHP, North Field, is also located within the potential impacted area for Alternatives 2, 3, and 4. No TCPs have been identified in the potential impacted areas for the IT/COMM lines.
The installation of IT/COMM links between Alternative A and the LFTRC Alternatives 2, 3, or 4 has the potential to result in adverse effects from excavation and soil removal to two historic properties, including one NRHP-eligible archaeological site (see Table 6.1.2-14) and one NRHP-eligible structure (North Field). Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the remaining areas. No TCPs would be directly affected by the construction of the IT/COMM links.

No direct or indirect adverse effects are anticipated to occur due to operation of the IT/COMM utilities as these lines would be buried and there would be no change in use and no effects to the setting.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. To the degree possible, impacts to historic properties and other resources of cultural importance would be avoided during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, potential minimization and mitigation measures may include data recovery and monitoring during construction. However, final mitigation will be determined after completion of the consultation process outlined in the PA. With the implementation of these measures and processes as outlined in the 2011 PA, additive impacts associated with IT/COMM would be reduced to a level below significance.

Finegayan/South Finegayan Cantonment/Family Housing Alternative B with any NAVMAG LFTRC Alternative (Alternatives 2, 3, or 4)

Adverse effects to historic properties under NHPA and impacts to other cultural resources of cultural importance resulting from the implementation of Alternative B and Alternatives 2, 3 or 4 would be equal to the combined effects and impacts of each as discussed in Chapters 4 and 5. Additional effects and impacts could also result from the construction of the IT/COMM links for these alternatives. The PDIA for the IT/COMM lines for these site combinations would be similar to those described above for Alternative A and Alternatives 2, 3, or 4. The installation of IT/COMM links between the Alternative B and the LFTRC Alternatives 2, 3, or 4 has the potential to result in adverse effects from excavation and soil removal to two historic properties—one NRHP-eligible archaeological site (see Table 6.1.2-14) and one NRHP-eligible structure (North Field). Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the remaining area. No TCPs have been identified in the potential impacted areas for the IT/COMM lines.

No direct or indirect adverse effects due to operation of the IT/COMM utilities would occur as these lines would be buried and there would be no change in use, and no effects to the setting.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. To the degree possible, impacts to historic properties and other resources of cultural importance would be avoided during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, potential minimization and mitigation measures may include data recovery and monitoring during construction. However, final mitigation will be determined after completion of the consultation process outlined in the PA. With the implementation of these measures and processes as outlined in the 2011 PA, additive impacts associated with IT/COMM would be reduced to a level below significance.
Ground Transportation

Finegayan Cantonment/Family Housing Alternative A with any NAVMAG LFTRC Alternative (Alternatives 2, 3, or 4)

Alternative A was modeled with Alternative 5 (Section 3.12.1). Pairing Alternative A with Alternative 2, 3, or 4 may result in a slight increase in vehicles (less than 5%) on roadway segments and at intersections that comprise the most direct route between the Alternative A Main Gate and the Alternative 2, 3, or 4 gates, as well as a slight decrease in vehicles on roadway segments and at intersections that comprise the most direct route between the modeled combination Alternative A Main Gate and the Alternative 5 gate. This minimal incremental increase or decrease in traffic volumes would not adversely affect LOS on roadways or at intersections along the route.

Roadway Segment Operations. Impacts and potential mitigation measures for all off-base (external) roadway segments would be the same as those identified in Section 6.1.2.1 (see Table 6.1.2-6). Significant impacts were identified on eight roadway segments. Potential mitigation measures would be feasible at all locations and could reduce the identified significant impacts to less than significant levels. The detailed results of the roadway segment analysis are provided in their entirety in Appendix F.

Intersection Operations. Impacts and potential mitigation measures for all intersections would be the same as those identified in Section 6.1.2.1 (see Table 6.1.2-6). Significant impacts were identified at nine intersections. Potential mitigation measures would be feasible at all locations and could reduce the identified significant impacts to less than significant levels. The detailed results of the intersection analysis are provided in its entirety in Appendix F.

Transit Conditions. Transit conditions under Alternative A with Alternative 2, 3, or 4, would be the same as those described in Section 6.1.2.1 for Alternative A with Alternative 1.

Pedestrian and Bicycle Conditions. Pedestrian and bicycle conditions under Alternative A with Alternative 5 would be the same as those described in Section 6.1.2.1 for Alternative A with Alternative 1.

Finegayan/South Finegayan Cantonment/Family Housing Alternative B with any NAVMAG LFTRC Alternative (Alternatives 2, 3, or 4)

Alternative B was modeled with Alternative 2 or 4 (see Section 3.12.1). Pairing Alternative B with Alternative 3 may result in a slight increase in vehicles (less than 5%) on roadway segments and at intersections along the most direct route between the Alternative B Main Gate and the Alternative 3 gate, and a slight decrease in vehicles on roadway segments and at intersections along the most direct route between the modeled combination of Alternative B Main Gate and the Alternative 2 or 4 gates (see Figure 6.1.2-2). This minimal incremental increase or decrease in traffic volumes would not adversely affect LOS on roadways or at intersections along the route.

Roadway Segment Operations. Impacts and potential mitigation measures for all off-base (external) roadway segments under Alternative B with Alternative 2, 3, or 4 would be the same as those identified in Section 6.1.2.1 (see Table 6.1.2-7 and Table 6.1.2-12) for Alternative B with Alternative 1. Significant impacts were identified on 10 roadway segments and potential mitigation measures were identified for 8 roadway segments. Potential mitigation measures have not been identified for these two locations. The detailed results of the roadway segment analysis are provided in their entirety in Appendix F.

Intersection Operations. Impacts and potential mitigation measures for all study intersections under Alternative B with Alternative 2, 3, or 4 would be the same as those identified in Section 6.1.2.1 (see Table 6.1.2-7) for Alternative B with Alternative 1. Significant impacts were identified at 11 intersections.
with potential mitigation measures identified for 9 intersections; potential mitigation measures have not been identified for the remaining 2 intersections. The detailed results of the intersection analysis are provided in their entirety in Appendix F.

Transit Conditions. Transit conditions under Alternative B with Alternative 2, 3, or 4 would be the same as those described in Section 6.1.2.1 for Alternative A with Alternative 1.

Pedestrian and Bicycle Conditions. Pedestrian and bicycle conditions under Alternative B with Alternative 2, 3, or 4 would be the same as those described in Section 6.1.2.1 for Alternative A with Alternative 1.

Public Health and Safety

The potential for traffic incidents is the primary health and safety issue with potential for creating additive impacts from implementing a specific cantonment/family housing alternative with a specific LFTRC alternative. The driving distances between the Alternative A area and the proposed NAVMAG LFTRC alternatives (Alternatives 2, 3, and 4) is approximately 22.3 miles (35.9 km) to Alternative 2, and 27.9 miles (44.9 km) to Alternatives 3 and 4. Vehicles would use Routes 1 and 3 to commute between the Alternative A or B areas and Alternative 1, while Routes 3, 4, 10, and 16, as well as a new roadway in Dandan, would be used to access Alternatives 3 and 4.

Five high-crash frequency intersections (intersections of Routes 1/3, Routes 1/14A, Routes 1/10A, Routes 1/14, and Routes 1/30) are situated along the travel route between the Alternative A and Alternative B area and Alternative 2. These intersections are primarily in the central portion of Guam in the highest developed area of the island, within the communities of Hagåtña and Tamuning. Two high-crash frequency intersections (intersection of Routes 1/3 and Routes 8/10/16) are situated along the travel route between the Alternative A and Alternative B area and the Alternatives 3 and 4. In an effort to improve vehicle safety at the intersection of Routes 8/10/16, traffic improvements were completed in 2012 that included the installation of a new traffic signal system that reduced congestion and channelized traffic. The travel distance between the Alternative A or Alternative B area and the NAVMAG alternatives is relatively long, and several high-frequency crash intersections are situated along the travel routes (resulting in a higher potential for being involved in a traffic incident or to be delayed because of traffic incidents). However, a less-than-significant additive impact on public health and safety is anticipated to occur since the additional vehicles traveling between the main cantonment and LFTRC would be an insignificant portion of total vehicles on these roadways.

6.1.2.3 Finegayan Cantonment/Family Housing Alternative A or B with NWF LFTRC Alternative 5

Air Quality

The combined air quality impacts would be the same as those described in Section 6.1.2.1. The combined construction island-wide emissions impacts, summarized in Table 6.1.2-1, would be less than significant as a result of this combined alternative.

Terrestrial Biological Resources

Finegayan Cantonment/Family Housing Alternative A with NWF LFTRC Alternative 5

The additive impacts of implementing Cantonment/Family Housing Alternative A, LFTRC Alternative 5, and the IT/COMM infrastructure are provided in Table 6.1.2-15. Overall, approximately 1,254 acres (508 ha) of limestone forest, or 7% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 1,624 acres (657 ha) of Overlay Refuge lands, or 7% of the total Overlay Refuge currently present on Guam, would be disturbed. The proposed IT/COMM alignment contributes
little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

**Cultural Resources**

**Finegayan Cantonment/Family Housing Alternative A with NWF LFTRC Alternative 5**

Adverse effects to historic properties under NHPA and impacts to other cultural resources of cultural importance resulting from the implementation of Alternatives A and 5 would be equal to the combined effects and impacts of each as discussed in Chapters 4 and 5. Additional effects and impacts could also result from the construction of the IT/COMM links for these alternatives. Construction for the IT/COMM lines for Alternative A and Alternative 5 would occur along Routes 1, 2A, 3, 3A, 4, 4A, 5, 9, 10, 15, and 17. In general, IT/COMM lines would follow existing roads; however, additional lines would be constructed at AAFB and from AAFB to Finegayan. Approximately 44% of these areas have been previously surveyed (Davis 1983; April 1984; Kurashina et al. 1988; Moore et al. 1988; Amesbury and Moore 1989; Moore and Amesbury 1989; Russell and Guerrero 1991; Henry et al. 1996, 1999; Hunter-Anderson 1994; Reinman and Nees 1998; Olmo et al. 2000; Hunter-Anderson et al. 2001; Allen et al. 2002; Hunter-Anderson 2002; Hunter-Anderson and Moore 2002, 2003; Dixon et al. 2004, 2011a, 2011b, 2015a, 2015b; Yee et al. 2004, DeFant and Guerrero 2006; Grant et al. 2007; Church et al. 2009; Athens 2009; Welch 2010; Dixon and Walker 2011; DeFant 2013). As not all of the routes have been surveyed, a literature review of previous surveys and sites located within the construction corridor was undertaken and the likelihood of finding buried cultural resources within PDIA for the IT/COMM lines corridor was assessed based on the level of disturbance, the proximity of known sites, and historic land use (Dixon et al. 2014). Within the PDIA for the IT/COMM lines, approximately 1% of Route 1, 57% of Route 2A,
100% of Route 3, 49% of Route 3A, 1% of Route 4, 100% of Route 4A, 16% of Route 5, 64% of Route 9, none of Route 10, 59% of Route 15, and 1% of Route 17 have been surveyed.

Table 6.1.2-17 lists 17 known archaeological sites within the IT/COMM lines PDIA. Five of the sites, two artifact scatters, a Japanese defensive complex, a historic encampment, and portions of NWF, are eligible for inclusion on the NRHP. Twelve archaeological sites are not eligible for listing in the NRHP. The literature review indicated that there are also areas that were not previously surveyed that have potential for buried cultural resources along Routes 1, 5, 15, and 17.

</table>
One structure eligible for listing in the NRHP, North Field, is located within the potential impacted area. No TCPs have been identified in the potential impacted areas for the IT/COMM lines.

The installation of IT/COMM links between Alternative A and the LFTRC Alternative 5 has the potential to result in adverse effects from excavation and soil removal to six historic properties, including five NRHP-eligible archaeological site (see Table 6.1.2-17) and one NRHP-eligible structure (North Field). Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the remaining areas. No TCPs would be directly affected by the construction of the IT/COMM links.

No direct or indirect adverse effects due to operation of the IT/COMM utilities would occur as these lines would be buried and there would be no change in use, and no effects to the setting.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. To the degree possible, impacts to historic properties and other resources of cultural importance would be avoided during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, potential minimization and mitigation measures may include data recovery and monitoring during construction. However, final mitigation will be determined after completion of the consultation process outlined in the PA. With the implementation of these measures and processes as outlined in the 2011 PA, additive impacts associated with IT/COMM would be reduced to a level below significance.

**Finegayan/South Finegayan Cantonment/Family Housing Alternative B with NWF LFTRC Alternative 5**

Adverse effects to historic properties under NHPA and impacts to other cultural resources of cultural importance resulting from the implementation of Alternatives B and 5 would be equal to the combined effects and impacts of each as discussed in Chapters 4 and 5. Additional effects and impacts could also result from the construction of the IT/COMM links for these alternatives. The PDIA for the IT/COMM lines would be similar to those described for Alternative A and Alternative 5. The installation of IT/COMM links between Alternative B and the LFTRC Alternative 5 has the potential to result in adverse effects from excavation and soil removal to six historic properties, including five NRHP-eligible archaeological site (see Table 6.1.2-17) and one NRHP-eligible structure (North Field). Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-
eligible sites in the remaining areas. No TCPs would be affected by the construction of the IT/COMM links.

No direct or indirect adverse effects due to operation of the IT/COMM utilities would occur as these lines would be buried and there would be no change in use, and no effects to the setting.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. To the degree possible, impacts to historic properties and other resources of cultural importance would be avoided during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, potential minimization and mitigation measures may include data recovery and monitoring during construction. However, final mitigation will be determined after completion of the consultation process outlined in the PA. With the implementation of these measures and processes as outlined in the 2011 PA, additive impacts associated with IT/COMM would be reduced to a level below significance.

Ground Transportation

Finegayan Cantonment/Family Housing Alternative A with NWF LFTRC Alternative 5

Alternative A was modeled with Alternative 5 (Section 3.12.1).

Roadway Segment Operations. Impacts and potential mitigation measures for all off-base (external) roadway segments under Alternative A with Alternative 5 would be the same as those identified in Section 6.1.2.1 for Alternative A with Alternative 1. Potential mitigation measures were identified for all impacted roadway segments, and if implemented, could reduce the impacts to less than significant levels. Significant impacts were identified on eight roadway segments. The detailed results of the roadway segment analysis are provided in their entirety in Appendix F.

Intersection Operations. Impacts and potential mitigation measures for all intersections under Alternative A with Alternative 5 would be the same as those identified in Section 6.1.2.1 (see Table 6.1.2-6) for Alternative A with Alternative 1. Potential mitigation measures were identified for all impacted intersections, and if implemented, could reduce the impacts to less than significant levels. Significant impacts were identified at nine intersections. The detailed results of the intersection analysis are provided in its entirety in Appendix F.

Transit Conditions. Transit conditions under Alternative A with Alternative 5 would be the same as those described in Section 6.1.2.1 for Alternative A with Alternative 1.

Pedestrian and Bicycle Conditions. Pedestrian and bicycle conditions under Alternative A with Alternative 5 would be the same as those described in Section 6.1.2.1 for Alternative A with Alternative 1.

Finegayan/South Finegayan Cantonment/Family Housing Alternative B with NWF LFTRC Alternative 5

Alternative B was modeled with Alternative 2 or 4 (Section 3.12.1). Pairing Alternative B with Alternative 5 may result in a slight increase (less than 5%) in vehicles on roadway segments and at intersections along the most direct route between the Alternative B Main Gate and the Alternative 5 gate, and a slight decrease in vehicles on roadway segments and at intersections along the most direct route between the modeled combination, Alternative B Main Gate and the Alternative 2 or 4 gate (see Figure 6.1.2-2). This minimal incremental increase or decrease in traffic volumes would not adversely affect LOS on roadways or at intersections along the route.
Roadway Segment Operations. Impacts and potential mitigation measures for all off-base (external) roadway segments would be the same as those identified in Section 6.1.2.1. Significant impacts were identified on 10 roadway segments. Potential mitigation measures were identified for 8 roadway segments and were not identified for 2 segments. The detailed results of the roadway segment analysis are provided in their entirety in Appendix F.

Intersection Operations. Impacts and potential mitigation measures for all intersections would be the same as those identified in Section 6.1.2.1 (see Table 6.1.2-7). Significant impacts were identified at 11 intersections. Potential mitigation measures were identified for 9 intersections and were not identified for 2 intersections. The detailed results of the intersection analysis are provided in its entirety in Appendix F.

Transit Conditions. Transit conditions under Alternative B with Alternative 5 would be the same as those described in Section 6.1.2.1 for Alternative A with Alternative 1.

Pedestrian and Bicycle Conditions. Pedestrian and bicycle conditions under Alternative B with Alternative 5 would be the same as those described in Section 6.1.2.1 for Alternative A with Alternative 1.

Public Health and Safety

The potential for traffic incidents is the primary health and safety issue with potential for having additive impacts from implementing a specific cantonment/family housing alternative with a specific LFTRC alternative. The driving distance between the Alternative A or Alternative B area and the proposed NWF LFTRC alternative (Alternative 5) is approximately 4.4 miles (7.1 km). Vehicles would use Routes 3 and 3A to commute between either of these cantonment/family housing areas and Alternative 5. No high-crash frequency intersections are situated along this travel route. The travel distance between Alternative A or B and Alternative 5 is relatively short, and no high-frequency crash intersections are situated along this travel route. Therefore, no significant additive traffic impacts are anticipated.

6.1.2.4 AAFB Cantonment/Family Housing Alternative C with Route 15 LFTRC Alternative 1

Air Quality

The combined air quality impacts would be similar to those described in Section 6.1.2.1. The combined construction island-wide emissions, summarized in Table 6.1.2-18, would be below the significance criterion of 250 tpy for criteria pollutants resulting in less than significant as a result of this combined alternative.

Table 6.1.2-18. AAFB Cantonment/Family Housing (Alternative C) with Route 15 LFTRC (Alternative 1, 2, 3, 4, or 5) Annual Construction Emissions (2016-2022)

Terrestrial Biological Resources

The additive impacts of implementing Cantonment/Family Housing Alternative C, LFTRC Alternative 1, and the IT/COMM infrastructure are provided in Table 6.1.2-19. Overall, approximately 1,458 acres (590 ha) of limestone forest, or 8% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 972 acres (394 ha) of Overlay Refuge lands, or 4% of the total Overlay Refuge currently present on Guam, would be disturbed. The proposed IT/COMM alignment contributes little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Cultural Resources

Adverse effects to historic properties under NHPA and impacts to other cultural resources of cultural importance resulting from the implementation of Alternatives C and 1 would be equal to the combined effects and impacts of each as discussed in Chapters 4 and 5. Additional effects and impacts could also result from the construction of the IT/COMM links for these alternatives. Construction for the IT/COMM lines for Alternative C and Alternative 1 would occur along Routes 1, 2A, 3, 3A, 4, 4A, 5, 9, 10, 15, and 17. In general, IT/COMM lines would follow existing roads; however, additional lines would be constructed at AAFB and from AAFB to Finegayan. Approximately 42% of these areas have been previously surveyed (Davis 1986; April 1984; Kurashina et al. 1987; Haun 1988; Kurashina et al. 1988; Moore et al. 1988; Amesbury and Moore 1989; Moore and Amesbury 1989; Highness and Haun 1990; Russell and Guerrero 1991; Tuggle 1993; Henry et al. 1996, 1999; Hunter-Anderson 1994; Liston 1996; Reinman and Nees 1998; Olmo et al. 2000; Hunter-Anderson et al. 2001; Allen et al. 2002; Hunter-Anderson 2002; Hunter-Anderson and Moore 2002, 2003; Dixon et al. 2004, 2011a, 2011b, 2015a,
2015b; Yee et al. 2004; DeFant and Guerrero 2006; Grant et al. 2007; Church et al. 2009; Athens 2009; Welch 2010; Dixon and Walker 2011; DeFant 2013). As not all of the routes have been surveyed, a literature review of previous surveys and sites located within the construction corridor was undertaken and the likelihood of finding buried cultural resources within PDIA for the IT/COMM lines corridor was assessed based on the level of disturbance, the proximity of known sites, and historic land use (Dixon et al. 2014). Within the PDIA for the IT/COMM lines, approximately 0.1% of Route 1, 57% of Route 2A, 100% of Route 3, 67% of Route 3A, 4% of Route 4, 100% of Route 4A, 16% of Route 5, 71% of Route 9, none of Route 10, 54% of Route 15, and 1% of Route 17 have been surveyed.

Table 6.1.2-20 lists 13 known archaeological sites within the IT/COMM lines PDIA. Three of the sites, including remnants of an encampment, a Latte Period artifact scatter, and portions NWF, are eligible to the NRHP. Ten archaeological sites are not eligible for listing in the NRHP. The literature review indicated that there are also areas that were not previously surveyed that have potential for buried cultural resources along Routes 1, 5, 15, and 17.

Legend: GHPI = Guam Historic Properties Inventory; NRHP = National Register of Historic Places; NA = not applicable; NRHP criterion A = eligible because they are associated with events that have made a significant contribution to the broad pattern of history, criterion D = eligible for potential to yield information important in prehistory or history.

Notes: †Not all sites recorded within the project areas have received official GHPI numbers, although they have been documented as part of previous surveys. *From Welch 2009 (Map no. 36, 235, 377) and Welch 2010 (Map no. 1066). **Revised to match Guam GHPI forms dated May 28, 2014. ***The Guam SHPO concurs with this recommendation (Guam SHPO correspondence dated July 2 and September 17, 2014 [RC2013-0853]).
One structure eligible for listing in the NRHP, North Field, is located within the potential impacted area. No TCPs have been identified in the potential impacted areas for the IT/COMM lines.

The installation of IT/COMM links between Alternative C and the LFTRC Alternative 1 has the potential to result in adverse effects from excavation and soil removal to four historic properties--three NRHP-eligible archaeological sites (see Table 6.1.2-20) and one NRHP-eligible structure (North Field). Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the remaining areas. No TCPs would be affected by the construction of the IT/COMM links.

No direct or indirect adverse effects due to operation of the IT/COMM utilities would occur as these lines would be buried and there would be no change in use, and no effects to the setting.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. To the degree possible, impacts to historic properties and other resources of cultural importance would be avoided during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, potential minimization and mitigation measures may include data recovery and monitoring during construction. However, final mitigation will be determined after completion of the consultation process outlined in the PA. With the implementation of these measures and processes as outlined in the 2011 PA, additive impacts associated with IT/COMM would be reduced to a level below significance.

**Ground Transportation**

The travel demand modeling methodology for the combination of alternatives was defined and directed by the DoD and the FHWA to provide detailed off-base (external) roadway and intersection analysis for one representative pairing (the modeled combination) for a cantonment/family housing alternative and LFTRC site alternative. The modeled combination for Alternative C involved a pairing with Alternative 2 or 4 (see Section 3.12.1). Modeling results for this scenario indicate that weekday a.m. peak hour vehicle traffic related to the proposed action is generated solely by operations at the cantonment/family housing area. LFTRC-related traffic would occur prior to the weekday a.m. peak hour (8:00 a.m.) and may coincide with the weekday p.m. peak hour (4:30 p.m. to 5:30 p.m.) (see Section 5.1.12).

Operations of the LFTRC would increase traffic on the off-base (external) roadway segments and intersections that comprise the most direct route between the main cantonment gate and the LFTRC gates by approximately 38 vehicles (measured in passenger car equivalents) (see Table 5.1.12-2). LFTRC-related traffic represents an insubstantial amount of traffic (less than 5%) along the route. This minimal incremental increase in traffic volumes would not adversely affect LOS on roadways or at intersections along the route. The relative contribution from LFTRC traffic to the off-base (external) roadway segment and intersection impacts of each cantonment/family housing alternative would be minimal and would not vary appreciably with any LFTRC alternative (Alternative 1, 2, 3, 4, and 5). Therefore, the impacts to the off-base (external) roadway segments and intersections would be essentially the same for Alternative C with Alternative 1, Alternative C with Alternative 2, 3, or 4, and Alternative C with Alternative 5. A qualitative discussion of the potential effects of LFTRC-related traffic is provided for each combination.
Pairing Alternative C with Alternative 1 may result in a slight increase in vehicles (less than 5%) on roadway segments and at intersections that comprise the most direct route between the Alternative C Main Gate and the Alternative 1 gate, and a slight decrease in vehicles compared to the modeled combination, Alternative C Main Gate and the Alternative 2 or 4 gates (Figure 6.1.2-3). This minimal incremental increase or decrease in traffic volumes would not adversely affect LOS on roadways or at intersections along the route.

The impacts to off-base (external) roadway segments and intersections are summarized in Table 6.1.2-21.

**Legend:** NA indicates not applicable. SI indicates significant impact. SI-M indicates significant but may be mitigated impact.

**Note:** * Includes impacts to roadway segments in at least one direction during one (or both) weekday a.m. or p.m. peak hours.

**Roadway Segment Operations.** A capacity analysis was conducted to determine potential impacts to the off-base (external) roadway network during weekday a.m. and p.m. peak hours. The v/c ratio and LOS for each study roadway segment was compared to the baseline conditions to determine if any significant impacts would occur. The detailed results of the roadway segment analysis are provided in their entirety in Appendix F. The addition of traffic generated by the proposed action may result in a potentially significant impact on six study roadway segments in at least one direction during the weekday a.m. and/or weekday p.m. peak hours.
Figure 6.1.2-3
Travel Routes from Andersen Air Force Base Cantonment/Housing (Alternative C) to the LFTRC Alternatives

Source: NAVFAC Pacific 2013
• **Route 1, from Route 29 to Chalan Lajuna.** This study roadway segment currently operates at acceptable LOS C with a v/c ratio of 0.78 in the northbound/eastbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would operate at acceptable LOS D with a v/c ratio of 0.86 in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study roadway segment would degrade to operate at unacceptable LOS F with a v/c ratio of 1.02. Therefore, the proposed action would result in a significant impact in the northbound/eastbound direction on this study roadway segment during the weekday p.m. peak hour.

• **Route 1, from Route 34 to Route 16.** This study roadway segment currently operates at acceptable LOS E with a v/c ratio of 0.96 in the northbound/eastbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would operate at acceptable LOS E with a v/c ratio of 0.97 in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study roadway segment would degrade to unacceptable LOS F with a v/c ratio of 1.01. Therefore, the proposed action would result in a significant impact in the northbound/eastbound direction on this study roadway segment during the weekday p.m. peak hour.

• **Route 3, from Finegayan Main Gate to Finegayan Residential Gate.** This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.09 in the southbound/westbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.24 in the southbound/westbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.33. The proposed action would increase traffic on this study roadway segment by approximately 70 vehicles during the weekday p.m. peak hour. This 7.1% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact on this study roadway segment in the southbound/westbound direction during the weekday a.m. peak hour.

• **Route 3, from Finegayan Residential Gate to Route 28.** This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.23 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would continue to operate at LOS F with a v/c ratio of 1.36 in the southbound/westbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.45. The proposed action would increase the traffic on this study roadway segment by approximately 67 vehicles during the weekday a.m. peak hour. This 6.3% increase in traffic is greater than the 5.0% threshold of significance. During the weekday p.m. peak hour this study roadway segment currently operates at acceptable LOS D with a v/c ratio of 0.81 in the northbound/eastbound direction. This study roadway segment would operate at acceptable LOS E in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study roadway segment would degrade to unacceptable LOS F with a v/c ratio of 1.04. Therefore, the proposed action would result in a significant impact on this study roadway segment during the weekday p.m. peak hour.
segment in the southbound/westbound directions during the weekday a.m. peak hour and in the northbound/eastbound direction during the weekday p.m. peak hour.

- **Route 15, from Route 26 to Barrigada South Gate.** This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.05 in the northbound/eastbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.06 in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 118. The proposed action would increase traffic on this study roadway segment by approximately 90 vehicles during the weekday p.m. peak hour. This 10.6% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact in the northbound/eastbound direction on this study roadway segment during the weekday a.m. peak hour.

- **Route 15, from Barrigada South Gate to Route 10.** This study roadway segment currently operates at acceptable LOS D with a v/c ratio of 0.90 in the northbound/eastbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.02 in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.14. The proposed action would increase traffic on this study roadway segment by approximately 88 vehicles during the weekday a.m. peak hour. This 10.3% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact in the northbound/eastbound direction on this study roadway segment during the weekday a.m. peak hour.

Significant impacts were identified for all impacted roadway segments. Potential mitigation measures for the impacted roadway segments would be similar in scope and scale to those identified in Section 6.1.2.1. However, the exact details of the improvements would require further evaluations and technical studies to determine their feasibility. The final list of implementable mitigation measures will be dependent on the selected alternative or combination of alternatives, and based on project-level technical studies to be conducted after the alternative or combination of alternatives is selected. FHWA will conduct all NEPA documentation efforts and any associated resource consultations as specific mitigation measures are proposed.

**Intersection Operations.** Intersection analysis was conducted to determine potential impacts to the off-base (external) intersections during weekday a.m. and p.m. peak hours. The LOS for each study intersection is compared to the baseline conditions to determine if any significant impacts would occur. An impact summary is provided in Table 6.1.2-21. The detailed results of the intersection analysis are provided in their entirety in Appendix F.

The addition of traffic generated by the proposed action would potentially result in a significant impact at 11 study intersections during the weekday a.m. and/or weekday p.m. peak hours.

- **Route 3 / 9 / Chalan Santa Anita.** This two-way stop-controlled study intersection currently operates at acceptable LOS C with 21.9 seconds of delay and would operate at acceptable LOS E with 37.7 seconds of delay during the weekday a.m. peak hour under Existing Conditions and
Year 2030 Baseline Conditions, respectively. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study intersection would degrade to unacceptable LOS F with 134.6 seconds of delay. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour.

- **Route 3 / Royal Palm Drive.** This two-way stop-controlled study intersection currently operates at acceptable LOS C with 16.3 seconds of delay and would operate at acceptable LOS E with 36.4 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study intersection would degrade to unacceptable LOS F with 50.6 seconds of delay. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour.

- **Route 15 / Chalan Lajuna.** This two-way stop-controlled study intersection currently operates at acceptable LOS D with 30.7 seconds of delay and LOS C with 23.9 seconds of delay during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions. This intersection would operate at unacceptable LOS F with 75.8 and 82.6 seconds of delay during the weekday a.m. and p.m. peak hours, respectively, under Year 2030 Baseline Conditions. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study intersection would continue to operate at unacceptable LOS F with 119.9 and 166.3 seconds of delay during the weekday a.m. and p.m. peak hours, respectively. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. and p.m. peak hours.

- **Route 1 / Route 3.** This signalized study intersection currently operates at LOS F and would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay and the proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour.

- **Route 1 / Route 27.** This signalized study intersection currently operates at acceptable LOS E with 70.3 seconds of delay and would operate at unacceptable LOS F with 118.3 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study intersection would continue to operate at unacceptable LOS F with 123.6 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour.

- **Route 1 / Route 26.** This signalized study intersection currently operates at acceptable LOS C with 27.9 seconds of delay and would operate at unacceptable LOS F with 87.6 seconds of delay during the weekday p.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study intersection would continue to operate at unacceptable LOS F with 95.7 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday p.m. peak hour.
• Route 16 / Route 27. This signalized study intersection currently operates at acceptable LOS D with 50.1 seconds of delay and acceptable LOS E with 71.2 seconds of delay during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions. This signalized study intersection would operate at unacceptable LOS F with greater than 180.0 seconds of delay and 154.7 seconds of delay during the weekday a.m. and p.m. peak hours, respectively under Year 2030 Baseline Conditions. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay and 161.9 seconds of delay during the weekday a.m. and p.m. peak hours, respectively. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. and p.m. peak hours.

• Route 16 / Route 10A. This signalized study intersection currently operates at unacceptable LOS F and would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour.

• Route 15 / Route 26. This two-way stop-controlled study intersection currently operates at unacceptable LOS F with 62.1 seconds of delay and 147.3 seconds of delay during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions. This intersection would continue to operate at unacceptable LOS F with greater than 145.2 seconds of delay and greater than 180.0 seconds of delay during the weekday a.m. and p.m. peak hours, respectively under Year 2030 Baseline Conditions. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday a.m. and p.m. peak hours. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. and p.m. peak hours.

• Route 1 / Route 14A. This signalized study intersection currently operates at unacceptable LOS F with 156.1 seconds of delay during the weekday p.m. peak hour under Existing Conditions. This study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour.

• Route 1 / Route 10A. This signalized study intersection currently operates at acceptable LOS E with 62.6 seconds of delay and would operate at unacceptable LOS F with 139.3 seconds of delay during the weekday p.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 AAFB Cantonment/Family Housing (Alternative C) Conditions, this study intersection would continue to operate at unacceptable LOS F with 141.6 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing
intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday p.m. peak hour.

Although significant impacts would occur at all intersections, potential mitigation measures have not been identified. Potential mitigation measures for the impacted intersections would be similar in scope and scale to those identified in Section 6.1.2.1. However, the exact details of the improvements would require further evaluations and technical studies to determine their feasibility. The final list of implementable mitigation measures will be dependent on the selected alternative or combination of alternatives and based on project-level technical studies, to be conducted after the alternative or combination of alternatives is selected. FHWA will conduct all NEPA documentation efforts and any associated resource consultations as specific mitigation measures are proposed.

**Transit Conditions.** Transit conditions under Alternative C with Alternative 1 would be similar to those described in Section 6.1.2.1 for Alternative A with Alternative 1.

**Pedestrian and Bicycle Conditions.** Pedestrian and bicycle conditions under Alternative C with Alternative 1 would be similar to those described in Section 6.1.2.1 for Alternative A with Alternative 1.

**Public Health and Safety**

The potential for traffic incidents is the primary health and safety issue with potential for creating additive impacts from implementing a specific cantonment/family housing alternative with a specific LFTRC alternative. The driving distance between the proposed AAFB Cantonment/Family Housing (Alternative C) area and Alternative 1 is approximately 5.5 miles (8.8 km). Vehicles would use Route 9 to commute between the Alternative C area and Alternative 1. The travel distance between the Alternative C area and Alternative 1 is relatively short, and no high-frequency crash intersections are situated along the travel route. Therefore, no significant additive traffic impacts are anticipated.

6.1.2.5 AAFB Cantonment/Family Housing Alternative C with any NAVMAG LFTRC Alternative (Alternatives 2, 3, or 4)

**Air Quality**

The combined air quality impacts would be the same as those described in Section 6.1.2.4. The combined construction island-wide emissions, summarized in Table 6.1.2-18, would be less than significant as a result of these combined alternatives.

**Terrestrial Biological Resources**

**AAFB Cantonment/Family Housing (Alternative C) with NAVMAG (North/South) LFTRC (Alternative 2)**

The additive impacts of implementing Cantonment/Family Housing Alternative C, LFTRC Alternative 2, and the IT/COMM infrastructure are provided in Table 6.1.2-22. Overall, approximately 1,222 acres (495 ha) of limestone forest, or 6% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 972 acres (393 ha) of Overlay Refuge lands, or 4% of the total Overlay Refuge currently present on Guam, would be disturbed. The majority (96%) of the impacts to terrestrial biological resources would occur under Alternative C, with 1,177 acres (476 ha) of limestone forest disturbed. The proposed IT/COMM alignment contributes little to the overall potential impact to terrestrial biological resources under this scenario relative to the other two components. Additive impacts to terrestrial biological resources would be less than significant.

(2) Only species for which there would be a significant impact.

AAFB Cantonment/Family Housing Alternative C with NAVMAG (North/South) LFTRC Alternative 3

The additive impacts of implementing Cantonment/Family Housing Alternative C, LFTRC Alternative 3, and the IT/COMM infrastructure are provided in Table 6.1.2-23. Overall, approximately 1,372 acres (555 ha) of limestone forest, or 7% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 1,247 acres (505 ha) of Overlay Refuge lands, or 6% of the total Overlay Refuge currently present on Guam, would be disturbed. The majority of the impacts to terrestrial biological resources would occur under Alternative C, with 1,177 acres (476 ha) of limestone forest disturbed. The proposed IT/COMM alignment contributes little to the overall potential impact to terrestrial biological resources relative to the other components under this scenario. Additive impacts to terrestrial biological resources would be less than significant.

**AAFB Cantonment/Family Housing Alternative C with NAVMAG (L-Shaped) LFTRC Alternative 4**

The additive impacts of implementing Cantonment/Housing Alternative C, LFTRC Alternative 4, and the IT/COMM infrastructure are provided in Table 6.1.2-24. Overall, approximately 1,333 acres (539 ha) of limestone forest, or 7% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 1,191 acres (482 ha) of Overlay Refuge lands, or 6% of the total Overlay Refuge currently present on Guam, would be disturbed. The proposed IT/COMM alignment contributes little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Cultural Resources

Adverse effects to historic properties under NHPA and impacts to other cultural resources of cultural importance resulting from the implementation of Alternative C and 2, 3, or 4 would be equal to the combined effects and impacts of each as discussed in Chapters 4 and 5. Additional effects and impacts could also result from the construction of the IT/COMM links for these alternatives. Construction for the IT/COMM lines for Alternative C and Alternatives 2, 3, or 4 would occur along Routes 1, 2A, 3, 3A, 4, 4A, 5, 8, 9, 10, 15, 16, and 17. In general, IT/COMM lines would follow existing roads; however, additional lines would be constructed at AAFB and from AAFB to Finegayan. Approximately 50% of these areas have been previously surveyed (Thomas and Price 1979; Davis 1983; April 1984; Kurashina \textit{et al.} 1987; Haun 1988; Kurashina \textit{et al.} 1988; Moore \textit{et al.} 1988; Amesbury and Moore 1989; Moore and Amesbury 1989; Highness and Haun 1990; Amesbury \textit{et al.} 1991; Carrell 1991; Russell and Guerrero 1991; Prasad and Moore 1992; Tuggle 1993; Russell \textit{et al.} 1993; Hunter-Anderson 1994; Reinman 1995; Wells \textit{et al.} 1995; Workman and Haun 1995; Liston 1996; Hunter-Anderson \textit{et al.} 1995, 1997; Reinman and Nees 1998; Olmo \textit{et al.} 2000; Hunter-Anderson \textit{et al.} 2001; Henry \textit{et al.} 1999; Allen \textit{et al.} 2002; Hunter-Anderson 2002, 2004; Hunter-Anderson and Moore 2002, 2003; Dixon \textit{et al.} 1999, 2004, 2011a, 2011b, 2015a, 2015b; Yee \textit{et al.} 2004; DeFant and Guerrero 2006; Grant \textit{et al.} 2007; Church \textit{et al.} 2009; Athens 2009; Welch 2010; Dixon and Walker 2011; DeFant 2013). As not all of the routes have been surveyed, a literature review of previous surveys and sites located within the construction corridor was undertaken and the likelihood of finding buried cultural resources within PDIA for the IT/COMM lines corridor was assessed based on the level of disturbance, the proximity of known sites, and historic land...
use (Dixon et al. 2014). Within the PDIA for the IT/COMM lines, approximately 39% of Route 1, 61% of Route 2A, 100% of Route 3, 67% of Route 3A, 11% of Route 4, 100% of Route 4A, 16% of Route 5, 90% of Route 8, 71% of Route 9, none of Route 10, 59% of Route 15, 55% of Route 16, and 2% of Route 17 have been surveyed.

Table 6.1.2-25 lists 14 known archaeological sites within the IT/COMM lines PDIA for Alternatives 2, 3, and 4. Three of the sites, including remnants of an historic encampment, a Late Period artifact scatter, and portions of NWF, are eligible for listing in the NRHP. Eleven archaeological sites are not eligible for listing in the NRHP. The literature review indicated that there are also areas that were not previously surveyed that have potential for buried cultural resources along Routes 1, 5, 15, and 17.

Legend: GHIPI = Guam Historic Properties Inventory; NRHP = National Register of Historic Places; NA=not applicable; NRHP criterion A = eligible because they are associated with events that have made a significant contribution to the broad pattern of history, criterion D = eligible for potential to yield information important in prehistory or history.

Notes: †Not all sites recorded within the project areas have received official GHIPI numbers, although they have been documented as part of previous surveys.
**Revised to match Guam GHIPI forms dated May 28, 2014.
***The Guam SHPO concurs with this recommendation (Guam SHPO correspondence dated July 2 and September 17, 2014 [RC2013-0853]).
One structure eligible for listing in the NRHP, North Field, is located within the potential impacted area for Alternatives 2, 3, and 4. No TCPs have been identified in the potential impacted areas for the IT/COMM lines.

The installation of IT/COMM links between Alternative C and the LFTRC Alternatives 2, 3, or 4 has the potential to result in adverse effects from excavation and soil removal to four historic properties—three known NRHP-eligible archaeological sites (see Table 6.1.2-25) and one NRHP-eligible structure (North Field). Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the remaining areas. No TCPs would be directly affected by the construction of the IT/COMM links.

No direct or indirect adverse effects due to operation of the IT/COMM utilities would occur as these lines would be buried and there would be no change in use, and no effects to the setting.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. To the degree possible, impacts to historic properties and other resources of cultural importance would be avoided during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, potential minimization and mitigation measures may include data recovery and monitoring during construction. However, final mitigation will be determined after completion of the consultation process outlined in the PA. With the implementation of these measures and processes as outlined in the 2011 PA, additive impacts associated with IT/COMM would be reduced to a level below significance.

Ground Transportation

Alternative C was modeled with Alternative 2 or 4 (Section 3.12.1). Pairing Alternative C with Alternative 3 may result in a slight increase (less than 5%) in vehicles on roadway segments and at intersections that comprise the most direct route between the Alternative C Main Gate and the Alternative 3 gate, and a slight decrease in vehicles on roadway segments and at intersections that comprise the most direct route between the modeled combination, Alternative C Main Gate and the Alternative 2 or 4 gates (see Figure 6.1.2-3). This minimal incremental increase or decrease in traffic volumes would not adversely affect LOS on roadways or at intersections along the route.

Although significant impacts would occur at all locations, potential mitigation measures have not been identified for any of the impacted roadway segments or intersections. Potential mitigation measures for would be similar in scope and scale to those identified in Section 6.1.2.1. However, the exact details of the improvements would require further evaluations and technical studies to determine their feasibility. The final list of implementable mitigation measures will be dependent on the selected alternative or combination of alternatives and based on project-level technical studies, to be conducted after the alternative or combination of alternatives is selected. FHWA will conduct all NEPA documentation efforts and any associated resource consultations as specific mitigation measures are proposed.

Roadway Segment Operations. Impacts to all off-base (external) roadway segments would be the same as those identified in Section 6.1.2.4. Significant impacts were identified on six roadway segments. The detailed results of the roadway segment analysis are provided in their entirety in Appendix F.

Intersection Operations. Impacts to all intersections would be the same as those identified in Section 6.1.2.4 (see Table 6.1.2-21). Significant impacts were identified at 11 intersections. The detailed results of the intersection analysis are provided in its entirety in Appendix F.
Transit Conditions. Transit conditions under Alternative C with Alternative 2, 3, or 4 would be the same as those described in Section 6.1.2.1 for Alternative A with Alternative 1.

Pedestrian and Bicycle Conditions. Pedestrian and bicycle conditions under Alternative C with Alternative 2, 3, or 4 would be the same as those described in Section 6.1.2.1 for Alternative A with Alternative 1.

Public Health and Safety

The potential for traffic incidents is the primary health and safety issue with potential for having additive impacts from implementing a specific cantonment/family housing alternative with a specific LFTRC alternative. The driving distance between the Alternative C area and Alternatives 2, 3, and 4 is approximately 24.6 miles (39.6 km) to Alternative 2, and 30.2 miles (48.6 km) to Alternatives 3 and 4. Vehicles would use Routes 1 and 3 to commute between the Alternative C area and Alternative 2, while Routes 3, 4, 10, and 16, as well as a new roadway in Dandan, would be used to access Alternatives 3 and 4.

Five high-crash frequency intersections (intersections of Routes 1/3, Routes 1/14A, Routes 1/10A, Routes 1/14, and Routes 1/30) are situated along the travel route between the Alternative C area and Alternative 2. These intersections are primarily in the central portion of Guam in the most highly developed area of the island, within the communities of Hagåtña and Tamuning. Two high-crash frequency intersections (intersection of Routes 1/3 and Routes 8/10/16) are situated along the travel route between the Alternative C area and Alternatives 3 and 4. The travel distance between the Alternative C area and Alternatives 2, 3, and 4 is relatively long, and several high-frequency crash intersections are situated along the travel routes (resulting in a higher potential for being involved in a traffic incident or to be delayed because of traffic incidents). However, a less-than-significant additive impact on public health and safety would occur since the additional vehicles traveling between the main cantonment and LFTRC would be an insignificant portion of total vehicles on these roadways.

6.1.2.6 AAFB Cantonment/Family Housing Alternative C with NWF LFTRC Alternative 5

Air Quality

The combined air quality impacts would be the same as those described in Section 6.1.2.4. The combined construction island-wide emissions, summarized in Table 6.1.2-18, would be less than significant as a result of these combined alternatives.

Terrestrial Biological Resources

The additive impacts of implementing Cantonment/Family Housing Alternative C, LFTRC Alternative 5, and the IT/COMM infrastructure are provided in Table 6.1.2-26. Overall, approximately 1,422 acres (575 ha) of limestone forest, or 8% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 1,270 acres (514 ha) of Overlay Refuge lands, or 6% of the total Overlay Refuge currently present on Guam, would be disturbed. The proposed IT/COMM alignment contributes little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

### Cultural Resources

Adverse effects to historic properties under NHPA and impacts to other cultural resources of cultural importance resulting from the implementation of Alternatives C and 5 would be equal to the combined effects and impacts of each as discussed in Chapters 4 and 5. Additional effects and impacts could also result from the construction of the IT/COMM links for these alternatives. Construction for the IT/COMM lines for Alternative C and Alternative 5 would occur along Routes 1, 2A, 3, 3A, 4, 4A, 5, 9, 10, 15, and 17. In general, IT/COMM lines would follow existing roads; however, additional lines would be constructed at AAFB and from AAFB to Finegayan. Approximately 50% of these areas have been previously surveyed (Kurashina et al. 1987; Haun 1988; Kurashina et al. 1988; Moore et al. 1988; Amesbury and Moore 1989; Moore and Amesbury 1989; Highness and Haun 1990; Russell and Guerrero 1991; Tuggle 1993; Henry et al. 1996, 1999; Hunter-Anderson 1994; Liston 1996; Reinman and Nees 1998; Olmo et al. 2000; Hunter-Anderson et al. 2001; Allen et al. 2002; Hunter-Anderson 2002; Hunter-Anderson and Moore 2002, 2003; Dixon et al. 2004, 2011a, 2011b, 2015a, 2015b; Yee et al. 2004; DeFant and Guerrero 2006; Grant et al. 2007; Church et al. 2009; Athens 2009; Welch 2010; Dixon and Walker 2011; DeFant 2013). As not all of the routes have been surveyed, a literature review of previous surveys and sites located within the construction corridor was undertaken and the likelihood of finding buried cultural resources within PDIA for the IT/COMM lines corridor was assessed based on the level of disturbance, the proximity of known sites, and historic land use (Dixon et al. 2014). Within the PDIA for the IT/COMM lines, approximately 1% of Route 1, 57% of Route 2A, 100% of Route 3, 67% of Route...
3A, 4% of Route 4, 100% of Route 4A, 16% of Route 5, 71% of Route 9, none of Route 10, 59% of Route 15, and 1% of Route 17 have been surveyed.

Table 6.1.2-27 lists 14 known archaeological sites within the IT/COMM lines PDIA. Three of the sites, including remnants of an historic encampment, a Latte Period artifact scatter, and portions of NWF, are eligible to the NRHP. Eleven archaeological sites are not eligible for listing in the NRHP. The literature review indicated that there are also areas that were not previously surveyed that have potential for buried cultural resources along Routes 1, 5, 15, and 17.

Legend: GHPI = Guam Historic Properties Inventory; NRHP = National Register of Historic Places; NA = not applicable; NRHP criterion A = eligible because they are associated with events that have made a significant contribution to the broad pattern of history, criterion D = eligible for potential to yield information important in prehistory or history.

Notes: *Not all sites recorded within the project areas have received official GHPI numbers, although they have been documented as part of previous surveys.
**Revised to match Guam GHPI forms dated May 28, 2014.
***The Guam SHPO concurs with this recommendation (Guam SHPO correspondence dated July 2 and September 17, 2014 [RC2013-0853]).
One structure eligible for listing in the NRHP, North Field, is located within the potential impacted area. No TCPs have been identified in the potential impacted areas for the IT/COMM lines.

The installation of IT/COMM links between Alternative C and the LFTRC Alternative 5 has the potential to result in adverse effects from excavation and soil removal to four historic properties—three NRHP-eligible archaeological sites (see Table 6.1.2-27) and one NRHP-eligible structure (North Field). Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the remaining areas. No TCPs would be directly affected by the construction of the IT/COMM links.

No direct or indirect adverse effects due to operation of the IT/COMM utilities would occur as these lines would be buried and there would be no change in use, and no effects to the setting.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. To the degree possible, impacts to historic properties and other resources of cultural importance would be avoided during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, potential minimization and mitigation measures may include data recovery and monitoring during construction. However, final mitigation will be determined after completion of the consultation process outlined in the PA. With the implementation of these measures and processes as outlined in the 2011 PA, additive impacts associated with IT/COMM would be reduced to a level below significance.

**Ground Transportation**

Alternative C was modeled with Alternative 2 or 4 (Section 3.12.1). Pairing Alternative C with Alternative 5 may result in a slight increase (less than 5%) in vehicles on roadway segments and at intersections that comprise the most direct route between the Alternative C Main Gate and the Alternative 5 gate and a slight decrease in vehicles on roadway segments and at intersections that comprise the most direct route between the modeled combination, Alternative C Main Gate and the Alternative 2 or 4 gate (see Figure 6.1.2-3). This minimal incremental increase or decrease in traffic volumes would not adversely affect LOS on roadways or at intersections along the route.

Although significant impacts would occur at all locations, potential mitigation measures have not been identified for any of the impacted roadway segments or intersections. Potential mitigation measures would be similar in scope and scale to those identified in Section 6.1.2.1. However, the exact details of the improvements would require further evaluations and technical studies to determine their feasibility. The final list of implementable mitigation measures will be dependent on the selected alternative or combination of alternatives and based on project-level technical studies, to be conducted after the alternative or combination of alternatives is selected. FHWA will conduct all NEPA documentation efforts and any associated resource consultations as specific mitigation measures are proposed.

**Roadway Segment Operations.** Impacts to all off-base (external) roadway segments would be the same as those identified in Section 6.1.2.4. Significant impacts were identified on six roadway segments. The detailed results of the roadway segment analysis are provided in their entirety in Appendix F.

**Intersection Operations.** Impacts to all intersections would be the same as those identified in Section 6.1.2.4 (Table 6.1.2-21). Significant impacts were identified at 11 intersections. The detailed results of the intersection analysis are provided in its entirety in Appendix F.
Transit Conditions. Transit conditions under Alternative C with Alternative 5 would be the same as those described in Section 6.1.2.1 for Alternative A with Alternative 1.

Pedestrian and Bicycle Conditions. Pedestrian and bicycle conditions under Alternative C with Alternative 5 would be the same as those described in Section 6.1.2.1 for Alternative A with Alternative 1.

Public Health and Safety

The potential for traffic incidents is the primary health and safety issue with potential for having additive impacts from implementing a specific cantonment/family housing alternative with a specific LFTRC alternative. The driving distance between the Alternative C area and Alternative 5 is approximately 6.5 miles. Vehicles would use Routes 9 and 3A to commute between the Alternative C area and Alternative 5. No high-crash frequency intersections are situated along this travel route. Because the travel distance between the Alternative C area and Alternative 5 is relatively short and there are no high-frequency crash intersections situated along the travel route, no significant additive traffic impacts would occur.

6.1.2.7 Barrigada Cantonment/Family Housing Alternative D with Route 15 LFTRC Alternative 1

Air Quality

The combined air quality impacts would be similar to those described in Section 6.1.2.1.

The combined construction island-wide emissions impacts, summarized in Table 6.1.2-28, would be below the significance criterion of 250 tpy for criteria pollutants resulting in less than significant as a result of this combined alternative.

Terrestrial Biological Resources

The additive impacts of implementing Cantonment Housing Alternative D, LFTRC Alternative 1, and the IT/COMM infrastructure are provided in Table 6.1.2-29. Overall, approximately 518 acres (210 ha) of limestone forest, or 3% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 126 acres (51 ha) of Overlay Refuge lands, or <1% of the total Overlay Refuge currently present on Guam, would be disturbed. In regards to recovery habitat for ESA-listed species, the greatest impact would be to Guam rail recovery habitat with 1,291 acres (522 ha) developed, mostly associated with Alternative D. The proposed IT/COMM alignment contributes little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

### Cultural Resources

Adverse effects to historic properties under NHPA and impacts to other cultural resources of cultural importance resulting from the implementation of Alternatives D and 1 would be equal to the combined effects and impacts of each as discussed in Chapters 4 and 5. Additional effects and impacts could also result from the construction of the IT/COMM links for these alternatives. Construction for the IT/COMM lines for Alternative D andAlternative 1 would occur along Routes 1, 2A, 3, 3A, 4, 4A, 5, 8, 9, 10, 15, 16, and 17. In general, IT/COMM lines would follow existing roads; however, additional lines would be constructed at AAFB and from AAFB to Finegayan. Approximately 48% of these areas have been previously surveyed (Kurashina et al. 1987; Davis 1983; April 1984; Haun 1988; Kurashina et al. 1988; Amesbury and Moore 1989; Moore and Amesbury 1989; Highness and Haun 1990; Russell and Guerrero 1991; Henry et al. 1996, 1999; Hunter-Anderson 1994; Liston 1996; Reinman and Nees 1998; Olmo et al. 2000; Allen et al. 2002; Hunter-Anderson 2002; Hunter-Anderson and Moore 2002, 2003; Dixon et al. 2004, 2011a, 2011b, 2015a, 2015b; Yee et al. 2004; DeFant and Guerrero 2006; Grant et al. 2007; Church et al. 2009; Athens, 2009; Welch 2010; Dixon and Walker 2011; DeFant 2013). As not all of the routes have been surveyed, a literature review of previous surveys and sites located within the construction corridor was undertaken and the likelihood of finding buried cultural resources within PDIA for the IT/COMM lines corridor was assessed based on the level of disturbance, the proximity of known sites, and historic land use (Dixon et al. 2014). Within the PDIA for the IT/COMM lines, approximately 12% of Route 1, 57% of Route 2A, 100% of Route 3, 67% of Route 3A, 4% of Route 4, 100% of Route 4A, 16% of Route 5, none of Route 8, 70% of Route 9, 1% of Route 10, 67% of Route 15, 50% of Route 16, 1% and 2% of Route 17 have been surveyed.
Table 6.1.2-30 lists 15 known archaeological sites within the IT/COMM lines PDIA. Four of the sites, including remnants of an historic encampment, two Latte Period artifact scatters, and portions of NWF, are eligible to the NRHP. Eleven archaeological sites are not eligible for listing in the NRHP. The literature review indicated that there are also areas that were not previously surveyed that have potential for buried cultural resources along Routes 1, 5, 15, and 17.

Legend: GHPI = Guam Historic Properties Inventory; NRHP = National Register of Historic Places; NA=not applicable; NRHP criterion A = eligible because they are associated with events that have made a significant contribution to the broad pattern of history, criterion D = eligible for potential to yield information important in prehistory or history.

Notes: †Not all sites recorded within the project areas have received official GHPI numbers, although they have been documented as part of previous surveys.
***Revised to match Guam GHPI forms dated May 28, 2014.
****The Guam SHPO concurs with this recommendation (Guam SHPO correspondence dated July 2 and September 17, 2014 [RC2013-0853]).
One structure eligible for listing in the NRHP, North Field, is located within the potential impacted area. No TCPs have been identified in the potential impacted areas for the IT/COMM lines.

The installation of IT/COMM links between Alternative D and the LFTRC Alternative 1 has the potential to result in adverse effects from excavation and soil removal to five historic properties--four NRHP-eligible archaeological sites (see Table 6.1.2-30) and one NRHP-eligible structure (North Field). Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the remaining areas. No TCPs would be directly affected by the construction of the IT/COMM links.

No direct or indirect adverse effects due to operation of the IT/COMM utilities would occur as these lines would be buried and there would be no change in use, and no effects to the setting.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. To the degree possible, impacts to historic properties and other resources of cultural importance would be avoided during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, potential minimization and mitigation measures may include data recovery and monitoring during construction. However, final mitigation will be determined after completion of the consultation process outlined in the PA. With the implementation of these measures and processes as outlined in the 2011 PA, additive impacts associated with IT/COMM would be reduced to a level below significance.

Ground Transportation

The travel demand modeling methodology for the combination of alternatives was defined and directed by the DoD and the FHWA to provide detailed off-base (external) roadway and intersection analysis for one representative pairing (the modeled combination) for a cantonment/family housing alternative and LFTRC site alternative. The modeled combination for Alternative D involved a pairing with Alternative 5 (see Section 3.12.1). Modeling results for this scenario indicate that weekday a.m. peak hour vehicle traffic related to the proposed action is generated solely by operations at the cantonment/family housing area. LFTRC-related traffic would occur prior to the start weekday a.m. peak hour (8:00 a.m.) and may coincide with the weekday p.m. peak hour (4:30 p.m. to 5:30 p.m.) (see Section 5.1.12).

Operations of the LFTRC would increase traffic on the off-base (external) roadway segments and intersections that comprise the most direct route between the main cantonment gate and the LFTRC gates by approximately 38 vehicles (measured in passenger car equivalents) (see Table 5.1.12-2). LFTRC-related traffic represents an insubstantial amount of traffic (less than 5%) along the route. This minimal incremental increase in traffic volumes would not adversely affect LOS on roadways or at intersections along the route. The relative contribution from LFTRC traffic to the off-base (external) roadway segments and intersections under each cantonment/family housing alternative would be minimal and would not vary appreciably with any LFTRC alternative (Alternative 1, 2, 3, 4, and 5). Therefore, the impacts to the off-base (external) roadway segments and intersections would be essentially the same for Alternative D with Alternative 1, Alternative D with Alternative 2, 3, or 4, and Alternative D with Alternative 5. A qualitative discussion of the potential effects of LFTRC-related traffic is provided for each combination.
Pairing Alternative D with Alternative 1 may result in a slight increase in vehicles (less than 5%) on roadway segments and at intersections that comprise the most direct route between the Alternative D Main Gate and the Alternative 1 gate, and a slight decrease in vehicles compared to the modeled combination of Alternative D Main Gate and the Alternative 5 gate (Figure 6.1.2-4). This minimal incremental increase or decrease in traffic volumes would not adversely affect LOS on roadways or at intersections along the route. The impacts to off-base (external) roadway segments and intersections are summarized in Table 6.1.2-31.

Legend: NA indicates Not Applicable. SI indicates significant impact.

Notes: *Includes impacts to roadway segments in at least one direction during one (or both) weekday a.m. or p.m. peak hours.
**Indicates a significant but mitigable impact has been identified at this location under Year 2030 Alternative A.

Roadway Segment Operations. A capacity analysis was conducted to determine potential impacts to the off-base (external) roadway network during weekday a.m. and p.m. peak hours. The volume-to-capacity ratio and LOS for each study roadway segment is compared to the baseline conditions to determine if any significant impacts would occur. The detailed results of the roadway segment analysis are provided in their entirety in Appendix F.

The addition of traffic generated by the proposed action would result in a potentially significant impact on 12 study roadway segments in at least one direction during the weekday a.m. and/or weekday p.m. peak hours.

- **Route 15, from Route 26 to Route 29.** This study roadway segment currently operates at acceptable LOS E with a v/c ratio of 0.96 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.08 in the southbound/westbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study roadway segment would continue to operate at LOS F with a v/c ratio of 1.17. The proposed action would increase traffic on this study roadway segment by approximately 63 vehicles during the weekday a.m. peak hour. This 7.5% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact in the southbound/westbound direction on this study roadway segment during the weekday p.m. peak hour.
Figure 6.1.2-4
Travel Routes from Barrigada Cantonment/Housing (Alternative D) to the LFTRC Alternatives

Source: NAVFAC Pacific 2013

Legend
Travel Routes from Barrigada Cantonment/Housing (Alternative D) to the LFTRC Alternatives
- Northwest Field (16.9 mi/27.2 km)
- Route 15 (5.8 mi/9.3 km)
- NAVMAG East-West (17 mi/27.4 km)
- NAVMAG L-Shaped (17 mi/27.4 km)
- NAVMAG North-South (17.7 mi/28.5 km)
- Highways
- Airfields
- Barrigada Cantonment/Housing Alternative (Alt. D)
- LFTRC Alternatives
- DoD Properties
- **Route 1, from Route 30 to Route 8.** This study roadway segment currently operates at acceptable LOS E with a v/c ratio of 0.91 in the northbound/eastbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would operate at acceptable LOS E with a v/c ratio of 0.98 in the northbound/eastbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study roadway segment would degrade to unacceptable LOS F with a v/c ratio of 1.01. Therefore, the proposed action would result in a significant impact in the northbound/eastbound direction on this study roadway segment during the weekday a.m. peak hour.

- **Route 1, from Route 6 (N) to Route 11.** This study roadway segment currently operates at LOS E with a v/c ratio of 0.99 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.05 in the southbound/westbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.11 in the southbound/westbound direction. The proposed action would increase traffic on this study roadway segment by approximately 95 vehicles during the weekday a.m. peak hour. This 5.4% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact on this study roadway segment in the southbound/westbound direction during the weekday a.m. peak hour.

- **Route 8, from Route 10 to Route 33 (E).** This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.13 in the southbound/westbound direction under Existing Conditions. Traffic volumes would decrease and this study roadway segment would improve to operate at acceptable LOS E with a v/c ratio of 0.95 in the southbound/westbound during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study roadway segment would degrade to operate at LOS F with a v/c ratio of 1.07. Therefore, the proposed action would result in a significant impact on this study roadway segment in the southbound/westbound directions during the weekday a.m. peak hour.

- **Route 8, from Route 33 (E) to Route 33 (W).** This study roadway segment currently operates at acceptable LOS D with a v/c ratio of 0.89 and unacceptable LOS F with a v/c ratio of 1.14 in the northbound/eastbound direction during the weekday a.m. and p.m. peak hours, respectively. This study roadway segment would operate at acceptable LOS E with a v/c ratio of 0.98 and would continue to operate at unacceptable LOS F with a v/c ratio of 1.29 in the northbound/eastbound direction during the weekday a.m. and p.m. peak hours, respectively under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study roadway segment would degrade to operate at unacceptable LOS F with a v/c ratio of 1.03 and would continue to operate at unacceptable LOS F with a v/c ratio of 1.38 in the northbound/eastbound direction during the weekday a.m. and p.m. peak hours, respectively. The proposed action would increase traffic on this study roadway segment by approximately 148 vehicles during the weekday p.m. peak hour. This 6.7% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact in the northbound/eastbound direction on this study roadway segment during the weekday a.m. and p.m. peak hours. This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.13 and acceptable LOS C with a v/c ratio of 0.78 in the southbound/westbound...
direction during the weekday a.m. and p.m. peak hours, respectively under Existing Conditions. This study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.16 and 1.03 in the southbound/westbound direction during the weekday a.m. and p.m. peak hours, respectively under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) this roadway segment would continue to operate at LOS F with a v/c ratio of 1.26 and 1.10 during the weekday a.m. and p.m. peak hours, respectively. The proposed action would increase traffic on this study roadway segment by approximately 162 and 114 vehicles during the weekday a.m. and p.m. peak hours, respectively. This 8.0% and 6.5% increase in traffic exceeds the 5.0% threshold of significance during the weekday a.m. and p.m. peak hours. Therefore, the proposed action would result in a significant impact on this study roadway segment in the northbound/eastbound and southbound/westbound directions during the weekday a.m. peak hour and p.m. peak hours.

- **Route 8**, from Route 1 to Route 33 (W). This study roadway segment currently operates at acceptable LOS D with a v/c ratio of 0.81 in the northbound/eastbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would operate at acceptable LOS E with a v/c ratio of 0.98 in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study roadway segment would degrade to operate at unacceptable LOS F with a v/c ratio of 1.05. Therefore, the proposed action would result in a significant impact in the northbound/eastbound direction on this study roadway segment during the weekday p.m. peak hour.

- **Route 10**, from Route 8 to Route 15. This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.14 in the northbound/eastbound direction during the weekday a.m. peak hour and operates at acceptable LOS D with a v/c ratio of 0.89 in the southbound/westbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.26 in the northbound/eastbound direction during the weekday a.m. peak hour and a v/c ratio of 1.00 in the southbound/westbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.36 in the northbound/eastbound direction during the weekday a.m. peak hour and a v/c ratio of 1.13 in the southbound/westbound direction during the weekday p.m. peak hour. The proposed action would increase traffic on this study roadway segment by approximately 156 vehicles in the northbound/eastbound direction during the weekday a.m. peak hour and by 207 vehicles in the southbound/westbound direction during the weekday p.m. peak hour. This 7.2% increase in traffic in the northbound/eastbound during the weekday a.m. peak hour and 11.5% increase in traffic in the southbound/westbound directions during the weekday p.m. peak hour exceed the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact on this study roadway segment in the northbound/eastbound direction during the weekday a.m. peak hour and in the southbound/westbound direction during the weekday p.m. peak hour.

- **Route 10**, from Route 15 to Route 32. This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.05 in the northbound/eastbound direction during the weekday a.m. peak hour and operates at acceptable LOS D with a v/c ratio of 0.85 in the southbound/westbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.17 in the northbound/eastbound direction during the weekday a.m. peak hour and at acceptable LOS E with
a v/c ratio of 0.96 in the southbound/westbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.23 in the northbound/eastbound direction during the weekday a.m. peak hour and would degrade to operate at unacceptable LOS F with a v/c ratio of 1.01 in the southbound/westbound direction during the weekday p.m. peak hour. The proposed action would increase traffic on this study roadway segment by approximately 97 vehicles in the northbound/eastbound direction during the weekday a.m. peak hour. This 5.1% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact on this study roadway segment in the northbound/eastbound direction during the weekday a.m. peak hour and in the southbound/westbound direction during the weekday p.m. peak hour.

- **Route 15, from Route 26 to Barrigada South Gate.** This study roadway segment currently operates at acceptable LOS D with a v/c ratio of 0.90 in the northbound/eastbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.06 in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.24 in the northbound/eastbound direction during the weekday a.m. peak hour. The proposed action would increase traffic on this study roadway segment by approximately 131 vehicles in the northbound/eastbound direction during the weekday a.m. peak hour. This 14.7% increase in traffic exceeds the 5.0% threshold of significance. This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.05 and acceptable LOS C with a v/c ratio of 0.76 in the southbound/westbound direction during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions. This study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.28 and would degrade to operate at unacceptable LOS F during the weekday a.m. and p.m. peak hours, respectively, in the southbound/westbound direction. The proposed action would increase traffic on this study roadway segment by approximately 125 vehicles in the southbound/westbound direction during the weekday a.m. peak hour. This 13.5% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact on this study roadway segment in the northbound/eastbound direction during the weekday p.m. peak hour and in the southbound/westbound direction during the weekday a.m. and p.m. peak hours.

- **Route 15, from Barrigada South Gate to Route 10.** This study roadway segment currently operates at acceptable LOS A with a v/c ratio of 0.46 and acceptable LOS D with a v/c ratio of 0.90 in the northbound/eastbound direction during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions. This study roadway segment would continue to operate at acceptable LOS A with a v/c ratio of 0.60 and would operate at unacceptable LOS F with a v/c ratio of 1.02 in the northbound/eastbound direction during the weekday a.m. and p.m. peak hours, respectively, under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study roadway segment would...
degrade to operate at LOS F with a v/c ratio of 1.06 during the weekday a.m. peak hour and would continue to operate at unacceptable LOS F with a v/c ratio of 1.38 during the weekday p.m. peak hour in the northbound/eastbound direction. The proposed action would increase traffic on this study roadway segment by approximately 274 vehicles in the northbound/eastbound direction during the weekday p.m. peak hour. This 26.2% increase in traffic exceeds the 5.0% threshold of significance. This study roadway segment currently operates at acceptable LOS E with a v/c ratio of 0.93 and LOS B with a v/c ratio of 0.62 in the southbound/westbound direction during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.00 and at acceptable LOS C with a v/c ratio of 0.74 in the southbound/westbound direction during the weekday a.m. and p.m. peak hours, respectively, under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.25 and would degrade to operate at unacceptable LOS F with a v/c ratio of 1.22 during the weekday a.m. and p.m. peak hours, respectively, in the southbound/westbound direction. The proposed action would increase traffic on this study roadway segment by approximately 361 vehicles in the southbound/westbound direction during the weekday p.m. peak hour. This 39.2% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact on this study roadway segment in both directions during the weekday a.m. and p.m. peak hours.

- **Route 16, from Route 10A to Barrigada Main Gate.** This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.03 and 1.09 in the northbound/eastbound direction during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions. This study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.07 and 1.05 in the northbound/eastbound direction during the weekday a.m. and p.m. peak hours, respectively, under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study roadway segment would continue to operate at LOS F with a v/c ratio of 1.16 and 1.10 during the weekday a.m. and p.m. peak hours. The proposed action would increase traffic on this study roadway segment by approximately 138 and 90 vehicles in the northbound/eastbound direction during the weekday a.m. and p.m. peak hours, respectively. This 7.4% and 5.1% increase in traffic exceeds the 5.0% threshold of significance. This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.01 and 1.09 in the southbound/westbound direction during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.13 in the southbound/westbound direction during the weekday p.m. peak hour, under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.24 during the weekday a.m. peak hour, in the southbound/westbound direction. The proposed action would increase traffic on this study roadway segment by approximately 165 vehicles in the southbound/westbound direction during the weekday p.m. peak hour. This 8.3% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact on this study roadway segment in the northbound/eastbound direction during the weekday a.m. and p.m. peak hours and in the southbound/westbound direction during the weekday p.m. peak hour.

- **Route 26, from Route 25 to Route 15.** This study roadway segment currently operates at acceptable LOS D with a v/c ratio of 0.84 in the northbound/eastbound direction during the
weekday p.m. peak hour, under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.01 in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.08. The proposed action would increase traffic on this study roadway segment by approximately 47 vehicles in the northbound/eastbound direction during the weekday a.m. peak hour. This 6.1% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact on this study roadway segment in the northbound/eastbound direction during the weekday a.m. peak hour.

Although significant impacts would occur at all locations, potential mitigation measures have not been identified for any of the impacted roadway segments. Potential mitigation measures would be similar in scope and scale to those identified in Section 6.1.2.1. However, the exact details of the improvements would require further evaluations and technical studies to determine their feasibility. The final list of implementable mitigation measures will be dependent on the selected alternative or combination of alternatives and based on project-level technical studies, to be conducted after the alternative or combination of alternatives is selected. FHWA will conduct all NEPA documentation efforts and any associated resource consultations as specific mitigation measures are proposed.

**Intersection Operations.** Intersection analysis was conducted to determine potential impacts to the off-base (external) intersections during weekday a.m. and p.m. peak hours. The LOS for each study intersection is compared to the baseline conditions to determine if any significant impacts would occur. An impact summary is provided in Table 6.1.2-31. The detailed results of the intersection analysis are provided in their entirety in Appendix F.

The addition of traffic generated by the proposed action would potentially result in a significant impact at eight study intersections during the weekday a.m. and/or weekday p.m. peak hours.

- **Route 15 / Chalan Lajuna.** This two-way stop-controlled study intersection currently operates at acceptable LOS D with 30.7 seconds of delay and acceptable LOS C with 23.9 seconds of delay during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions. This study intersection would operate at unacceptable LOS F with 75.8 and 82.6 seconds of delay during the weekday a.m. and p.m. peak hours, respectively, under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday a.m. and p.m. peak hours. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. and p.m. peak hours.

- **Route 1 / Route 27.** This signalized study intersection currently operates at acceptable LOS E with 70.3 seconds of delay during the weekday a.m. peak hour under Existing Conditions. This study intersection would operate at unacceptable LOS F with 118.3 seconds of delay during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study intersection would continue to operate at unacceptable LOS F with 134.1 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour.
• **Route 1 / Route 26.** This signalized study intersection currently operates at acceptable LOS C with 27.9 seconds of delay during the weekday p.m. peak hour under Existing Conditions. This intersection would operate at unacceptable LOS F with 87.6 seconds of delay during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study intersection would continue to operate at unacceptable LOS F with 94.9 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday p.m. peak hour.

• **Route 16 / Route 27.** This signalized study intersection currently operates at acceptable LOS C with 50.1 seconds of delay and acceptable LOS E with 71.2 seconds of delay during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions. This intersection would operate at unacceptable LOS F with greater than 180.0 seconds of delay and 154.7 seconds of delay during the weekday a.m. and p.m. peak hours, respectively under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay and unacceptable LOS F with 165.9 seconds of delay during the weekday a.m. and p.m. peak hours, respectively. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. and p.m. peak hours.

• **Route 15 / Route 26.** This two-way stop-controlled study intersection currently operates at unacceptable LOS F with 32.1 seconds of delay and 147.3 seconds of delay during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions. This study intersection would operate at unacceptable LOS F with 145.2 seconds of delay and greater than 180.0 seconds of delay during the weekday a.m. and p.m. peak hours, respectively under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday a.m. and p.m. peak hours. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. and p.m. peak hours.

• **Route 1 / Route 10A.** This signalized study intersection currently operates at acceptable LOS E with 62.6 seconds of delay during the weekday p.m. peak hour under Existing Conditions. This study intersection would operate at unacceptable LOS F with 139.3 seconds of delay during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study intersection would continue to operate at unacceptable LOS F with 143.2 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday p.m. peak hour.

• **Route 8 / Chalan Santo Papa.** This two-way stop-controlled study intersection currently operates at unacceptable LOS F with 55.1 seconds of delay and 53.0 seconds of delay during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions. This study intersection would continue to operate at unacceptable LOS F with 86.5 seconds of delay and 158.9 seconds of delay during the weekday a.m. and p.m. peak hours, respectively under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study intersection would continue to operate at unacceptable LOS F with 127.7 seconds of delay and greater than 180.0 seconds of delay during the weekday a.m. and p.m. peak hours, respectively.
The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. and p.m. peak hours.

- **Route 4 / Route 7B.** This signalized study intersection currently operates at acceptable LOS E with 45.7 seconds of delay during the weekday p.m. peak hour under Existing Conditions. This study intersection would operate at unacceptable LOS F with 161.3 seconds of delay during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Barrigada Cantonment/Family Housing (Alternative D) Conditions, this study intersection would continue to operate at unacceptable LOS F with 171.6 seconds of delay during the weekday p.m. peak hour. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday p.m. peak hour.

Although significant impacts would occur at all locations, potential mitigation measures have not been identified for any of the impacted roadway segments or intersections. Potential mitigation measures would be similar in scope and scale to those identified in Section 6.1.2.1. However, the exact details of the improvements would require further evaluations and technical studies to determine their feasibility. Potential. The final list of implementable mitigation measures will be dependent on the selected alternative or combination of alternatives and based on project-level technical studies, to be conducted after the alternative or combination of alternatives is selected. FHWA will conduct all NEPA documentation efforts and any associated resource consultations as specific mitigation measures are proposed.

**Transit Conditions.** There would be no impacts to transit conditions under Alternative D with Alternative 1.

**Pedestrian and Bicycle Conditions.** There would be no impacts to pedestrian and bicycle conditions under Alternative D with Alternative 1.

**Public Health and Safety**

The potential for traffic incidents is the primary health and safety issue with potential for having additive impacts from implementing a specific cantonment/family housing alternative with a specific LFTRC alternative. The driving distance between the proposed Barrigada Cantonment/Family Housing (Alternative D) area and Alternative 1 is approximately 5.8 miles. Vehicles would use Routes 8, 10 and 15 to commute between the Alternative D area and Alternative 1.

One high-crash frequency intersection (intersection of Routes 8/10/16) is situated along the travel route between the Alternative D area and Alternative 1. This intersection is in the central portion of Guam and must be driven through when arriving/leaving the Barrigada Main Gate because Route 8 provides direct access to the Alternative D area. The travel distance between the Alternative D area and Alternative 1 is relatively short however, with this one high-frequency crash intersection situated along the travel route resulting in a higher potential for being involved in a traffic incident or to be delayed because of traffic incidents. Because the travel distance is short, a less-than-significant additive impact on traffic would occur.
6.1.2.8 Barrigada Cantonment/Family Housing Alternative D with any NAVMAG LFTRC Alternative (Alternatives 2, 3, or 4)

**Air Quality**

The combined air quality impacts would be similar to those described in Section 6.1.2.1. The combined construction island-wide emissions, summarized in Section 6.1.2.7 and Table 6.1.2-28, would be less than significant as a result of these combined alternatives.

**Terrestrial Biological Resources**

*Barrigada Cantonment/Family Housing Alternative D with NAVMAG (East/West) LFTRC Alternative 2*

The additive impacts of implementing Cantonment/Family Housing Alternative D, LFTRC Alternative 2, and the IT/COMM infrastructure are provided in Table 6.1.2-32. Overall, approximately 282 acres (114 ha) of limestone forest, or 1% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 126 acres (51 ha) of Overlay Refuge lands, or <1% of the total Overlay Refuge currently present on Guam, would be disturbed. In regards to recovery habitat for ESA-listed species, the greatest impact would be to Guam rail recovery habitat with 1,057 acres (428 ha) developed, mostly associated with Alternative D. The proposed IT/COMM alignment contributes little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

**Table 6.1.2-32. Summary of Impacts to Terrestrial Biological Resources with Implementation of Barrigada Cantonment/Family Housing (Alternative D), NAVMAG (East/West) LFTRC (Alternative 2), and IT/COMM Infrastructure**

*Legend:* GMK = Guam Micronesian kingfisher, GR = Guam rail, MC = Mariana crow, MFB = Mariana fruit bat, Ser = Serianthes.

*Notes:* (1) Direct impact - conversion to developed areas.
(2) Only species for which there would be a significant impact.
Barrigada Cantonment/Family Housing Alternative D with NAVMAG (North/South) LFTRC Alternative 3

The additive impacts of implementing Cantonment/Family Housing Alternative D, LFTRC Alternative 3, and the IT/COMM infrastructure are provided in Table 6.1.2-33. Overall, approximately 432 acres (175 ha) of limestone forest, or 2% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 401 acres (162 ha) of Overlay Refuge lands, or 2% of the total Overlay Refuge currently present on Guam, would be disturbed. In regards to recovery habitat for ESA-listed species, the greatest impact would be to Guam rail recovery habitat with 1,032 acres (418 ha) developed, mostly associated with Alternative D. The proposed IT/COMM alignment contributes little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Barrigada Cantonment/Family Housing Alternative D with NAVMAG (L-Shaped) LFTRC Alternative 4

The additive impacts of implementing Cantonment/Family Housing Alternative D, LFTRC Alternative 4, and the IT/COMM infrastructure are provided in Table 6.1.2-34. Overall, 393 acres (159 ha) of limestone forest, or 2% of the total limestone forest currently present on Guam, would be disturbed. In addition, 345 acres (140 ha) of Overlay Refuge lands, or 1% of the total Overlay Refuge currently present on Guam, would be disturbed. In regards to recovery habitat for ESA-listed species, the greatest impact would be to Guam rail recovery habitat with 1,058 acres (428 ha) developed, mostly associated with Alternative D. The proposed IT/COMM alignment contributes little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Cultural Resources

Adverse effects to historic properties under NHPA and impacts to other cultural resources of cultural importance resulting from the implementation of Alternative D and Alternatives 2, 3, or 4 would be equal to the combined effects and impacts of each as discussed in Chapters 4 and 5. Additional effects and impacts could also result from the construction of the IT/COMM links for these alternatives. Construction for the IT/COMM lines for Alternative D and Alternatives 2, 3, or 4 would occur along Routes 1, 2A, 3, 3A, 4, 4A, 5, 8, 9, 10, 15, 16, and 17. In general, IT/COMM lines would follow existing roads; however, additional lines would be constructed at AAFB and from AAFB to Finegayan. Approximately 52% of these areas have been previously surveyed (Thomas and Price 1979; Davis 1983; April 1984; Kurashina et al. 1987; Amesbury and Moore 1989; Moore and Amesbury 1989; Highness and Haun 1990; Amesbury et al. 1991; Carrell 1991, Russell and Guerrero 1991; Prasad and Moore 1992; Russell et al. 1993; Henry et al. 1994, 1996, 1999; Hunter-Anderson 1994; Reinman 1995; Wells et al. 1995; Workman and Haun 1995; Liston 1996; Hunter-Anderson et al. 1995, 1997; Reinman and Nees 1998; Hunter-Anderson et al. 2001; Allen et al. 2002; Olmo et al. 2002; Hunter-Anderson 2002, 2004; Hunter-Anderson and Moore 2002, 2003; Dixon et al. 1999, 2004, 2011a, 2011b, 2015a, 2015b; Yee et al. 2004; DeFant and Guerrero 2006; Grant et al. 2007; Church et al. 2009; Athens, 2009; Welch 2010; Dixon and Walker 2011; DeFant 2013). As not all of the routes have been surveyed, a literature review of previous surveys and sites located within the construction corridor was undertaken and the likelihood of finding buried cultural resources within PDIA for the IT/COMM lines corridor was assessed based on the level of disturbance, the proximity of known sites, and historic land use (Dixon et al. 2014). Within the PDIA for
the IT/COMM lines, approximately 55% of Route 1, 61% of Route 2A, 100% of Route 3, 67% of Route 3A, 11% of Route 4, 100% of Route 4A, 16% of Route 5, 2% of Route 8, 70% of Route 9, 1% of Route 10, 72% of Route 15, 50% of Route 16, and 2% of Route 17 have been surveyed.

Table 6.1.2-35 lists 15 known archaeological sites within the IT/COMM lines PDIA for Alternatives 2, 3, and 4. Four of the sites, including remnants of an historic encampment, two Late Period artifact scatters, and portions of NWF, are eligible for listing in the NRHP. Eleven archaeological sites are not eligible for listing in the NRHP. The literature review indicated that there are also areas that were not previously surveyed that have potential for buried cultural resources along Routes 1, 5, 15, and 17.

**Legend:** GHPI = Guam Historic Properties Inventory; NRHP = National Register of Historic Places; NA = not applicable; NRHP criterion A = eligible because they are associated with events that have made a significant contribution to the broad pattern of history, criterion D = eligible for potential to yield information important in prehistory or history.

**Notes:** †Not all sites recorded within the project areas have received official GHPI numbers, although they have been documented as part of previous surveys.
**Revised to match Guam GHPI forms dated May 28, 2014.
***The Guam SHPO concurs with this recommendation (Guam SHPO correspondence dated July 2 and September 17, 2014 [RC2013-0853]).
One structure eligible for listing in the NRHP, North Field, is located within the potential impacted area for Alternatives 2, 3, and 4. No TCPs have been identified in the potential impacted areas for the IT/COMM lines.

The installation of IT/COMM links between Alternative D and the LFTRC Alternatives 2, 3, or 4 has the potential to result in adverse effects from excavation and soil removal to five historic properties, including four NRHP-eligible archaeological sites (see Table 6.1.2-35) and one NRHP-eligible structure (North Field). Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the remaining areas. No TCPs would be directly affected by the construction of the IT/COMM links.

No direct or indirect adverse effects due to operation of the IT/COMM utilities would occur as these lines would be buried and there would be no change in use, and no effects to the setting.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. To the degree possible, impacts to historic properties and other resources of cultural importance would be avoided during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, potential minimization and mitigation measures may include data recovery and monitoring during construction. However, final mitigation will be determined after completion of the consultation process outlined in the PA. With the implementation of these measures and processes as outlined in the 2011 PA, additive impacts associated with IT/COMM would be reduced to a level below significance.

Ground Transportation

Alternative D was modeled with Alternative 5 (Section 3.12.1). Pairing Alternative D with Alternative 2, 3, or 4 may result in a slight increase (less than 5%) in vehicles on roadway segments and at intersections that comprise the most direct route between the Alternative D Main Gate and the Alternative 2, 3, or 4 gates, as well as a slight decrease in vehicles on roadway segments and at intersections that comprise the most direct route between the modeled combination Alternative D Main Gate and the Alternative 5 gate (see Figure 6.1.2-4). This minimal incremental increase or decrease in traffic volumes would not adversely affect LOS on roadways or at intersections along the route.

Although significant impacts would occur at all locations, potential mitigation measures have not been identified for any of the impacted roadway segments or intersections. Potential mitigation measures would be similar in scope and scale to those identified in Section 6.1.2.1. However, the exact details of the improvements would require further evaluations and technical studies to determine their feasibility. The final list of implementable mitigation measures will be dependent on the selected alternative, or combination of alternatives and based on project-level technical studies to be conducted after the alternative or combination of alternatives is selected. FHWA will conduct all NEPA documentation efforts and any associated resource consultations as specific mitigation measures are proposed.

**Roadway Segment Operations.** Impacts to all off-base (external) roadway segments would be the same as those identified in Section 6.1.2.7. Significant impacts were identified on 12 roadway segments. The detailed results of the roadway segment analysis are provided in their entirety in Appendix F.

**Intersection Operations.** Impacts to all intersections would be the same as those identified in Section 6.1.2.7 (see Table 6.1.2-31). Significant impacts were identified at eight intersections. The detailed results of the intersection analysis are provided in its entirety in Appendix F.
Transit Conditions. Transit conditions under Alternative D with Alternative 2, 3, or 4 would be similar to those described in Section 6.1.2.7 for Alternative D with Alternative 1.

Pedestrian and Bicycle Conditions. Pedestrian and bicycle conditions under Alternative D with Alternative 2, 3, or 4 would be similar to those described in Section 6.1.2.7 for Alternative D with Alternative 1.

Public Health and Safety

The potential for traffic incidents is the primary health and safety issue with potential for having additive impacts from implementing a specific cantonment/family housing alternative with a specific LFTRC alternative. The driving distance between the Alternative D area and Alternatives 2, 3, and 4 is approximately 18 miles (29 km) to Alternative 2, and approximately 17 miles (27 km) to Alternatives 3 and 4. Vehicles would use Routes 1, 8, and 10 to commute between the Alternative D area and Alternative 2, while Routes 4, 8, and 10, as well as a new roadway in Dandan, would be used to access Alternatives 3 and 4.

One high-crash frequency intersection (intersection of Routes 8/10/16) is situated along the travel route between the Alternative D area and Alternatives 2, 3, and 4. This intersection is in the central portion of Guam, and because Route 8 provides direct access to the Alternative D area, this intersection must be driven through when arriving/leaving the Barrigada Main Gate. The travel distance between the Alternative D area and Alternatives 2, 3, and 4 is relatively long, with one high-frequency crash intersection situated along the travel route, resulting in a higher potential for being involved in a traffic incident or to be delayed because of traffic incidents. However, a less than significant additive impact on traffic would occur.

6.1.2.9 Barrigada Cantonment/Family Housing Alternative D with NWF LFTRC Alternative 5

Air Quality

The combined air quality impacts would be similar to those described in Section 6.1.2.1.

The combined construction island-wide emissions, summarized in Section 6.1.2.7 and Table 6.1.2-28, would be less than significant as a result of these combined alternatives.

Terrestrial Biological Resources

The additive impacts of implementing Cantonment/Family Housing Alternative D, LFTRC Alternative 5, and the IT/COMM infrastructure are provided in Table 6.1.2-36. Overall, 482 acres (195 ha) of limestone forest, or 2% of the total limestone forest currently present on Guam, would be disturbed. In addition, 424 acres (172 ha) of Overlay Refuge lands, or 2% of the total Overlay Refuge currently present on Guam, would be disturbed. In regards to recovery habitat for ESA-listed species, the greatest impact would be to Guam rail recovery habitat with 1,090 acres (441 ha) developed, mostly associated with Alternative D. The proposed IT/COMM alignment contributes little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Cultural Resources

Adverse effects to historic properties under NHPA and impacts to other cultural resources of cultural importance resulting from the implementation of Alternatives D and 5 would be equal to the combined effects and impacts of each as discussed in Chapters 4 and 5. Additional effects and impacts could also result from the construction of the IT/COMM links for these alternatives. Construction for the IT/COMM lines for Alternative D and Alternative 5 would occur along Routes 1, 2A, 3, 3A, 4, 4A, 5, 8, 9, 10, 15, 16, and 17. In general, IT/COMM lines would follow existing roads; however, additional lines would be constructed at AAFB and from AAFB to Finegayan. Approximately 49% of these areas have been previously surveyed (Davis 1983; April 1984; Kurashina et al. 1988; Amesbury and Moore 1989; Moore and Amesbury 1989; Highness and Haun 1990; Russell and Guerrero 1991; Henry et al. 1996, 1999; Hunter-Anderson 1994; Liston 1996; Reinman and Nees 1998; Olmo et al. 2000; Allen et al. 2002; Hunter-Anderson 2002; Hunter-Anderson and Moore 2002, 2003; Dixon et al. 2004, 2011a, 2011b, 2015a, 2015b; Yee et al. 2004; DeFant and Guerrero 2006; Grant et al. 2007; Church et al. 2009; Athens, 2009; Welch 2010; Dixon and Walker 2011; DeFant 2013). As not all of the routes have been surveyed, a literature review of previous surveys and sites located within the construction corridor was undertaken and the likelihood of finding buried cultural resources within PDIA for the IT/COMM lines corridor was assessed based on the level of disturbance, the proximity of known sites, and historic land use (Dixon et al. 2014). Within the PDIA for the IT/COMM lines, approximately 12% of Route 1, 57% of Route 2A, 100% of Route 3, 100% of Route 3A, 4% of Route 4, 100% of Route 4A, 16% of Route 5, none of Route
8, 70% of Route 9, 1% of Route 10, 72% of Route 15, 50% of Route 16, and 2% of Route 17 have been surveyed.

Table 6.1.2-37 lists 13 known archaeological sites within the IT/COMM lines PDIA. Four of the sites, including two Latte Period artifact scatters, an historic encampment, and portions of NWF, are eligible to the NRHP. Nine archaeological sites are not eligible for listing in the NRHP. The literature review indicated that there are also areas that were not previously surveyed that have potential for buried cultural resources along Routes 1, 5, 15, and 17.

Legend: GHPI = Guam Historic Properties Inventory; NRHP = National Register of Historic Places; NA=not applicable; NRHP criterion A = eligible because they are associated with events that have made a significant contribution to the broad pattern of history.

Notes: †Not all sites recorded within the project areas have received official GHPI numbers, although they have been documented as part of previous surveys.
**Revised to match Guam GHPI forms dated May 28, 2014.
***The Guam SHPO concurs with this recommendation (Guam SHPO correspondence dated July 2 and September 17, 2014 [RC2013-0853]).
One structure eligible for listing in the NRHP, North Field, is located within the potential impacted area. No TCPs have been identified in the potential impacted areas for the IT/COMM lines.

The installation of IT/COMM links between Alternative D and the LFTRC Alternative 5 has the potential to result in adverse effects from excavation and soil removal to five historic properties—four NRHP-eligible archaeological sites (see Table 6.1.2-37), and one NRHP-eligible structure (North Field). Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the remaining areas. No TCPs would be directly affected by the construction of the IT/COMM links.

No direct or indirect adverse effects due to operation of the IT/COMM utilities would occur as these lines would be buried and there would be no change in use, and no effects to the setting.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. To the degree possible, impacts to historic properties and other resources of cultural importance would be avoided during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, potential minimization and mitigation measures may include data recovery and monitoring during construction. However, final mitigation will be determined after completion of the consultation process outlined in the PA. With the implementation of these measures and processes as outlined in the 2011 PA, additive impacts associated with IT/COMM would be reduced to a level below significance.

**Ground Transportation**

Alternative D was modeled with Alternative 5 (Section 3.12.1). Although significant impacts would occur at all locations, potential mitigation measures have not been identified for any of the impacted roadway segments or intersections. Potential mitigation measures would be similar in scope and scale to those identified in Section 6.1.2.1. However, the exact details of the improvements would require further evaluations and technical studies to determine their feasibility. The final list of implementable mitigation measures will be dependent on the selected alternative or combination of alternatives and based on project-level technical studies, to be conducted after the alternative or combination of alternatives is selected. FHWA will conduct all NEPA documentation efforts and any associated resource consultations as specific mitigation measures are proposed.

**Roadway Segment Operations.** Impacts to all off-base (external) roadway segments would be the same as those identified in Section 6.1.2.7. Significant impacts were identified on 12 roadway segments. The detailed results of the roadway segment analysis are provided in their entirety in Appendix F.

**Intersection Operations.** Impacts to all intersections would be the same as those identified in Section 6.1.2.7 (Table 6.1.2-31). Significant impacts were identified at eight intersections. The detailed results of the intersection analysis are provided in its entirety in Appendix F.

**Transit Conditions.** Transit conditions under Alternative D with Alternative 5 would be similar to those described in Section 6.1.2.7 for Alternative D with Alternative 1.

**Pedestrian and Bicycle Conditions.** Pedestrian and bicycle conditions under Alternative D with Alternative 5 would be similar to those described in Section 6.1.2.7 for Alternative D with Alternative 1.
Public Health and Safety

The potential for traffic incidents is the primary health and safety issue with potential for having additive impacts from implementing a specific cantonment/family housing alternative with a specific LFTRC alternative. The driving distance between the Alternative D area and Alternative 5 is approximately 16.9 miles. Vehicles would use Routes 1, 3, 3A, 8, and 16 to commute between the Alternative D area and Alternative 5.

Two high-crash frequency intersections (intersection of Routes 8/10/16 and Routes 1/3) are situated along the travel route between the Alternative D area and Alternative 5. In an effort to improve vehicle safety at the intersection of Routes 8/10/16, traffic improvements were completed in 2012 that includes the installation of a new traffic signal system that reduced congestion and channelized traffic. These intersections are in the central portion of Guam and because Route 8 provides direct access to the Alternative D area, that intersection must be driven through when arriving/leaving the Barrigada Main Gate. The travel distance between the Alternative D area and Alternative 5 is relatively long, with the two high-frequency crash intersections situated along the travel route resulting in a higher potential for being involved in a traffic incident or to be delayed because of traffic incidents. However, a less-than-significant additive impact on traffic would occur.

6.1.2.10 Finegayan Cantonment/AAFB Family Housing (Alternative E) with Route 15 LFTRC (Alternative 1)

Air Quality

The combined air quality impacts would be the same as those described in Section 6.1.2.1. The combined construction island-wide emissions impacts, summarized in Table 6.1.2-1, would be less than significant as a result of this combined alternative.

Terrestrial Biological Resources

The additive impacts of implementing cantonment/family housing Alternative E with LFTRC Alternative 1 and the IT/COMM infrastructure are provided in Table 6.1.2-38. Overall, approximately 1,063 acres (430 ha) of limestone forest, or 6% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 1,148 acres (465 ha) of Overlay Refuge lands, or 5% of the total Overlay Refuge currently present on Guam, would be disturbed. The majority (73%) of the impacts to terrestrial biological resources would occur under Alternative E, with 780 acres (316 ha) of limestone forest disturbed. The proposed IT/COMM alignment contributes very little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.
Table 6.1.2-38. Summary of Impacts to Terrestrial Biological Resources with Implementation of Finegayan Cantonment/AAFB Family Housing (Alternative) E with Route 15 LFTRC (Alternative 1), and IT/COMM Infrastructure

$^{(2)}$ Only species for which there would be a significant impact.

Cultural Resources

Adverse effects to historic properties and impacts to other cultural resources of cultural importance resulting from the implementation of Alternatives E and 1 would be similar to the combined effects and impacts of Finegayan Cantonment/Family Housing Alternative A with Route 15 LFTRC Alternative 1 discussed in Section 6.1.2.1. Additional effects and impacts could also result from the construction of the IT/COMM links for these alternatives.

Table 6.1.2-39 lists 11 known archaeological sites within the IT/COMM lines PDIA. One of the sites, including portions of NWF, is eligible for listing in the NRHP. Ten archaeological sites are not eligible for listing in the NRHP. A literature review indicated that there are also areas that were not previously surveyed that have a potential for buried cultural resources along Routes 1, 4, 5, 15, and 17.

**Legend:** GHPI = Guam Historic Properties Inventory; NRHP = National Register of Historic Places; NA = not applicable; NRHP criterion A = eligible because they are associated with events that have made a significant contribution to the broad pattern of history, criterion D = eligible for potential to yield information important in prehistory or history.

**Notes:**
†Not all sites recorded within the project areas have received official GHPI numbers, although they have been documented as part of previous surveys.
*Map Numbers from Welch (2009) and Welch (2010).
**The Guam SHPO concurs with this recommendation (Guam SHPO correspondence dated July 2 and September 17, 2014 [RC2013-0853]).

One structure eligible for listing in the NRHP, North Field, is located within the potential impacted area. No TCPs have been identified in the potential impacted areas for the IT/COMM lines.

The installation of IT/COMM links between Alternative E and the LFTRC Alternative 1 has the potential to cause adverse effects from excavation and soil removal to two historic properties, including one NRHP-eligible archaeological sites (see Table 6.1.2-39) and one NRHP-eligible structure (North Field). Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the remaining areas. No TCPs would be directly affected by the construction of the IT/COMM links.

No direct or indirect adverse effects are anticipated to occur due to operation of the IT/COMM utilities as these lines would be buried and there would be no change in use, and no effects to the setting.
The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. To the degree possible, impacts to historic properties and other resources of cultural importance would be avoided during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, potential minimization and mitigation measures may include data recovery and monitoring during construction. However, final mitigation will be determined after completion of the consultation process outlined in the PA. With the implementation of these measures and processes as outlined in the 2011 PA, additive impacts associated with IT/COMM would be reduced to a level below significance.

Ground Transportation

The travel demand modeling methodology for the combination of alternatives was defined and directed by the DoD and the FHWA to provide detailed off-base (external) roadway and intersection analysis for one representative pairing (the modeled combination) of each cantonment/family housing alternative with one of the LFTRC site alternatives.

The modeled combination for Cantonment/Family Housing Alternative E included a pairing with LFTRC Alternative 5 (see Section 3.12). Although Alternative 5 was used for the modeled combination, the results allowed for a thorough qualitative assessment of impacts associated with the other cantonment/family housing and LFTRC alternative combinations as well. Modeling results for this scenario indicate that weekday a.m. peak hour vehicle traffic related to the proposed action is generated solely by operations at the cantonment/family housing area. LFTRC-related traffic would occur prior to the start of weekday a.m. peak hour (8:00 a.m.) and may coincide with the weekday p.m. peak hour (4:30 p.m. to 5:30 p.m.) (see Section 5.1.12). Operations of the LFTRC would increase traffic on the off-base (external) roadway segments and intersections that comprise the most direct route between the main cantonment gate and the LFTRC gates by approximately 38 vehicles (measured in passenger car equivalents) (see Table 5.1.12-2 in Chapter 5). LFTRC-related traffic represents an insubstantial amount of traffic (less than 5%) along the route. This minimal incremental increase in traffic volumes would not adversely affect LOS on roadways or at intersections along the route. The relative contribution from LFTRC traffic to the off-base (external) roadway segment and intersection impacts of each cantonment/family housing alternative would be minimal and would not vary appreciably with any LFTRC pairing (Alternative 1, 2, 3, 4, or 5). Therefore, the impacts to off-base (external) roadway segments and intersections would be essentially the same for Alternative E with Alternative 1, Alternative E with Alternative 2, 3, or 4, and Alternative E with Alternative 5. A qualitative discussion of the potential effects of LFTRC-related traffic is provided for each combination.

Travel routes from Finegayan Cantonment / AAFB Housing (Alternative E) to the LFTRC Alternatives are shown in Figure 6.1.2-5 and would be the same as for Alternative A as shown in Figure 6.1.2-1. Pairing Alternative E with Alternative 1 may result in a slight increase in vehicles (less than 5%) on roadway segments and at intersections that comprise the most direct route between the Alternative E Main Gate and the Alternative 1 gate, and a slight decrease in vehicles compared to the modeled combination Alternative E Main Gate and the Alternative 5 gate (see Figure 6.1.2-1). This minimal incremental increase or decrease in traffic volumes would not adversely affect LOS on roadways or at intersections along the route.
Figure 6.1.2-5

Notes: *Includes impacts to roadway segments in at least one direction during one (or both) weekday a.m. or p.m. peak hours.
** Indicates an impact that would not occur under Year 2030 Alternative A Conditions.

Roadway Segment Operations

A capacity analysis was conducted to determine potential impacts to the off-base (external) roadway network during weekday a.m. and p.m. peak hours. The v/c ratio and LOS for each study roadway segment was compared to the baseline conditions to determine if any significant impacts would occur. The detailed results of the roadway segment analysis are provided in their entirety in Appendix F.

The addition of traffic generated by the proposed action would result in a potentially significant impact on eight study roadway segments in at least one direction during the weekday a.m. and/or weekday p.m. peak hours:

- Route 1, from Route 3 to Route 34. This study roadway segment currently operates at acceptable LOS E with a v/c ratio of 0.99 in the northbound/eastbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.01 in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative E Conditions, this study roadway segment would continue to operate at LOS F with a v/c ratio of 1.06. The proposed action would increase traffic on this study roadway segment by approximately 130 vehicles during the weekday p.m. peak hour. This 5.1% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact in the northbound/eastbound direction on this study roadway segment during the weekday p.m. peak hour. A similar impact was identified on this study roadway segment under Year 2030 Alternative A Conditions.
• Route 1, from Route 34 to Route 16. This study roadway segment currently operates at acceptable LOS E with a v/c ratio of 0.96 in the northbound/eastbound direction during the weekday p.m. peak hour under Existing Conditions. This study roadway segment would operate at acceptable LOS E with a v/c ratio of 0.97 in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative E Conditions, this study roadway segment would degrade to unacceptable LOS F with a v/c ratio of 1.03. Therefore, the proposed action would result in a significant impact in the northbound/eastbound direction on this study roadway segment during the weekday p.m. peak hour. A similar impact was identified on this study roadway segment under Year 2030 Alternative A Conditions.

• Route 3, from Route 3A/9 to Finegayan Main Gate. This study roadway segment currently operates at acceptable LOS B with a v/c ratio of 0.64 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would operate at acceptable LOS C with a v/c ratio of 0.75 in the southbound/westbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative E Conditions, this study roadway segment would degrade to unacceptable LOS F with a v/c ratio of 1.30. Therefore, the proposed action would result in a significant impact on this study roadway segment in the southbound/westbound during the weekday a.m. peak hour. A similar impact was identified on this study roadway segment under Year 2030 Alternative A Conditions.

• Route 3, from Finegayan Main Gate to Secondary Gate. This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.09 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.24 in the southbound/westbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative E Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.41. The proposed action would increase traffic on this study roadway segment by approximately 128 vehicles during the weekday p.m. peak hour. This 12.3% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact on this study roadway segment in the southbound/westbound direction during the weekday a.m. peak hour. A similar impact was identified on this study roadway segment under Year 2030 Alternative A Conditions.

• Route 3, from Secondary Gate to Route 28. This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.23 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would operate at LOS F with a v/c ratio of 1.36 in the southbound/westbound during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative E Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.52. The proposed action would increase the traffic on this study roadway segment by approximately 120 vehicles during the weekday a.m. peak hour. This 10.7% increase in traffic is greater than the 5.0% threshold of significance.

During the weekday p.m. peak hour, this study roadway segment currently operates at acceptable LOS D with a v/c ratio 0.81 in the northbound/eastbound direction and acceptable LOS B with a v/c ratio of 0.67 and southbound/westbound directions hour under Existing conditions. This study roadway segment would continue to operate at acceptable LOS E with a v/c ratio of 0.91 and LOS C with a v/c ratio of 0.74 in the northbound/eastbound and southbound/westbound directions.
directions, respectively, during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative E Conditions, this study roadway segment would degrade to unacceptable LOS F with a v/c ratio of 1.14 in the northbound/eastbound direction and 1.08 in the southbound/westbound direction during the weekday p.m. peak hour. Therefore, the proposed action would result in a significant impact on this study roadway segment in the southbound/westbound directions during the weekday a.m. and p.m. peak hours, and in the northbound/eastbound direction during the weekday p.m. peak hour. A similar impact was identified on this study roadway segment under Year 2030 Alternative A Conditions.

- **Route 3, from Route 28 to South Finegayan Main Gate.** This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.07 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would operate at unacceptable LOS F with a v/c ratio of 1.25 in the southbound/westbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative E Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.32. The proposed action would increase traffic on this study roadway segment by approximately 109 vehicles during the weekday p.m. peak hour. This 5.2% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact in the southbound/westbound direction on this study roadway segment during the weekday a.m. peak hour. A similar impact was identified on this study roadway segment under Year 2030 Alternative A Conditions.

- **Route 3, from South Finegayan Main Gate to Route 1.** This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 2.11 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. Construction of roadway improvements (i.e., signalization of the intersections at Guam Regional Medical City and Okkodo High School and provision of an additional southbound through lane on Route 3) would increase the capacity of this roadway segment. However, despite the fact that these improvements would be constructed prior to Year 2030, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.35 in the southbound/westbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative E Conditions, this study roadway segment would continue to operate at unacceptable LOS F with a v/c ratio of 1.42. The proposed action would increase traffic on this study roadway segment by approximately 110 vehicles during the weekday a.m. peak hour. This 5.1% increase in traffic exceeds the 5.0% threshold of significance. Therefore, the proposed action would result in a significant impact in the southbound/westbound direction on this study roadway segment during the weekday a.m. peak hour. A similar impact was identified on this study roadway segment under Year 2030 Alternative A Conditions.

- **Route 28, from Chalan Balako to Route 3.** This study roadway segment currently operates at unacceptable LOS F with a v/c ratio of 1.08 in the southbound/westbound direction during the weekday a.m. peak hour under Existing Conditions. This study roadway segment would continue to operate at LOS F with a v/c ratio of 1.48 in the southbound/westbound direction during the weekday a.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative E Conditions, this study roadway segment would continue to operate at LOS F with a v/c ratio of 1.57 in the southbound/westbound direction during the weekday a.m. peak hour. The proposed action would increase the traffic on this study roadway segment by approximately 62 vehicles during the weekday a.m. peak hour. This 5.5% increase in traffic is greater than the 5.0% threshold of significance.
During the weekday p.m. peak hour, this study roadway segment currently operates at acceptable LOS B with a v/c ratio of 0.68 in the northbound/eastbound direction under Existing Conditions. This study roadway segment would operate at acceptable LOS E in the northbound/eastbound direction during the weekday p.m. peak hour under Year 2030 Baseline Conditions. Under Year 2030 Alternative E Conditions, this study roadway segment would degrade to operate at unacceptable LOS F with a v/c ratio of 1.05 in the northbound/eastbound direction during the weekday p.m. peak hour. Therefore, the proposed action would result in a significant impact on this study roadway segment in the southbound/westbound direction during the weekday a.m. peak hour and in the northbound/eastbound direction during the weekday p.m. peak hour. A similar impact was identified on this study roadway segment under Year 2030 Alternative A Conditions.

Significant impacts were identified for all impacted roadway segments. Potential mitigation measures for the impacted roadway segments would be similar in scope and scale to those identified in Section 6.1.2.1. Specifically, to reduce impacts to less than significant levels on these study roadway segments, the following potential mitigation measures may be implemented:

- **Potential Mitigation Measure Fin-AAFB-Roads-1**: Implement Potential Mitigation Measure Fin-Roads-1. With implementation of Potential Mitigation Measure Fin-Roads-1, traffic operations on Route 1, from Route 3 to Route 34 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-AAFB-Roads-2**: Implement Potential Mitigation Measure Fin-Roads-2. With implementation of Potential Mitigation Measure Fin-Roads-2, traffic operations on Route 1, from Route 34 to Route 16 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-AAFB-Roads-3**: Implement Potential Mitigation Measure Fin-Roads-3. With implementation of Potential Mitigation Measure Fin-Roads-3, traffic operations on Route 3, from Route 3A/9 to Finegayan Main Gate would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-AAFB-Roads-4**: Implement Potential Mitigation Measure Fin-Roads-4. With implementation of Potential Mitigation Measure Fin-Roads-4, traffic operations on Route 3, from Finegayan Main Gate to Finegayan Residential Gate would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-AAFB-Roads-5**: Implement Potential Mitigation Measure Fin-Roads-5. With implementation of Potential Mitigation Measure Fin-Roads-5, traffic operations on Route 3, from Finegayan Residential Gate to Route 28 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-AAFB-Roads-6**: Implement Potential Mitigation Measure Fin-Roads-6. With implementation of Potential Mitigation Measure Fin-Roads-6, traffic operations on Route 3, from Route 28 to South Finegayan Main Gate would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)
• Potential Mitigation Measure Fin-AAFB-Roads-7: Implement Potential Mitigation Measure Fin-Roads-7. With implementation of Potential Mitigation Measure Fin-Roads-7, traffic operations on Route 3, from South Finegayan Main Gate to Route 1 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

• Potential Mitigation Measure Fin-AAFB-Roads-8: Implement Potential Mitigation Measure Fin-Roads-8. With implementation of Potential Mitigation Measure Fin-Roads-8, traffic operations on Route 28, from Chalan Balako to Route 3 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

The final list of implementable mitigation measures will be dependent on the selected alternative or combination of alternatives and based on project-level technical studies, to be conducted after the alternative or combination of alternatives is selected. FHWA will conduct all NEPA documentation efforts and any associated resource consultations as specific mitigation measures are proposed.

**Intersection Operations**

Intersection analysis was conducted to determine potential impacts to the off-base (external) intersections during weekday a.m. and p.m. peak hours. The LOS for each study intersection was compared to the baseline conditions to determine if any significant impacts would occur. An impact summary is provided in Table 6.1.2-40. The detailed results of the intersection analysis are provided in their entirety in Appendix F.

The addition of traffic generated by the proposed action would potentially result in a significant impact at ten study intersections during the weekday a.m. and/or weekday p.m. peak hours.

• **Route 3 / Route 3A.** This one-way stop-controlled study intersection currently operates at acceptable LOS B with 12.9 seconds of delay and would continue to operate at acceptable LOS C with 16.1 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative E Conditions, this study intersection would degrade to unacceptable LOS F with 56.4 seconds of delay. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour. No impacts were identified at this study intersection under Year 2030 Alternative A Conditions.

• **Route 3 / 9 / Chalan Santa Anita.** This two-way stop-controlled study intersection currently operates at acceptable LOS C with 16.3 seconds of delay and would operate at acceptable LOS E with 36.4 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative E Conditions, this study intersection would degrade to unacceptable LOS F with greater than 180.0 seconds of delay. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour. A similar impact was identified at this study intersection under Year 2030 Alternative A Conditions.

• **Route 3 / Royal Palm Drive.** This two-way stop-controlled study intersection currently operates at acceptable LOS C with 16.3 seconds of delay and would operate at acceptable LOS E with 36.4 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative E Conditions, this study intersection would degrade to unacceptable LOS F with 54.1 seconds of delay. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m.
a.m. peak hour. A similar impact was identified at this study intersection under Year 2030 Alternative A Conditions.

- **Route 1 / Route 3.** This signalized study intersection currently operates at LOS F and would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. During the weekday p.m. peak hour this study intersection currently operates at LOS E with 70.8 seconds of delay and would continue to operate at LOS E with 63.4 seconds of delay during the weekday a.m. and p.m. peak hours, respectively, under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative E Conditions, this study intersection would continue to operate at LOS F with greater than 180.0 seconds of delay and the proposed action would add more than 50 vehicles to this poorly performing intersection during the weekday a.m. peak hour. During the weekday p.m. peak hour the intersection would degrade to operate at unacceptable LOS F with 83.0 seconds of delay. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. and p.m. peak hours. A similar impact was identified at this study intersection under Year 2030 Alternative A Conditions.

- **Route 1 / Route 27.** This signalized study intersection currently operates at acceptable LOS E with 70.3 seconds of delay and would operate at unacceptable LOS F with 118.3 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative E Conditions, this study intersection would continue to operate at unacceptable LOS F with 121.6 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour. A similar impact was identified at this study intersection under Year 2030 Alternative A Conditions.

- **Route 1 / Route 26.** This signalized study intersection currently operates at acceptable LOS D with 27.9 seconds of delay and would operate at acceptable LOS E with 87.6 seconds of delay during the weekday p.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative E Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay and 154.7 seconds of delay during the weekday a.m. and p.m. peak hours, respectively under Year 2030 Baseline Conditions. Under Year 2030 Alternative E Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay and 160.9 seconds of delay during the weekday a.m. and p.m. peak hours, respectively. The project would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. and p.m. peak hours. A similar impact was identified at this study intersection under Year 2030 Alternative A Conditions.
- **Route 16 / Route 10A.** This signalized study intersection currently operates at unacceptable LOS F and would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday a.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative E Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay. The project would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday a.m. peak hour. A similar impact was identified at this study intersection under Year 2030 Alternative A Conditions.

- **Route 1 / Route 14A.** This signalized study intersection currently operates at unacceptable LOS F with 156.1 seconds of delay during the weekday p.m. peak hour under Existing Conditions. This study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay during the weekday p.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative E Conditions, this study intersection would continue to operate at unacceptable LOS F with greater than 180.0 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday p.m. peak hour. A similar impact was identified at this study intersection under Year 2030 Alternative A Conditions.

- **Route 1 / Route 10A.** This signalized study intersection currently operates at acceptable LOS E with 62.6 seconds of delay and would operate at unacceptable LOS F with 139.3 seconds of delay during the weekday p.m. peak hour under Existing Conditions and Year 2030 Baseline Conditions, respectively. Under Year 2030 Alternative E Conditions, this study intersection would continue to operate at unacceptable LOS F with 144.7 seconds of delay. The proposed action would add more than 50 vehicles to this poorly performing intersection. Therefore, the proposed action would result in a significant impact on this study intersection during the weekday p.m. peak hour. A similar impact was identified at this study intersection under Year 2030 Alternative A Conditions.

Significant impacts were identified for all impacted intersections. Potential mitigation measures for the impacted intersections would be similar in scope and scale to those identified in Section 6.1.2.1. Specifically, to reduce impacts to less than significant levels on these study intersections, the following potential mitigation measures may be implemented:

- **Potential Mitigation Measure Fin-AAFB-Int-1:** Implement Potential Mitigation Measure Fin-Int-1. With implementation of Potential Mitigation Measure Fin-Int-1, traffic operations at Route 3 / 9 / Chalan Santa Anita would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-AAFB-Int-2:** Implement Potential Mitigation Measure Fin-Int-2. With implementation of Potential Mitigation Measure Fin-Int-2, traffic operations at Route 3 / Royal Palm Drive would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

- **Potential Mitigation Measure Fin-AAFB-Int-3:** Implement Potential Mitigation Measure Fin-Int-3. With implementation of Potential Mitigation Measure Fin-Int-3, traffic operations at Route 1 / Route 3 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)
• Potential Mitigation Measure Fin-AAFB-Int-4: Implement Potential Mitigation Measure Fin-Int-4. With implementation of Potential Mitigation Measure Fin-Int-4, traffic operations at Route 1 / Route 27 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

• Potential Mitigation Measure Fin-AAFB-Int-5: Implement Potential Mitigation Measure Fin-Int-5. With implementation of Potential Mitigation Measure Fin-Int-5, traffic operations at Route 1 / Route 26 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

• Potential Mitigation Measure Fin-AAFB-Int-6: Implement Potential Mitigation Measure Fin-Int-6. With implementation of Potential Mitigation Measure Fin-Int-6, traffic operations at Route 16 / Route 27 would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

• Potential Mitigation Measure Fin-AAFB-Int-7: Implement Potential Mitigation Measure Fin-Int-7. With implementation of Potential Mitigation Measure Fin-Int-7, traffic operations at Route 16 / Route 10A would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

• Potential Mitigation Measure Fin-AAFB-Int-8: Implement Potential Mitigation Measure Fin-Int-8. With implementation of Potential Mitigation Measure Fin-Int-8, traffic operations at Route 1 / Route 14A would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

• Potential Mitigation Measure Fin-AAFB-Int-9: Implement Potential Mitigation Measure Fin-Int-9. With implementation of Potential Mitigation Measure Fin-Int-9, traffic operations at Route 1 / Route 10A would improve and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

A significant impact would also occur at Route 3 / Route 3A. Implementation of Potential Mitigation Measure Fin-AAFB-Int-1 would improve conditions at this intersection and the significant adverse impact would be mitigated to less than significant levels. Therefore, this impact is considered to be significant but mitigable. (SI-M)

The final list of implementable mitigation measures will be dependent on the selected alternative or combination of alternatives and based on project-level technical studies, to be conducted after the alternative or combination of alternatives is selected. FHWA will conduct all NEPA documentation efforts and any associated resource consultations as specific mitigation measures are proposed.

Transit Conditions

Transit conditions under Alternative E with Alternative 1 would be similar to those described in Section 6.1.2.1 for Alternative A with Alternative 1.

Pedestrian and Bicycle Conditions

Pedestrian and bicycle conditions under Alternative E with Alternative 1 would be similar to those described in Section 6.1.2.1 for Alternative A with Alternative 1.

Public Health and Safety

Impacts to public health and safety from the combination of alternatives are related to the travel between the cantonment and the LFTRC. Therefore, impacts to public health and safety associated with the
combination of Alternative E and Alternative 1 would be the same as discussed for Alternative A and B with Alternative 1 in Section 6.1.2.1.

6.1.2.11 Finegayan Cantonment/AAFB Family Housing (Alternative E) with any NAVMAG LFTRC Alternative (alternatives 2, 3, or 4)

Air Quality

The combined air quality impacts would be the same as those described in Section 6.1.2.1. The combined construction island-wide emissions impacts, summarized in Table 6.1.2-1, would be less than significant as a result of this combined alternative.

Terrestrial Biological Resources

Finegayan Cantonment/AAFB Family Housing (Alternative E) with NAVMAG (East/West) LFTRC (Alternative 2)

The additive impacts of implementing cantonment/family housing Alternative E with LFTRC Alternative 2 and the IT/COMM infrastructure are provided in Table 6.1.2-1. Overall, approximately 827 acres (335 ha) of limestone forest, or 4% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 1,148 acres (465 ha) of Overlay Refuge lands, or 5% of the total Overlay Refuge currently present on Guam, would be disturbed. The majority (94%) of the impacts to terrestrial biological resources would occur under Alternative E, with 780 acres (316 ha) of limestone forest disturbed. The proposed IT/COMM alignment contributes very little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Finegayan Cantonment/AAFB Family Housing (Alternative E) with NAVMAG (North/South) LFTRC (Alternative 3)

The additive impacts of implementing cantonment/family housing Alternative E with LFTRC Alternative 3 and the IT/COMM infrastructure are provided in Table 6.1.2-42. Overall, approximately 977 acres (395 ha) of limestone forest, or 5% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 1,423 acres (576 ha) of Overlay Refuge lands, or 7% of the total Overlay Refuge currently present on Guam, would be disturbed. The majority (79%) of the impacts to terrestrial biological resources would occur under Alternative E, with 780 acres (316 ha) of limestone forest disturbed. The proposed IT/COMM alignment contributes very little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Finegayan Cantonment/AAFB Family Housing (Alternative E) with NAVMAG (L-shaped) LFTRC (Alternative 4)

The additive impacts of implementing cantonment/family housing Alternative E with LFTRC Alternative 4 and the IT/COMM infrastructure are provided in Table 6.1.2-43. Overall, approximately 938 acres (380 ha) of limestone forest, or 5% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 1,367 acres (553 ha) of Overlay Refuge lands, or 6% of the total Overlay Refuge currently present on Guam, would be disturbed. The majority (83%) of the impacts to terrestrial biological resources would occur under Alternative E, with 780 acres (316 ha) of limestone forest disturbed.
disturbed. The proposed IT/COMM alignment contributes very little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Cultural Resources

Adverse effects to historic properties and impacts to other cultural resources of cultural importance resulting from the implementation of Alternatives E and 2, 3, or 4 would be similar to the combined effects and impacts of Finegayan Cantonment/Family Housing Alternative A with any NAVMAG LFTRC Alternative (Alternatives 2, 3, or 4) as discussed in Section 6.1.2.2. Additional effects and impacts could also result from the construction of the IT/COMM links for these alternatives.

Table 6.1.2-44 lists 12 known archaeological sites within the IT/COMM lines PDIA for Alternative E and LFTRC Alternatives 2, 3, or 4. One site, a portion of NWF, is eligible for inclusion on the NRHP. Eleven archaeological sites are not eligible for listing in the NRHP. The literature review indicated that there are also areas that were not previously surveyed that have a potential for buried cultural resources along Routes 1, 5, 15, and 17.

</table>

Legend: GHPI = Guam Historic Properties Inventory; NRHP = National Register of Historic Places; NA = not applicable; NRHP criterion A = eligible because they are associated with events that have made a significant contribution to the broad pattern of history, criterion D = eligible for potential to yield information important in prehistory or history.

Notes: †Not all sites recorded within the project areas have received official GHPI numbers, although they have been documented as part of previous surveys.
**Revised to match Guam GHPI forms dated May 28, 2014.
***The Guam SHPO concurs with this recommendation (Guam SHPO correspondence dated July 2 and September 17, 2014 [RC2013-0853]).

The installation of IT/COMM links between the Alternative E and the LFTRC Alternatives 2, 3, or 4 has the potential to result in adverse effects from excavation and soil removal to two historic properties, including one NRHP-eligible archaeological sites (see Table 6.1.2-44) and one NRHP-eligible structure (North Field). Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the remaining area. No TCPs have been identified in the potential impacted areas for the IT/COMM lines.

No direct or indirect adverse effects due to operation of the IT/COMM utilities would occur as these lines would be buried and there would be no change in use, and no effects to the setting.
The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. To the degree possible, impacts to historic properties and other resources of cultural importance would be avoided during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, potential minimization and mitigation measures may include data recovery and monitoring during construction. However, final mitigation will be determined after completion of the consultation process outlined in the PA. With the implementation of these measures and processes as outlined in the 2011 PA, additive impacts associated with IT/COMM would be reduced to a level below significance.

**Ground Transportation**

Alternative E was modeled with Alternative 5 (Section 3.12.1). Pairing Alternative E with Alternative 2, 3, or 4 may result in a slight increase in vehicles (less than 5%) on roadway segments and at intersections that comprise the most direct route between the Alternative E Main Gate and the Alternative 2, 3, or 4 gates, as well as a slight decrease in vehicles on roadway segments and at intersections that comprise the most direct route between the modeled combination Alternative E Main Gate and the Alternative 5 gate (see Figure 6.1.2-6). This minimal incremental increase or decrease in traffic volumes would not adversely affect LOS on roadways or at intersections along the route.

**Roadway Segment Operations**

Impacts and potential mitigation measures for all off-base (external) roadway segments would be the same as those identified in Section 6.1.2.10 (see Table 6.1.2-40). Significant impacts were identified on eight roadway segments. Potential mitigation measures would be feasible at all locations and could reduce the identified significant impacts to less than significant levels. The detailed results of the roadway segment analysis are provided in their entirety in Appendix F.

**Intersection Operations**

Impacts and potential mitigation measures for all intersections would be the same as those identified in Section 6.1.2.10 (see Table 6.1.2-40). Significant impacts were identified at ten intersections. Potential mitigation measures would be feasible at all locations and could reduce the identified significant impacts to less than significant levels. The detailed results of the intersection analysis are provided in its entirety in Appendix F.

**Transit Conditions**

Transit conditions under Alternative E with Alternative 2, 3, or 4 would be similar to those described in Section 6.1.2.1 for Alternative A with Alternative 1.

**Pedestrian and Bicycle Conditions**

Pedestrian and bicycle conditions under Alternative E with Alternative 2, 3, or 4 would be similar to those described in Section 6.1.2.1 for Alternative A with Alternative 1.

**Public Health and Safety**

Impacts to public health and safety from the combination of alternatives are related to the travel between the cantonment and the LFTRC. Therefore, impacts to public health and safety associated with the combination of Alternative E and Alternatives 2, 3, or 4 would be the same as discussed for Alternative A and B with Alternatives 2, 3, or 4 in Section 6.1.2.1.
6.1.2.12 Finegayan Cantonment/AAFB Family Housing (Alternative E) with NWF LFTRC (Alternative 5)

Air Quality

The combined air quality impacts would be the same as those described in Section 6.1.2.1. The combined construction island-wide emissions impacts, summarized in Table 6.1.2-1, would be less than significant as a result of this combined alternative.

Terrestrial Biological Resources

The additive impacts of implementing cantonment/family housing Alternative E with LFTRC Alternative 5 and the IT/COMM infrastructure are provided in Table 6.1.2-45. Overall, approximately 1,027 acres (416 ha) of limestone forest, or 5% of the total limestone forest currently present on Guam, would be disturbed. In addition, approximately 1,446 acres (585 ha) of Overlay Refuge lands, or 7% of the total Overlay Refuge currently present on Guam, would be disturbed. The majority (76%) of the impacts to terrestrial biological resources would occur under Alternative E, with over 780 acres (316 ha) of limestone forest disturbed. The proposed IT/COMM alignment contributes very little to the overall potential impact to terrestrial biological resources. Additive impacts to terrestrial biological resources would be less than significant.

Table 6.1.2-45. Summary of Impacts to Terrestrial Biological Resources with Implementation of Finegayan Cantonment/AAFB Family Housing (Alternative E) with NWF LFTRC (Alternative 5), and IT/COMM Infrastructure

Cultural Resources

Adverse effects to historic properties and impacts to natural resources of cultural importance resulting from the implementation of Alternatives E and 5 would be similar to the combined effects and impacts of Finegayan Cantonment/Family Housing Alternative A with NWF LFTRC Alternative 5 discussed in
Section 6.1.2.3. Additional effects and impacts could also result from the construction of the IT/COMM links for these alternatives.

Table 6.1.2-46 lists 17 known archaeological sites within the IT/COMM lines PDIA. Five of the sites, two artifact scatters, a Japanese defensive complex, a historic encampment, and portions of NWF, are eligible for inclusion in the NRHP. Twelve archaeological sites are not eligible for listing in the NRHP. One structure eligible for listing in the NRHP, North Field, is located within the potential impacted area. No TCPs have been identified in the potential impacted areas for the IT/COMM lines. The literature review indicated that there are also areas that were not previously surveyed that have a potential for buried cultural resources along Routes 1, 5, 15, and 17.

Notes:  
**Revised to match Guam GHPI forms dated May 28, 2014. 
***The Guam SHPO concurs with this recommendation (Guam SHPO correspondence dated July 2 and September 17, 2014 [RC2013-0853]).
The installation of IT/COMM links between Alternative E and the LFTRC Alternative 5 has the potential to result in adverse effects from excavation and soil removal to six historic properties, including five NRHP-eligible archaeological sites (see Table 6.1.2-46) and one NRHP-eligible structure (North Field). Based on an examination of previous investigations and predictive modeling, there is a low potential for NRHP-eligible sites in the remaining areas. No TCPs would be affected by the construction of the IT/COMM links.

No direct or indirect adverse effects due to operation of the IT/COMM utilities would occur as these lines would be buried and there would be no change in use, and no effects to the setting.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. To the degree possible, impacts to historic properties and other resources of cultural importance would be avoided during the planning process. Consultation under the 2011 PA will address potential adverse effects and alternatives to avoid adverse effects. If avoidance is not possible, potential minimization and mitigation measures may include data recovery and monitoring during construction. However, final mitigation will be determined after completion of the consultation process outlined in the PA. With the implementation of these measures and processes as outlined in the 2011 PA, additive impacts associated with IT/COMM would be reduced to a level below significance.

**Ground Transportation**

Alternative A was modeled with Alternative 5 (Section 3.12.1).

**Roadway Segment Operations**

Impacts and potential mitigation measures for all off-base (external) roadway segments under Alternative E with Alternative 5 would be the same as those identified in Section 6.1.2.10 (see Table 6.1.2-40). Significant impacts were identified on eight roadway segments. Potential mitigation measures would be feasible at all locations and could reduce the identified significant impacts to less than significant levels. The detailed results of the roadway segment analysis are provided in their entirety in Appendix F.

**Intersection Operations**

Impacts and potential mitigation measures for all intersections under Alternative A with Alternative 5 would be the same as those identified in Section 6.1.2.10 (see Table 6.1.2-40) for Alternative E with Alternative 1. Potential mitigation measures were identified for all impacted intersections, and if implemented, could reduce the impacts to less than significant levels. Significant impacts were identified at ten intersections. The detailed results of the intersection analysis are provided in its entirety in Appendix F.

**Transit Conditions**

Transit conditions under Alternative E with Alternative 5 would be similar to those described in Section 6.1.2.1 for Alternative A with Alternative 1.

**Pedestrian and Bicycle Conditions**

Pedestrian and bicycle conditions under Alternative E with Alternative 5 would be similar to those described in Section 6.1.2.1 for Alternative A with Alternative 1.
Public Health and Safety

Impacts to public health and safety from the combination of alternatives are related to the travel between the cantonment and the LFTRC. Therefore, impacts to public health and safety associated with the combination of Alternative E and Alternative 5 would be the same as discussed for Alternative A and B with Alternative 5 in Section 6.1.2.1.

6.1.3 Summary of Additive Impacts

Table 6.1.3-1 summarizes the additive impacts to the resources that would be impacted by unique site combinations, as discussed in Section 6.1.2.
This page intentionally left blank.

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>LSI ItCOMM construction would increase potential for short-term increases in stormwater runoff and erosion. The size and nature of the potentially disturbed area would vary marginally depending on the IT/COMM route; and some routes are closer to surface waters and wetlands than others. However, through compliance with the Construction General Permit and Program SWPPP and implementation of a site-specific SWPPPs, and associated erosion control, runoff reduction, and sediment removal BMPs, impacts to surface water resources would be minimized and off-site transport of stormwater runoff would be unlikely except during extreme weather events (i.e., typhoons). These stormwater runoff protection measures would also serve to protect surface water, groundwater, and wetlands from indirect impacts and prevent impacts to nearshore waters. Because the IT/COMM lines would primarily be located in existing roadways, no direct impacts to wetlands or other waters of the U.S. are anticipated. The potential exposure to direct or indirect impacts at any one location or resource would be short-term, given that construction would not occur simultaneously along the entire IT/COMM route at any one time and construction at any one location would be of relatively short duration. Based on these considerations, the additive impacts of IT/COMM construction activities would be less than significant.</td>

### PUBLIC HEALTH AND SAFETY

- **Alternative 1**
  - Traffic improvements in the Alternative A and B area.
  - Traffic improvements completed in 2012.
  - Increased traffic in areas with no sidewalks would increase the potential for bikers and pedestrians to be involved in a collision.
  - Travel distance between sites is short.
  - Traffic improvements would be minimal.

- **Alternative 2**
  - Traffic improvements in the Alternative A and B area.
  - Traffic improvements completed in 2012.
  - Increased traffic in areas with no sidewalks would increase the potential for bikers and pedestrians to be involved in a collision.
  - Travel distance between sites is short.
  - Traffic improvements would be minimal.

- **Alternative 3**
  - Traffic improvements in the Alternative A and B area.
  - Traffic improvements completed in 2012.
  - Increased traffic in areas with no sidewalks would increase the potential for bikers and pedestrians to be involved in a collision.
  - Travel distance between sites is short.
  - Traffic improvements would be minimal.

- **Alternative 4**
  - Traffic improvements in the Alternative A and B area.
  - Traffic improvements completed in 2012.
  - Increased traffic in areas with no sidewalks would increase the potential for bikers and pedestrians to be involved in a collision.
  - Travel distance between sites is short.
  - Traffic improvements would be minimal.

- **Alternative 5**
  - Traffic improvements in the Alternative A and B area.
  - Traffic improvements completed in 2012.
  - Increased traffic in areas with no sidewalks would increase the potential for bikers and pedestrians to be involved in a collision.
  - Travel distance between sites is short.
  - Traffic improvements would be minimal.

### ENVIRONMENTAL JUSTICE AND THE PROTECTION OF CHILDREN

No additive Environmental Justice impacts under any combination of alternatives.
6.2 COLLECTIVE IMPACTS INCLUDING 2010 ROD-RELATED ACTIONS

Collective impacts refer to the impacts of the entire Marine Corps relocation to Guam, and comprise those impacts resulting from implementation of the proposed action combined with the 2010 ROD-Related Actions not affected by the 2012 Roadmap Adjustments. Such collective impacts would customarily be presented as part of a traditional cumulative impacts analysis, which considers the incremental impact of the proposed action when added to other past, present, and reasonably foreseeable projects. This SEIS, however, presents these impacts in this manner to further the public's understanding of the total direct, indirect, and cumulative impacts resulting from the proposed relocation. This collective impacts analysis facilitates both the analysis of the mitigation associated with the overall relocation effort and the development of associated environmental compliance documentation and consultations, such as those required under section 7 of the ESA. While this presentation of collective impacts represents a departure from the customary organization of an EIS, procedurally it represents the first step in the required cumulative impacts analysis for this SEIS (Chapter 7).

6.2.1 2010 ROD-Related Actions

The 2010 ROD-Related Actions that were not affected by the 2012 Roadmap Adjustments were discussed in detail in the 2010 Final EIS (Volume 1, Chapter 2: Overview of Proposed Actions and Alternatives, Section 2.2: Marine Corps Relocation - Guam, pages 2-7 through 2-17), and are summarized below in Table 6.2.1-1.
## Table 6.2.1. 2010 ROD-Related Actions

The following sections summarize the impacts to each resource from the 2010 ROD-Related Actions listed above and discussed in Volume 2 of the 2010 Final EIS. Impacts in the following sections are discussed in the future tense although it should be noted that some impacts resulting from construction and operations are occurring, or may have already occurred.

6.2.1.1 Geological and Soil Resources

As discussed in the 2010 Final EIS (Volume 2: Marine Corps - Guam, Chapter 3: Geological and Soil Resources, Section 3.2.2: Alternative 1, pages 3-34 to 3-49; Volume 6: Related Actions, Chapter 5: Geological and Soil Resources, Section 5.2.6.2: Alternative 2, pages 5-19 to 5-20), construction activities will include clearing, grading and grubbing, demolition of existing road pavement, earthwork, and landscaping on a total of approximately 383.6 acres (155.2 ha). Cut soil will be used as fill material whenever possible to minimize impacts to soil. Soil types that will be disturbed are not agriculturally productive, and BMPs will be utilized to minimize soil erosion. Proposed developments are located on relatively flat areas that are not subject to slope instability. There will be no adverse impacts to the sinkhole at North Ramp. Established procedures will be implemented to minimize topsoil loss, compaction, and erosion from training activities.

6.2.1.2 Water Resources

As discussed in the 2010 Final EIS (Volume 2: Marine Corps - Guam, Chapter 4: Water Resources, Section 4.2.2: Alternative 1, pages 4-84 to 4-118) there will be no direct impacts to surface waters or wetlands. Construction activities will result in the potential for an increase in stormwater runoff, erosion, and sedimentation, and the increase in impervious area will result in a minor increase in stormwater intensities and volume. LID measures and BMPs will be implemented to protect surface water and groundwater quality. There will be direct impacts to nearshore waters from the wharf improvement projects at Apra Harbor, and nearshore water quality will be temporarily impacted during the dredging process in Inner Apra Harbor. In addition, construction activities at Apra Harbor could result in runoff...
that could be transported to or directly released to nearshore waters. Strict adherence to all applicable legal requirements will reduce potential impacts to surface waters, groundwater, nearshore waters, and wetlands.

As discussed in the 2010 Final EIS (Volume 6: Related Actions, Chapter 6: Water Resources, Section 6.2.6.2: Alternative 2, page 6-34), construction activities associated with the Hagåtña (Agaña) Bridge #1 replacement will cause an unavoidable loss of 0.2 acre (0.06 ha) of waters of the U.S. However, this impact will be minimized through (1) use of construction and source control BMPs cooperatively developed by FHWA and GEPA, and (2) improved hydraulic conveyance under the proposed bridge/box culvert replacement, which will serve to reduce erosion and sedimentation downstream. Through the development and implementation of site-specific construction BMPs, coordination with regulatory agencies, and adherence to applicable orders, laws, and regulations relating to water quality, construction activities will result in less than significant impacts to surface water, groundwater, and nearshore waters. In the operational phase, no impacts to floodplains are anticipated. Diversion of drainage from one watershed to another will be avoided. Roadway-specific BMPs will be included in the project planning, design, and construction. All operations will be implemented in accordance with all applicable federal, local, and military orders, laws, and regulations. Therefore, impacts to surface water, groundwater, and nearshore waters from the 2010 ROD-Related Actions will be less than significant.

6.2.1.3 Air Quality

As discussed in the 2010 Final EIS (Volume 2: Marine Corps - Guam, Chapter 5: Air Quality, Section 5.2.2: Alternative 1, pages 5-18 to 5-29; Volume 6: Related Actions, Chapter 7: Air Quality, Section 7.2.6.3: Alternative 2, pages 7-48 to 7-54), construction and operation of the facilities will result in air emissions. Construction emissions will include SO₂, CO, PM₁₀, PM₂.₅, NOₓ, VOC, and CO₂; however, construction will be short-term and localized. Aircraft and helicopter engines emit criteria pollutants during all phases of operation. There will also be vehicle emissions during training exercises. Air emissions associated with both construction and operation of the 2010 ROD-Related Actions will be well below the significance criteria of 250 tpy for all criteria air pollutants.

6.2.1.4 Noise

The 2010 Final EIS (Volume 2: Marine Corps - Guam, Chapter 6: Noise, Section 6.2.2: Alternative 1, pages 6-23 to 6-42; Volume 6: Related Actions, Chapter 8: Noise, Section 8.2.6.1: Alternative 1, pages 8-12 to 8-40) discusses noise impacts from construction and operation of the 2010 ROD-Related Actions. Construction noise will be temporary, and heavy equipment that will generate the highest noise levels will not be used consistently enough to exceed the USEPA guidance level of 75 dBA for more than one hour beyond DoD installation boundaries. Additionally, terrain and distance from construction activities will lessen noise impacts to sensitive receptors outside of the construction areas. There may be localized noise for brief periods from temporary increases in truck traffic, but there will not be an adverse noise impact to human health, neighboring communities, or within installations. Airfield operations will increase noise for some additive residences within the 60-70 dBA DNL zones, but there will not be a significant impact to human health or hearing. Non-firing training will include new sources of ground-based noise from vehicle use on existing roads, the convoy course, and the Advanced Motor Vehicle Operator’s Course in the maneuver training area, but these noise characteristics are similar to standard commercial vehicles. Most maneuver training will occur within the core of the maneuver training area, and noise setbacks will be established along the boundaries with the urban interface. Abatement measures for noise impacts associated with roadway projects are included as part of the project, where feasible.
6.2.1.5 Airspace

As discussed in the 2010 Final EIS (Volume 2: Marine Corps - Guam, Chapter 7: Airspace, Section 7.2.2: Alternative 1, pages 7-13 to 7-15), there will be an increase in total aircraft based at AAFB as well as associated aircraft operations. However, there will be no change to any of the approach and departure patterns associated with the airports/airfields at AAFB. The existing SUA will be used to conduct aircrew flight training, and low level training routes and landing zones will be established over Guam following VFR rules and procedures, and will not impact established flight paths. There will be no restrictions on access to, and no effect on, the use of Guam International Airport. In addition, there will be no effect on airport or airfield arrival and departure traffic flows due to the increase in military aircraft.

6.2.1.6 Land and Submerged Land Use

All of the non-roadway 2010 ROD-Related Actions will be constructed and operated at existing DoD facilities (2010 Final EIS, Volume 2: Marine Corps - Guam, Chapter 8: Land and Submerged Land Use, Section 8.2.3: Alternative 1, pages 8-59 to 8-75). There will be no change in land or submerged land use, no new public access restrictions, and all activities are consistent with land and submerged land use plans. Impacts from construction of the roadway projects, as discussed in the 2010 Final EIS (Volume 6: Related Actions, Chapter 10: Land and Submerged Land Use, Section 10.2.6.1: Alternative 1, page 10-12) will be typical of a public works maintenance project, with occasional disruption to business/commercial and tourist facilities. A Traffic Management Plan will be developed for implementation during construction activities.

6.2.1.7 Recreational Resources

As discussed in the 2010 Final EIS (Volume 2: Marine Corps - Guam, Chapter 9: Recreational Resources, Section 9.2.2: Alternative 1, pages 9-19 to 9-26; Volume 6: Related Actions, Chapter 11: Recreational Resources, Section 11.2.6.2, pages 11-9 to 11-10), construction of the 2010 ROD-Related Actions will result in an increase in construction-related vehicles on the roadways. This increase may cause delay for persons attempting to gain access to recreational resources. Construction activities will be short-term and localized. A Traffic Management Plan will be developed for implementation during roadway construction activities. All airfield and training operations will occur on DoD property. The training area at Andersen South will result in the loss of use of the Andersen South roads by joggers and walkers by fencing off the property and the addition of gates, however this resource is not unique to the region and there are comparable resources available in the adjoining properties.

6.2.1.8 Terrestrial Biological Resources

As discussed in the 2010 Final EIS (Volume 2: Marine Corps - Guam, Chapter 10: Terrestrial Biological Resources, Section 10.2.2: Alternative 1, pages 10-90 to 10-169), a total of 7.5 acres (3 ha) of primary limestone forest and 131 acres (53 ha) of secondary or disturbed limestone forest at AAFB will be removed. However, much of this forest area is not contiguous (i.e., the sum of the impacted forested area is from a number of different projects that are not collocated) or is adjacent to developed and previously disturbed areas.

As discussed in the 2010 Final EIS (Volume 6: Related Actions, Chapter 12: Terrestrial Biological Resources, Section 12.2.6.1: Alternative 1, pages 12-36 to 12-42), negligible direct impacts to aquatic habitats (approximately 0.15 acres [0.06 ha]) would occur from the replacement of Hagåtña Bridge #1 with reinforced concrete. Indirect impacts to aquatic habitats would be limited to potential sedimentation along the 260 feet (79 m) between the bridge and the river’s terminus. Impacts to potential habitat for special-status species from the 2010 ROD-Related Actions are not significant.
Construction activities will displace wildlife from potentially suitable habitat in the project areas; however, construction activities are short-term and localized, and displaced species are abundant and are expected to repopulate suitable portions of the project areas upon completion of construction.

No vegetation will be cleared during training operations. In addition, with implementation of established BMPs and mitigation measures identified in the 2010 Final EIS, the introduction or spread of invasive species is not anticipated.

6.2.1.9  Marine Biological Resources

As discussed in the 2010 Final EIS (Volume 2: Marine Corps - Guam, Chapter 11: Marine Biological Resources, Section 11.2.2: Alternative 1, pages 11-73 to 11-113) and as covered in the Marine Biological Opinion (USFWS 2010), the only direct impacts to marine biological resources would be associated with wharf improvement construction activities at Apra Harbor. Marine flora, invertebrates, and associated EFH will not be appreciably modified from existing conditions, and impacts will be short-term and minor. Increases of construction-related vessel movements could result in localized disturbance and displacement of fish species as a result of the potential for increased turbidity, increased benthic sedimentation, impacts to eggs and larvae in the upper water column, and seasonal disturbances to spawning coral reef and pupping scalloped hammerhead sharks. These impacts will be short-term, periodic, and localized. Green sea turtles will be protected by postponing in-water construction activities when green sea turtles are detected in the area. Additionally, green sea turtles are highly mobile and it is expected that dredging and pile driving activities will deter green sea turtles from closely approaching work areas.

Impacts to marine biological resources from roadway projects, as summarized in Table 13.2-8 of the 2010 Final EIS (Volume 6: Related Actions, Chapter 13: Marine Biological Resources, page 13-39), would include indirect impacts during construction and operation from increased runoff and potential for sedimentation of marine waters.

6.2.1.10  Cultural Resources

The 2010 ROD-Related Actions consist of construction at North Ramp, South Ramp, and a North Gate on AAFB, development of the non-firing training range complex at Andersen South, wharf upgrades and construction at Naval Base Guam, and construction of ammunition magazines and aviation training at the NAVMAG. These specific project areas were intensively investigated as described in the 2010 Final EIS (Volume 2: Marine Corps - Guam, Chapter 12: Cultural Resources, Section 12.1, pages 12-1 to 12-38. The 2010 ROD-Related Actions, as discussed in the 2010 Final EIS (Volume 2: Marine Corps - Guam, Chapter 12: Cultural Resources, Section 12.2.2: Alternative 1, pages 12-41 to 12-54; Volume 6), would potentially affect 11 historic properties, including seven within the airfield and training areas at AAFB, two within NAVMAG, and two within the training areas at Andersen South (Table 6.2.1-2). No adverse effects would occur to historic properties at Apra Harbor or Naval Base Guam. No historic architectural properties eligible for the NRHP would be adversely affected. Less than significant impacts would occur due to the use of the existing foot trail at NAVMAG. There would be no impacts to TCPs or resources of cultural importance from the implementation of these actions.

Additional 2010 ROD-Related Actions include the five roadway projects along Route 1, which are discussed in Volume 6 of the 2010 Final EIS (Volume 6: Related Actions, Chapter 14: Cultural Resources, Section 14.2.6.1: Alternative 1, page 14-19). The intersection improvement and pavement strengthening projects would not impact cultural resources. Hagåtña (Agaña) Bridge is a historic property. However, the bridge will be reconstructed in its historic location, and mitigation will preserve the only
remaining historic attributes and features contributing to the bridge’s NRHP eligibility; therefore, FHWA found that, with mitigation, the project will have no adverse effect on Hagåtña (Agaña) Bridge.

Notes: †Not all sites recorded within the project areas have received official GHPI numbers, although they have been documented as part of previous surveys.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements for the overall relocation action. Broadly, the 2011 PA includes processes to share information, consider views of the public, and develop mitigation measures when historic properties may be adversely affected.

More specifically, the 2011 PA established a process for the review and analysis of potential effects to historic properties and other cultural resources and provides measures for mitigating adverse effects to NRHP-eligible or listed archaeological sites, consulting on new projects and initiating additional identification efforts, and resolving impacts due to loss of access to areas of cultural significance or culturally important natural resources. To the degree possible, direct and indirect impacts to historic properties and natural resources of cultural importance would be avoided or minimized during the planning process. If avoidance is not possible, anticipated mitigation measures to resolve adverse effects to historic properties and reduce adverse impacts to cultural resources resulting from the implementation of the 2010 ROD-Related Actions include the following: (1) identifying and evaluating other properties as applicable, (2) developing a mitigation plan, (3) consulting with PA Signatories and Concurring Parties if requested, (4) conducting data recovery or other appropriate mitigation, (5) submitting data recovery or similar mitigation reports to SHPO for review before finalizing, (6) preparing public educational materials in English and Chamorro, and (7) enforcing construction contractor measures.
6.2.1.11 Visual Resources

The 2010 ROD-Related Actions will occur at existing DoD facilities and will not represent a major visual change from existing conditions (2010 Final EIS, Volume 2: Marine Corps - Guam, Chapter 13: Visual Resources, Section 13.2.2: Alternative 1, pages 13-62 to 13-69). Publicly accessible views into these areas are limited due to distance or dense vegetation.

Roadway projects, as discussed in the 2010 Final EIS (Volume 6: Related Actions, Chapter 15: Visual Resources, Section 15.2.6.1: Alternative 1, pages 15-8 to 15-26) will not have an adverse impact on the existing visual environment. Replacement of the Hagåtña (Agaña) Bridge will include mitigation measures that address the aesthetics of the bridge, which will increase the visual quality.

6.2.1.12 Ground Transportation

Impacts to ground transportation from implementation of the 2010 ROD-Related Actions will be limited to the construction period. There may be potential temporary congestion associated with the delivery of construction materials and equipment, removal of construction debris, and parking for construction workers. Construction will be short-term, temporary, and localized. A Traffic Management Plan will be developed for implementation during roadway construction activities.

6.2.1.13 Marine Transportation

As discussed in the 2010 Final EIS (Volume 2: Marine Corps - Guam, Chapter 14: Marine Transportation, Section 14.2.2: Alternative 1, pages 14-10 to 14-15) additional container and break-bulk cargo ships will be required to transport equipment and supplies necessary for the construction of the 2010 ROD-Related Actions. Additionally, the dredging of Sierra Wharf will require transportation of dredged material over a period of 6 to 9 months. There has been a steady and substantial decline in the number of commercial vessels visiting the Port of Guam from 1995 through 2012. The number of vessels associated with the 2010 ROD-Related Actions is well below the total number of vessels visiting the Port of Guam in 1995, which had the highest number of vessel visits between 1995 through 2012. As the additional number of vessels is much less than the difference between the number of current (2012) vessel visits and the number of vessel visits in 1995, there will be no impacts to marine transportation from construction of the 2010 ROD-Related Actions.

6.2.1.14 Utilities

As discussed in the 2010 Final EIS (Volume 1: Overview of Proposed Actions and Alternatives, Chapter 2: Overview of Proposed Actions, Section 2.2: Marine Corps Relocation - Guam, pages 2-7 to 2-17), the 2010 ROD-Related Actions not affected by the 2012 Roadmap Adjustments will require localized and relatively small increased demand for utilities.

Primary utility needs will be local to Apra Harbor. The total utility requirements for the 2012 Roadmap Adjustments proposed action, including those from the 2010 ROD-Related Actions, have been included in the SEIS utilities assessments. Utilities will be installed at facilities using BMPs and standard construction and operation procedures and requirements to minimize impacts to existing utilities. The existing utilities can accommodate the additional usage at the new facilities.
6.2.1.15  Socioeconomics and General Services

The 2010 Final EIS (Volume 2: Marine Corps - Guam, Chapter 16: Socioeconomics and General Services, Section 16.2.2: Proposed Action and Section 16.2.3: Land Acquisition Impacts, pages 16-73 to 16-147) assesses impacts based on an increase in population and land acquisition. There will be no increase in population attributable specifically to construction and operation of the 2010 ROD-Related Actions. Additionally, the 2010 ROD-Related Actions will not require land acquisition.

6.2.1.16  Hazardous Materials and Waste

As discussed in the 2010 Final EIS (Volume 2: Marine Corps - Guam, Chapter 17: Hazardous Materials and Waste, Section 17.2.2: Alternative 1, pages 17-38 to 17-55), construction of the 2010 ROD-Related Actions will result in the use and disposal of more hazardous materials. There is the potential for an inadvertent spill, release, or leak of hazardous materials. Hazardous materials will be handled and disposed of per applicable BMPs and SOPs.

6.2.1.17  Public Health and Safety

As discussed in the 2010 Final EIS (Volume 2: Marine Corps - Guam, Chapter 18: Public Health and Safety, Section 18.2.2: Alternative 1, pages 18-13 to 18-23; Volume 6: Related Actions, Chapter 19: Public Health and Safety, Section 19.2.9.1: Alternative 1, pages 19-17 to 19-18), there may be impacts associated with UXO and traffic accidents, as well as impacts to noise, water quality, and air quality. These impacts will be minimal and will be limited primarily to the construction period, which will be short-term and localized. UXO may be encountered during construction or during operations.

Training activities associated with the 2010 ROD-Related Actions have minimal potential to impact public health and safety. The public will be notified prior to training activities, and all training activities will occur within established on-base training areas. Specific and documented procedures will be implemented to reduce the potential for interaction between the public and training personnel and to ensure that the public is not endangered by training activities.

6.2.1.18  Environmental Justice and the Protection of Children

As discussed in the 2010 Final EIS (Volume 2: Marine Corps - Guam, Chapter 19: Environmental Justice and the Protection of Children, Section 19.2.2: Alternative 1, pages 19-11 to 19-18; Volume 6: Related Actions, Chapter 20: Environmental Justice and the Protection of Children, Section 20.2.8: Summary of Impacts, page 20-20), there will be an increase in construction-related noise, traffic, and safety concerns during construction of the 2010 ROD-Related Actions. These impacts will be short-term, temporary, and localized, and will not disproportionately impact minority or low-income populations or children. A Traffic Management Plan will be prepared and implemented during roadway construction. Completion of the roadway projects will have a beneficial impact due to improved and safer roadway infrastructure.

6.2.1.19  Summary of Impacts Associated with the 2010 ROD-Related Actions

Table 6.2.1-3 summarizes the potential impacts to each resource from the 2010 ROD-Related Actions.
Table 6.2.1-3. Summary of Potential Impacts from Implementation of the 2010 ROD-Related Actions

<table>
<thead>
<tr>
<th>Resource</th>
<th>Impact</th>
</tr>
</thead>
<tbody>
<tr>
<td>Geological and Soil Resources</td>
<td>Total disturbed acreage from construction is approximately 383.6 acres (155.2 ha). There is one sinkhole in the vicinity of the North Ramp that will not be adversely impacted.</td>
</tr>
<tr>
<td>Water Resources</td>
<td>BMPs will be utilized to minimize the indirect impacts to groundwater and surface water. There will be no loss of wetlands. There will be direct but temporary impacts to nearshore waters from dredging at Inner Apra Harbor.</td>
</tr>
<tr>
<td>Air Quality</td>
<td>Increase in emissions, including SO₂ and hot spot PM, CO, and MSATs concentrations, will be below applicable impact significance thresholds.</td>
</tr>
<tr>
<td>Noise</td>
<td>Construction noise will be temporary and will be within existing DoD property boundaries. Noise from airfield operations and training functions will not have a significant or adverse impact to human health or hearing.</td>
</tr>
<tr>
<td>Airspace</td>
<td>There will be an increase in total aircraft based at AAFB and associated aircraft operations; however, there will be no change to any of the approach and departure patterns associated with the airports/airfields at AAFB and there will be no restrictions on access to, and no effect on the use of Guam International Airport Route There will be no measurable change in airspace requirements or management procedures.</td>
</tr>
<tr>
<td>Land and Submerged Land Use</td>
<td>Activities are compatible with existing land uses. No significant impacts identified for airfield activities, non-firing training, or waterfront activities.</td>
</tr>
<tr>
<td>Recreational Resources</td>
<td>During construction, there may be increased traffic congestion due to the presence of construction vehicles. Noise generated from proposed training activities will be consistent with noise from existing operations and will not diminish user experience at recreational areas.</td>
</tr>
<tr>
<td>Terrestrial Biological Resources</td>
<td>Clearing of a total of 384 acres (155 ha) of vegetation, 7.5 acres (3 ha) of which is primary limestone forest at AAFB. Disturbance to and loss of habitat for special-status species. With implementation of established BMPs and mitigation measures identified in the 2010 Final EIS, the introduction or spread of invasive species is not anticipated.</td>
</tr>
<tr>
<td>Marine Biological Resources</td>
<td>No direct impacts to special-status species will occur, although indirect impacts could occur because of increased marine traffic associated with delivery of construction materials and equipment. Impacts to EFH would be short-term and localized.</td>
</tr>
<tr>
<td>Cultural Resources</td>
<td>Direct adverse effects to 11 historic properties.</td>
</tr>
<tr>
<td>Visual Resources</td>
<td>Facilities will be within existing DoD properties and will not represent a major change over the existing visual conditions.</td>
</tr>
<tr>
<td>Ground Transportation</td>
<td>Potential temporary congestion associated with the delivery of construction materials and equipment, removal of construction debris, and parking for construction workers.</td>

6.2.2 Resources with No Additional Collective Impact from the 2010 ROD-Related Actions

The 2010 Final EIS identified no impacts to the following resources from the 2010 ROD-Related Actions:

- Airspace
- Land and Submerged Land Use
- Visual Resources
- Socioeconomics and General Services

Therefore, the impacts of the proposed action (as described in Chapters 4 and 5 and Section 6.1) represent the total collective impacts of the Marine Corps relocation for these resources, and they are not discussed further in this section.

6.2.3 Resources with Collective Impacts Common to All Alternative Site Combinations

Several additional resources would be subject to collective impacts associated with the proposed action and the 2010 ROD-Related Actions, but the impacts would not be uniquely related to alternative site combinations. Many of these collective impacts are associated with the construction phase, which would result in short-term, localized impacts. An analysis of the collective impacts associated with implementation of the proposed action (regardless of selected alternative site combinations) and the 2010 ROD-Related Actions is presented below.

6.2.3.1 Geological and Soil Resources

Collective impacts to soil resources would result from the increased acreage of disturbance, including clearing, grading and grubbing, earthwork, and landscaping. BMPs would be utilized to minimize soil erosion. Therefore, the collective impact to soil resources would be less than significant.

There are numerous sinkholes and depressions identified, as well as the potential for sinkholes and depressions at several of the proposed alternative locations. There is one sinkhole identified at North Ramp. For any sinkholes discovered before or during construction, BMPs would include compliance with the requirements of 22 GAR Chapter 10, § 10106. With implementation of these BMPs, no adverse impacts from sinkholes would occur due to construction. Therefore, the collective impact associated with sinkholes and depressions would be less than significant.

There would not be a collective impact on topography. Although the 2010 ROD-Related Actions include clearing, grading and grubbing, demolition of existing road pavement, earthwork, and landscaping on a total of approximately 383.6 acres (155.2 ha), there would not be a significant amount of cut and fill that would permanently alter the topography of the area. Although there is not a collective impact to topography, impacts to topography remain significant due to the amount of cut and fill at the LFTRC alternatives.

6.2.3.2 Water Resources

Neither the proposed action nor the 2010 ROD-Related Actions would directly impact surface waters or wetlands; therefore, there would be no collective direct impact to these resources. Although there would be direct impacts to nearshore waters for the 2010 ROD-Related Actions, there would be no direct impacts to nearshore waters from construction or operation of the proposed action; thus, the collective direct impact to nearshore waters would result only from the ROD-Related Actions.

Stormwater runoff protection measures, including compliance with Construction General Permit requirements and other regulations and implementation of BMPs, LID, and a Program SWPPP and site-specific SWPPPs, would minimize the collective indirect impacts. Groundwater demand from the NGLA
would be substantially less than the sustainable yield, but there would be localized significant impacts to the NGLA that would be mitigated, as well as less than significant impacts to the overall NGLA. Induced civilian and construction/DoD workforce growth during construction and operation of the proposed action would increase demand for wastewater treatment and disposal of generated wastewater. This would result in significant short-term indirect collective impacts to nearshore waters during the construction phase, but upgrades to the currently non-compliant WWTP(s) treatment systems (as required by their current NPDES permits) would mitigate indirect impacts during operation to less than significant.

6.2.3.3 Air Quality

Since the analysis described in Chapters 4 and 5 was performed for the maximum potential adverse effect, the forecasts of location-specific traffic and construction activities impacts would remain representative under this and other combined alternatives. Therefore, the localized mobile source concentration collective impacts would be less than significant.

6.2.3.4 Recreational Resources

Collective impacts to recreational resources from implementation of the proposed actions and the 2010 ROD-Related Actions could result from both the increase in the workforce and associated increased use of recreational resources during the construction phase. During construction there may be increased traffic congestion that delays access to recreational resources due to the presence of construction vehicles. However, there are no additional operational impacts beyond those discussed in Chapter 4. Any hindrance of access caused by construction activities would be short-term and localized, and the collective impacts to recreational resources would be less than significant.

6.2.3.5 Marine Biological Resources

Although there are direct impacts related to construction in Inner Apra Harbor for the 2010 ROD-Related Actions, the proposed action would not create any additional collective impact.

Total vessel traffic is not anticipated to exceed historical maximum levels, and BMPs would be implemented to minimize impacts to water quality from vessel operations. Therefore, the collective impacts to marine biological resources would be less than significant.

However, consultation with the NMFS under section 7 of the ESA was concluded on the entire proposed action including the remaining proposed construction in Inner Apra Harbor associated with the 2010 Final EIS and the proposed action included in this Final SEIS. The DON previously completed a consultation related to the Guam and CNMI Military Relocation EIS in 2010, and the DON continues to operate under the 2010 BO for the listed marine species addressed under that consultation (i.e., sea turtles). However, since completion of the 2010 consultation, the threatened scalloped hammerhead shark and three species of threatened coral (Acropora globiceps, Acropora retusa, and Seriatopora aculeata) that may occur within the project area have been listed. The DON determined that these newly listed species could occur in the vicinity of the proposed action, and accordingly, the DON requested a reinitiation of informal consultation to address potential effects to these newly listed species. Consultation with the NMFS concluded with a letter of concurrence on May 18, 2015. The NMFS considered the information in the DON’s EIS/OEIS (2010), the Draft SEIS (2014), and consultation requests, as well as the best scientific information available about the biology and expected behaviors of the ESA-listed marine species and agreed with the DON conclusion that the proposed action is not likely to adversely affect scalloped hammerhead sharks or the three ESA-listed corals. NMFS also agreed that the proposed action would have no effect on critical habitat. NMFS provided five conservation recommendations that they deemed prudent to include in their letter of concurrence. The DON will consider adoption of one or more of these
conservation recommendations and will address them in the ROD for this proposed action.

6.2.3.6 Ground Transportation

As discussed in Section 6.2.1.12, impacts to ground transportation from implementation of the 2010 ROD-Related Actions will be limited to the construction period. During the construction period, temporary and intermittent transportation impacts would result from truck movements, as well as construction worker vehicles traveling to and from the site. Construction-related impacts generally would not be considered significant due to their temporary nature and limited, finite duration. Therefore, any collective impact to ground transportation from implementation of the proposed action and the 2010 ROD-Related Actions would be less than significant.

6.2.3.7 Marine Transportation

Implementation of the proposed action and the 2010 ROD-Related Actions concurrently would increase the amount of vessel traffic in Apra Harbor during construction. The combined total number of predicted vessel visits to Apra Harbor during construction is 514 vessel visits (127 barges of dredge spoils + 387 cargo ships [242 breakbulk +145 containers]). This, combined with the predicted number of background vessel visits within the range of analysis shown in Section 4.1.13, would not exceed the recent maximum number of annual vessel visits (in FY 1995). Because the annual number of vessels visiting the Port of Guam has decreased by 2,289 vessels over the period of FY 1995 to FY 2012, it is expected that the additional predicted annual number of vessels visiting the Port of Guam would result in a less than significant impact on marine transportation. Therefore, the collective impact from construction of the proposed action and the 2010 ROD-Related Actions would be less than significant.

6.2.3.8 Utilities

Utility demands associated with the proposed action are primarily associated with the cantonment/family housing alternatives. To meet these demands, the proposed action included development of a well field and upgrades to electrical lines, as discussed in Section 2.2.3. Utility demands resulting from implementation of the 2010 ROD-Related Actions, LFTRC alternatives, and cantonment/family housing alternatives are of the same magnitude regardless of alternative, and would be met by the existing utility infrastructure and utility upgrades associated with the proposed action. Therefore, the collective impact to utilities from implementation of the proposed action and the 2010 ROD-Related Actions would be less than significant.

6.2.3.9 Hazardous Materials and Waste

As discussed in Section 6.2.1.16, construction of the 2010 ROD-Related Actions will result in an increase in the use of hazardous materials and disposal of hazardous waste. To avoid inadvertent hazardous substance spills, releases, or leaks, hazardous materials will be used and disposed of in accordance with applicable SOPs and BMPs. The proposed action would also result in an increase in the use of hazardous materials and disposal of hazardous waste regardless of location. With implementation of BMPs and SOPs, the collective impact associated with the use, storage, and disposal of hazardous materials and waste would be less than significant.
6.2.3.10 Public Health and Safety

Collective impacts associated with construction of the proposed action and the 2010 ROD-Related Actions could occur during periods when there would be overlap in construction. The increase of the civilian workforce that would potentially occur regardless of action alternative may create a collective impact to health care services, as well as impacts associated with UXO, traffic accidents, noise, water quality, and air quality. This collective impact would be limited to the construction period, which would be short-term and localized. Therefore, the collective impact to public health and safety during construction would be less than significant.

6.2.3.11 Environmental Justice

Collective impacts associated with construction of the proposed action and the 2010 ROD-Related Actions could occur during periods when there would be overlap in construction. As discussed above in Public Health and Safety, the increase of the civilian workforce may create a collective impact to health care services, which would disproportionately impact low-income populations. Construction would be short-term and localized; therefore, the collective impacts would be less than significant.

6.2.4 Collective Impacts Associated with Unique Site Combinations

Collective impacts include the combination of the impacts discussed for each of the cantonment/family housing alternatives, the LFTRC alternatives, and the impacts associated with the 2010 ROD-Related Actions. This section provides an analysis of potential collective impacts of different combinations of site alternatives (i.e., Alternatives A through D for cantonment/family housing and Alternatives 1 through 5 for the LFTRC) and the impacts of the 2010 ROD-Related Actions. The resource areas that would be affected by collective actions associated with unique site combinations are Noise, Terrestrial Biological Resources, and Cultural Resources. The subsections below provide a comparison of the collective impacts to Noise, Terrestrial Biological Resources, and Cultural Resources associated with the unique site combinations and the 2010 ROD-Related Actions.

6.2.4.1 Noise

Collective noise impacts would be limited to those associated with the LFTRC. Alternative 1 is located in the same geographic region as Andersen South. Noise-producing activities at Andersen South include aviation training, military operations on urban terrain training, breacher house training, use of the HG range, and convoy training. However, the noise contours generated by the 2010 ROD-Related Actions do not overlap with the LFTRC contours. Therefore, the collective noise impact associated with the 2010 ROD-Related Actions and the combination of any of the cantonment/family housing alternatives with Alternative 1 would be less than significant.

Collective impacts would also occur from implementation of any of the three NVMAG LFTRC alternatives (Alternative 2, 3, or 4) due to the noise-generating activities of the 2010 ROD-Related Actions occurring at NVMAG, coupled with the LFTRC noise from Alternatives 2, 3, or 4. Noise producing activities include aviation and ground-based training. However, the noise contours generated by the 2010 ROD-Related Actions do not overlap with the LFTRC contours. Therefore, the collective noise impact associated with the 2010 ROD-Related Actions and the combination of any of the cantonment/family housing alternatives with any of the NVMAG LFTRC alternatives would be less than significant. Collective impacts would also occur due to the noise generating activities of the 2010 ROD-Related Actions occurring at NWF (aircraft operations) coupled with the LFTRC noise from Alternative 5. In addition, ground-based training at NWF (use of the demolition range where Marine Corps and Air Force units detonate cratering charges) would also contribute to collective noise impacts.
Figure 6.2.4-1 shows noise contours for aviation training, the demolition range, and the LFTRC. The aviation and LFTRC noise would not overlap at any location off-base. The demolition noise contours and the LFTRC noise contours overlap, but the “average busy day” noise generated by the demolition range contours only occurs twice per year. Therefore, the collective impact associated with the 2010 ROD-Related Actions and the combination of any of the cantonment/family housing alternatives with Alternative 5 would be less than significant.

6.2.4.2 Terrestrial Biological Resources

The collective impacts due to implementation of the cantonment/family housing alternatives, LFTRC alternatives, IT/COMM lines, and the 2010 ROD-Related Actions would be equal to the combined effects and impacts of each. Terrestrial biological resources investigations for these actions are discussed in Sections 6.1, 6.2.1.8, and Chapters 4 and 5. A summary of the collective impact to terrestrial biological resources is provided in Table 6.2.4-1. Comparisons of the potential alternative combinations are discussed below.

Alternative C and Alternative 1 would have the greatest total impacts to limestone forest (primary and secondary combined): 1,485 acres (601 ha). This would be approximately 8% of the limestone forest found on federal lands on Guam. Similarly, Alternative C, combined with Alternatives 5, 3, and 4 would have the next greatest impacts to limestone forest, at 1,431 acres (579 ha), 1,399 acres (566 ha), and 1,360 acres (550 ha), respectively. Any combination of alternatives that include Alternative D would have the lowest total impact to limestone forest, and Alternative D combined with Alternative 2 would have the lowest impact: 316 acres (128 ha). This would be approximately 1.7% of the limestone forest found on federal lands on Guam. No significant impacts to limestone forest would occur with implementation of the ITT/COMM infrastructure portion of any alternative combination.

With respect to Overlay Refuge lands, any combination of alternatives that include Alternative A would have the greatest potential impact. Specifically, Alternative A with Alternative 3 would have the greatest total impact to Overlay Refuge lands at 1,608 acres (651 ha), or 7% of the lands. Similar to impacts to limestone forest, any combination of alternatives that include Alternative D would also have the lowest total impact to limestone forest. Specifically, Alternative D with Alternatives 1 or 2 would have the lowest impact at 153 acres (62 ha) or <1% of the lands.

All alternative combinations would have significant impacts to ESA-listed special-status species, and only six alternative combinations would not have significant impacts to Guam-listed special-status species: Alternatives C or D when combined with Alternatives 1, 2, or 5.

- Direct impact - conversion to developed areas.
- Only species for which there would be a significant impact.
6.2.4.3 Cultural Resources

The collective effects and impacts due to the implementation of the cantonment/family housing alternatives, LFTRC alternatives, IT/COMM lines, and the 2010 ROD-Related Actions would be equal to the combined effects and impacts of each. Cultural resources investigations for these actions are discussed in Sections 6.1, 6.2.1.10, and Chapters 4 and 5. A summary of the collective impact to cultural resources is provided in Table 6.2.4-2.

The 2011 PA, as discussed in Section 3.10.2, establishes a program alternative for complying with NHPA Section 106 requirements. For a description of the program alternative for NHPA Section 106 compliance refer to Section 6.2.1.10 of this chapter.

CHAPTER 7
CUMULATIVE EFFECTS

7.1 CUMULATIVE EFFECTS ANALYSIS FOR 2010 FINAL EIS COMPARED TO SEIS

There are many frameworks for conducting cumulative effects analysis. USEPA and GEPA have endorsed the use of the approach described in Defining Cumulative Impact, Approach and Guidance (California Department of Transportation, USEPA, and FHWA 2005) that identifies eight steps for a cumulative effects analysis. This methodology and general CEQ guidance for assessing cumulative effects is as described in the 2010 Final EIS (Volume 7, Chapter 4: Cumulative Effects, Sections 4.1: Consistency with Cumulative Effects Analysis Guidance and Section 4.2: Cumulative Effects Methodology, pages 4-1 to 4-4).

There are inherent differences between the cumulative effects analysis prepared for the 2010 Final EIS and this SEIS:

- The cumulative effects study area for this SEIS is limited to Guam and specifically excludes the CNMI because there is no proposed action for the CNMI in this SEIS. Further, the four training ranges proposed on Tinian that were included in the 2010 ROD are on hold pending completion of a separate environmental study, the CNMI Joint Military Training EIS/OEIS.

- In accordance with the 2012 Roadmap Adjustments, the magnitude of the Marine Corps proposed action, as described in Section 1.2 of this SEIS, is reduced from that proposed in the 2010 Final EIS. This SEIS is focused on Marine Corps cantonment/family housing and LFTRC alternatives and supporting infrastructure. The relocating population resulting from implementation of the proposed action is substantially less than that proposed in the 2010 Final EIS, and the population growth and construction schedule are much more gradual than originally projected. The adaptive program management that was proposed to monitor the impact of rapid construction and peak population growth of the 2010 Final EIS proposed action is not warranted for this SEIS proposed action.

- The 2010 Final EIS considered the cumulative effect of the preferred alternative only. This SEIS assesses multiple alternatives.

- The alternatives assessed in this cumulative effects chapter are the proposed action alternatives plus the 2010 ROD-Related Actions. These alternatives are referred to as the “collective action alternatives” and were introduced in Section 6.2, Collective Impacts Including 2010 ROD-Related Actions.

- The list of recently completed, present, and reasonably foreseeable projects was updated subsequent to the completion of the 2010 Final EIS.
Both the 2010 Final EIS and this SEIS address cumulative effects under a separate chapter. For this SEIS, Chapters 4 and 5 present impact analyses for components of the collective action alternatives, with the collective action alternatives addressed in Chapter 6. Although cumulative effects could have been addressed in Chapter 6, it was determined that a separate chapter focused specifically on cumulative effects would improve readability of this SEIS.

7.2 METHODOLOGY - EIGHT STEP APPROACH OVERVIEW

The following is a list of the Defining Cumulative Impact, Approach and Guidance (California Department of Transportation, USEPA, and FHWA 2005) “eight steps” applied to perform the cumulative effects analysis for this SEIS:

1. Identify resources to consider in the cumulative effect analysis.
2. Define the study area for each resource.
3. Describe the current health and historical context for each resource.
4. Describe direct and indirect impacts of the proposed project that might contribute to a cumulative effect.
5. Identify other reasonably foreseeable future actions that affect each resource.
6. Assess potential cumulative effects.
7. Report the results.
8. Assess the need for mitigation.

Each of these steps is addressed in subsequent sections to guide the reader through the analysis.

7.3 STEPS 1 TO 3: IDENTIFY RESOURCES TO INCLUDE, DEFINE THE STUDY AREA, DESCRIBE CURRENT HEALTH AND HISTORICAL CONTEXT FOR EACH RESOURCE

Steps 1 through 3 of the cumulative effect analysis are as follows:

1. **Identify resources to consider in the cumulative effect analysis.** Chapters 4, 5 and 6 of this SEIS address the direct and indirect impacts of the proposed action components and the collective action alternatives on various resources: geological and soil resources, water resources, air quality, noise, airspace, land and submerged land use, recreation, terrestrial biological resources, marine biological resources, cultural resources, visual resources, ground transportation, marine transportation, utilities, socioeconomics and general services, hazardous materials and waste, public health and safety, and environmental justice and the protection of children. Although the magnitude of the proposed action is reduced in this SEIS relative to the 2010 Final EIS, the proposed action represents the largest action being proposed for Guam in the recent past and foreseeable future; therefore, all of the environmental resources listed are considered in this cumulative effect analysis.

2. **Define the study area.** The study area is Guam-wide for each resource. The cumulative effects study area also includes submerged lands encompassed by the LFTRC SDZ. As mentioned in Section 7.1 of this SEIS, Tinian and other CNMI locations are not included in this SEIS cumulative effects study area.
3. **Describe the current health and historical context for each resource.** The 2010 Final EIS (Volume 7, Chapter 1: Introduction, Section 1.3: Historical Perspective-Guam, pages 1-6 to 1-13) provides an overview of key events in the history of Guam that have influenced the island’s environmental resources. These are not repeated in this SEIS. The trends in, and factors affecting, resource health island-wide (i.e., human behavior and natural events) have played a role in the existing conditions (or affected environment) of each resource as described in Chapters 3 through 6 of this SEIS. Existing conditions were updated to incorporate new information identified subsequent to the 2010 Final EIS. A summary of findings is reported under each resource in Section 7.6 under the subsections entitled, *Current Health and Historical Context*. In addition to the long-term historical perspective, recent trends in resource health and resiliency are considered. These recent trends are based on a review of recently completed projects, as listed in Section 7.5. Recently completed projects may include changes in zoning policy or increased regulatory control over construction that would impact the future health trend of a resource and the potential for cumulative effects.

7.4 **STEP 4: DESCRIBE DIRECT AND INDIRECT IMPACTS OF THE PROPOSED PROJECT THAT MIGHT CONTRIBUTE TO CUMULATIVE EFFECTS**

Typically, cumulative effects analysis is conducted on the action alternatives; however, in this SEIS the direct and indirect impact analysis and the cumulative effects analysis is based on the “collective action alternatives” impacts, as described in Chapter 6.2 of this SEIS.

Due to the complexity of the proposed action and the large number of alternatives, this SEIS presents the direct and indirect impacts of the two key components of the proposed action in separate chapters: Chapter 4 (cantonment/family housing alternatives) and Chapter 5 (LFTRC alternatives). The impacts of the pairing of each cantonment/family housing alternative with each of the LFTRC alternatives plus the impacts of IT/COMM infrastructure connecting the two components are presented in Section 6.1 as “additive” impacts. Additive impacts were identified (see Table 6.1.3-1) for the following resources under each pairing of cantonment/family housing and LFTRC alternative: geological and soil resources (LSI), water resources (LSI), noise (LSI), air quality (LSI), terrestrial biology (LSI), cultural resources (SI-M), ground transportation (SI/SI-M), socioeconomics and general services (land acquisition) (LSI), hazardous materials and waste (LSI), and public health and safety (LSI). No “additive” impact was identified for the remaining resource areas.

Section 6.2 of this SEIS acknowledges that there may be additional impacts that result from the proposed action in conjunction with the 2010 ROD-Related Actions (summarized in Table 6.2.1-1). The combined alternatives, as described in Section 6.1 plus the 2010 ROD-Related Actions (Section 6.2), are referred to in this chapter (Chapter 7) as “collective action alternatives.” More detail on the collective action alternative impacts is provided in Section 6.2. In summary, no impacts were identified for the collective action alternatives for airspace, land and submerged land use, visual resources, or socioeconomics and general services. Significant impacts were identified for terrestrial biology and cultural resources for specific collective action alternatives. Less than significant impacts were identified for the remaining resources.

To facilitate the cumulative effects analysis, the highest level of significance identified under each resource for each collective action alternative is the significance impact level used in the cumulative effects analysis, as shown on Table 7.4-1. This simplification provides a “worst-case” assessment of the potential adverse impacts of each collective action alternative. Construction and operational impacts as
well as direct and indirect impacts were considered in assigning the highest level of significance. If the construction or indirect impact would have a higher level of significant impact on the long-term health or resilience of a resource than the operational or direct impacts, then it is this significance level that is included in the table. It is important to note that there may be short-term high levels of significance reported for the construction phase, but cumulative effects focuses on long-term trends in resource health. For example, short-term impacts to traffic during construction may be significant but would not impact the long-term operation-phase traffic conditions. Similarly, if the 2010 ROD-Related Actions impact was reported at a higher level of significance than the SEIS cantonment/family housing or LFTRC impacts, then the 2010 ROD-Related Action impact is shown in the table. The discussion of these results by resource is presented in Section 7.7, under the heading “Direct and Indirect Impacts of the Collective Action Alternatives That Might Contribute to a Cumulative Effect.” The less than significant impacts identified have potential to contribute to a significant cumulative effect.

Some of the resources have multiple criteria with varying levels of significance and the criteria are listed in Table 7.4-1. Table 7.4-1 is further simplified in Table 7.6-2. The highest level of significance identified in the multiple criteria under each resource becomes the significance level for that resource and is used in this cumulative effects analysis. The result is that each collective action alternative has one reported level of significance for each resource in Table 7.6-2.

As shown in Table 7.4-1, when the impact analysis data is simplified to the highest level of significance for each resource, all of the collective action alternatives would have a significant level of impact (SI or SI-M) on multiple resources. No single collective action alternative stands out as having the least environmental impact. The 2010 ROD-Related Action impacts are the same for all collective action alternatives.

The naming convention for the collective action alternatives is: cantonment/family housing alternative letter - LFTRC alternative number. For example, collective action alternative “A-1” represents the Finegayan/South Finegayan (Alternative A) paired with the Route 15 LFTRC (Alternative 1).

Legend: LSI = less than significant impact; SI = significant impact; SI-M = significant and mitigable to less than significant.

Impacts that are considered SI or SI-M are shown in Red font. Blue shading = the Preferred Alternative - Finegayan for Cantonment/AAFB for Family Housing (Alternative E) and NWF (Alternative 5) for LFTRC. Cantonment/family housing Alternatives: A= Finegayan, B= Finegayan and South Finegayan, C = AAFB, D = Barrigada. LFTRC Alternatives: 1 = Route 15; 2, 3, and 4 = NAVMAG Alternatives; 5 = NWF. *Significance level related to additive impacts described in Section 6.1.
7.5 **STEP 5: RECENTLY COMPLETED, PRESENT, AND REASONABLY FORESEEABLE FUTURE PROJECTS**

Table 7.5-1 is a list of recently completed, present, and reasonably foreseeable future actions that would be completed within a designated timeframe (2009-2028). As mentioned in Section 7.3, part of the assessment of past trends in resource health includes an assessment of recent trends in resource health and identification of recently completed projects assists with that assessment. The timeframe for the cumulative effect assessment is project-specific. This SEIS cumulative effects timeframe begins 6 years prior to possible implementation (2015) of the proposed action and ends with the anticipated completion of construction (2028). The recently completed project timeline is 2009 to 2013 (the year the affected environment analyses for this SEIS were initiated). The present projects would occur while this SEIS is being prepared (2013-2015) and the reasonably foreseeable projects are anticipated to be operational while the proposed action is being constructed and becomes fully operational (2015-2028). Reasonably foreseeable actions are “sufficiently likely to occur, that a person of ordinary prudence would take it into account in making a decision” (Sierra Club v. Marsh, 976 F.2d 763, 767 (1st Cir. 1992). The approach in this SEIS has been more inclusive of projects than exclusive.

The recently completed, present, and reasonably foreseeable future projects list was developed by updating the 2010 Final EIS list of projects with data from Internet searches and interviews with government agencies. The list includes DoD and non-DoD projects. 2010 ROD-Related Actions are not listed as projects for the cumulative impact analysis because they are included as components of the collective action alternatives in Step 4 of the cumulative effects analysis.

The projects in Table 7.5-1 are organized by geographic area. The projects are assigned an identification code, where the letter represents a geographic area and the number is sequential, for example: North (N-1), Central (C-1), Apra (A-1), and South (S-1). Those projects that are Guam-wide or could not be mapped, based on information available, are listed first in Table 7.5-1 with a G-x identifier, for example G-1. Figures 7.5-1, 7.5-2, 7.5-3, and 7.5-4 show the approximate project locations in the North, Central, Apra, and South regions of Guam, respectively.

    - NAVMAG (North/South) (Alt 3)
    - NAVMAG (L-Shaped) (Alt 4)
- 2010 ROD Related Action (see Figure 1.3-1 for detail)

Note: IT/COMM lines not shown (see Figures 2.6-1 through 2.6-5 for detail).
As shown on Figure 7.5-1, the majority of the projects in the northern area of Guam are on AAFB and very few in the civilian community. The proposed action includes cantonment/family housing alternatives on Finegayan and AAFB, LFTRC alternatives at NWF and east of Andersen South, and school and water well field expansions on AAFB. IT/COMM alternatives associated with the proposed cantonment/family housing and LFTRC alternatives are aligned along existing roadways. The 2010 ROD-Related Actions are the non-live fire training at Andersen South and the Air Combat Element of the Marine Corps at AAFB. No reasonably foreseeable civilian projects would be precluded by any of the collective action alternatives in the northern part of Guam.

The collective action alternatives in central Guam include the following (see Figure 7.5-2): a cantonment/family housing alternative at Barrigada, an LFTRC alternative east of Andersen South and non-live fire training at Andersen South as a 2010 ROD-Related Action. A HG Range is also proposed at Andersen South. There are IT/COMM alternatives associated with the LFTRC and cantonment/family housing alternatives in the area. Non-DoD projects unrelated to the collective action alternatives include roadway improvement projects that are distributed throughout the area, and projects near the airport and in Tumon. No reasonably foreseeable civilian projects would be precluded by any of the collective action alternatives in the central part of Guam; however, there a few current land uses that would be discontinued.

The Apra Harbor area (see Figure 7.5-3) includes the waterfront improvement projects of the 2010 ROD-Related Actions. There are no cantonment/family housing or LFTRC alternatives in the Apra Harbor area; however, there are IT/COMM alignment alternatives that would be aligned along existing roadways (not shown on Figure 7.5-3) in the vicinity of Apra Harbor. No reasonably foreseeable civilian projects would be precluded by any of the collective action alternatives in the Apra Harbor area of Guam.

As shown on Figure 7.5-4, the majority of projects proposed in the southern region of Guam are GovGuam roadway and bridge improvements. The collective action alternatives include various LFTRC configurations associated with NAVMAG. In addition, there would be IT/COMM alignments proposed in the area to support these collective action alternatives. The non-DoD projects are primarily infrastructure improvement projects. No reasonably foreseeable civilian projects would be precluded by any of the collective action alternatives in the southern part of Guam.

The projects that are Guam-wide or not mapped are proposed by GovGuam and consist primarily of infrastructure projects. In some cases, the project site has not been determined. The remaining Guam-wide projects would not be precluded by the collective action alternatives.

The 2010 Final EIS (Volume 7, Chapter 4.3: Recently Completed, Present, and Reasonably Foreseeable Future Actions, pages 4-24 to 4-25) provides additional detail for some of the larger projects, including the Commercial Port Modernization; Pacific Airpower Resiliency, AAFB (formerly known as Intelligence, Surveillance, Reconnaissance, and Strike capability); and Mariana Islands Range Complex MIRC. These descriptions are unchanged.

There were a number of workforce housing projects proposed in anticipation of the H-2B workers that would be brought on-island to support the military relocation as proposed in the 2010 Final EIS, but most of these projects were not constructed or were developed for alternative uses when the construction projects did not materialize. The following sections provide more detail on workforce housing, the DoD Mariana Islands Training and Testing (MITT), and DoD Actions that are not relevant to this SEIS.
7.5.1 Workforce Housing Update

Section 4.1.15 of this SEIS provides a summary of the workforce housing projects. In summary, there was workforce housing to accommodate an estimated 3,700 workers in 2009. Most were located at Harmon Industrial Park. Subsequent to 2009, workforce housing projects were approved or pending approval for an additional capacity of 26,500 workers. Most of these projects were never completed or were converted to rental units. The largest proposal, Ukudu Work Force Village, was initially proposed for 18,000 workers by Younex. A capacity of 1,800 workers was approved and under Phase I of construction, 500 units have been constructed. Phase II would require Younex to fund off-site utility improvements to support the worker population per a Guam Waterworks Association permit condition. There have been some short-term uses of the units for student housing; however, the units are generally vacant.

7.5.2 Mariana Islands Testing and Training

The MITT (project G-23 on Table 7.5-1) is proposed by the U.S Pacific Fleet. An EIS/OEIS is being prepared to evaluate the potential environmental impacts associated with maintaining military readiness training and research, development, testing, and evaluation activities conducted in the MITT study area. The MITT EIS/OEIS is a follow-on study to the MIRC EIS/OEIS, the ROD of which was published in July 2010. The MIRC EIS/OEIS preferred alternative is part of the existing training capability in the MITT EIS/OEIS. The Draft EIS/OEIS was published in September 2013 (NAVFAC Pacific 2013a).

The MITT study area includes the existing MIRC, additional areas on the high seas, and a general transit corridor between Hawaii and MITT where training and testing activities may occur. The MIRC is the only major DON range complex in the MITT study area. The EIS/OEIS supports the renewal of current regulatory permits and authorizations, addresses current training and testing not covered under existing permits and authorizations, and identifies those permits and authorizations necessary to support force structure changes and emerging and future training and testing requirements including those associated with new platforms and weapons systems within the MITT study area, starting in 2015, thereby ensuring critical DoD requirements are met. The MITT study area is predominantly ocean and Guam represents a small part of the total area. Increased training tempo is proposed for the submerged lands that underlie warning area W-517 located south of Guam and small arms firing areas are proposed west of Agat Bay and the Haputo Point area. These proposed actions would restrict public access for recreation during training events. The resource areas addressed in the impact analysis are as follows:

- Sediments and Water Quality
- Air Quality
- Marine Habitats
- Marine Mammals*
- Sea Turtles*
- Marine Birds
- Marine Vegetation
- Marine Invertebrates
- Fish
- Terrestrial Species and Habitats*
- Cultural Resources
- Socioeconomic Resources
- Public Health and Safety
The resources listed above with an asterisk (*) were the primary resources of concern for the cumulative impact analysis. Implementation of the identified past, present, and reasonably foreseeable future actions would result in significant impacts to these resources; however, the contribution of the specific MITT EIS/OEIS no-action and preferred alternatives to the cumulative effects would be low. For example, the impacts of the MITT proposed action on marine mammal and sea turtles were deemed to be minor relative to the mortality or injury due to by catch, commercial ship strikes, entanglement, and ocean pollution. The MITT EIS/OEIS conclusions were not limited to Guam, but encompassed the entire MITT study area. Some characteristics relevant to Guam are summarized below for the two resource areas addressed in detail in the cumulative impact analysis that are relevant to this SEIS.

Sea Turtles: Five species of sea turtles are identified in the MITT study area and the proposed action “may effect, is likely to adversely affect” all five species. No nesting of sea turtles was identified in the study area. Hawksbill turtles are observed around Guam but there are no areas of concentrated occurrence. Green turtles are known to forage around Guam. The MITT proposed action was described as not decreasing the overall fitness of any given population.

Terrestrial Species and Habitats: Conclusions relevant to terrestrial biology include: a) AAFB proposed training is likely to impact Mariana fruit bat, Mariana crow (extirpated), non-ESA listed forest birds, (e.g., Micronesian starling); b) Fena Reservoir training is likely to impact Mariana fruit bat, Mariana common moorhen, Mariana swiftlet, and non-ESA listed forest birds; and c) proposed NMS (referred to as NAVMAG in this SEIS) training is likely to impact Mariana swiftlet, Mariana common moorhen, Mariana fruit bat, vegetation communities, and non-ESA listed forest birds (e.g., yellow bittern). There would be no impact to critical habitat within the Ritidian Unit of the Guam NWR. The EIS/OEIS concludes “although potential impacts on certain bird species from the proposed action could include injury or mortality, impacts are not expected to decrease the overall fitness result in long-term population-level impacts of any given population”(NAVFAC Pacific 2013a).

7.5.3 Marianna Islands Range Complex Airspace

The MIRC Airspace Final Environmental Assessment/Overseas Environmental Assessment (“MIRC EA/Overseas EA”) was published in June 2013 (NAVFAC Pacific 2013b). The document was prepared to specifically address proposed modifications to airspace and sea space within the MIRC. The action alternatives propose expansion of the danger zone and restricted area around Farallon de Medinilla, and creating new airspace warning areas south of Guam and northeast of Saipan. The level of training and testing activities that would occur within the airspace and sea space would remain the same as those assessed in the MIRC EA/Overseas EA’s Finding of No Significant Impact, which was published June 15, 2013. The preferred alternative included: extend Restricted Area R-7201 and danger zone at Farallon de Medinilla to 12 nautical miles (22 km) and designate it as R-7201A; and create new warning areas W-11, W-12, and W-13 to replace ATCAAs 1, 2, and 3. Warning areas W-11 and W-12 are south of Guam and ATCAA 6 that overlies Guam would not be affected by the proposed action.

The four resource areas assessed for direct and indirect impacts were: public health and safety; transportation resources; regional economy; and recreation, and no significant impacts were identified. Based on the MIRC EIS/OEIS cumulative impact analysis and direct impact analysis in the EA/Overseas EA, no cumulative impacts were identified.
7.5.4 **Other DoD Actions Outside of the Study Area**

There are DoD actions that are not included in the cumulative effect assessment because they are located outside of the cumulative effect study area(s). NEPA documents were or are being prepared for the following actions:

- Divert Activities and Exercises EIS (Air Force)
- CNMI Joint Military Training EIS/OEIS (U.S. Pacific Command)

7.6 **STEP 6: ASSESS CUMULATIVE EFFECTS**

The assessment of cumulative effects was conducted in two steps as follows:

**Step 6A:** Assess the potential long-term impacts among the recently completed, present, and reasonably foreseeable future projects.

**Step 6B:** Conduct a cumulative impact analysis of recently completed, present, and reasonably foreseeable future projects in conjunction with collective action alternatives.

7.6.1 **Step 6A: Assess the Potential Long-term Impact of Recently Completed, Present, and Reasonably Foreseeable Future Projects**

Step 6A assesses the potential for each of the recently completed, present, and reasonably foreseeable future projects listed in Table 7.5-1 to have a long-term adverse or beneficial impact on each resource. The resource impacts for each individual project were presumably considered at the time of their approval. BMPs and permit conditions were presumably implemented to negate adverse impacts to resources. The assessment was necessarily qualitative because of the limited amount of information available for most of the projects. The potential impact of each project on each resource was estimated to be either: adverse, beneficial, or negligible for each resource category. Where projects had both beneficial and adverse aspects regarding impacts within a particular resource category, the predominant long-term impacts were considered. When reviewing project-specific data, the following assumptions were made to guide the assignment of adverse and beneficial impacts:

- **Geological and Soil Resources:**
  - Implementation of BMPs would minimize construction impacts and there would not be long-term impacts to geological and soil resources due to construction projects.
  - For DoD projects, BMPs and DoD regulations would be fully implemented.
  - On DoD lands, sinkholes would be avoided and appropriate vegetative and/or physical buffers placed to minimize the potential to adversely impact these resources.
  - For non-DoD projects, erosion control plans would be developed and fully implemented, as required by GovGuam.
  - Bank stabilization, erosion mitigation projects, bridge and roadway repairs would have long term beneficial impacts on soils.
  - Some changes in land use may result in permanent long-term reductions in soil loss and sedimentation of nearby surface waters and wetlands, yielding a beneficial impact; however, project specific information often was not available to make this determination.
  - Large-scale development projects would have an adverse impact on topography.
Water Resources:
- Implementation of site-specific SWPPPs and associated stormwater BMPs would minimize construction impacts and there would be no long-term impacts to water resources due to construction projects.
- The USGS numerical groundwater model used to manage the NGLA and the GWRDG (comprised of agencies and other stakeholders) serve to protect water resources.
- New building construction projects would result in an increase in impervious surfaces that would increase stormwater runoff volume and pollutant loading potential.
- Implementation of LID measures and BMPs for compliance with local and federal requirements would minimize potential impacts to downstream development, sensitive water resources, and ecology.
- Unless project information indicated the presence of wetlands, it was assumed none were or would be affected, directly or indirectly.
- Any improvements to wastewater or potable water infrastructure would have a beneficial impact on water resources.
- Municipal landfills are heavily regulated and managed to protect water. The assumption is new landfills would not impact water resources.

Air Quality:
- Induced traffic or use of fuel-powered stationary equipment associated with operation of a project would have an adverse impact, especially if the project is located within the non-attainment areas.
- Impacts due to construction would not be long-term impacts on the resource.
- Power generation based on fossil fuels would adversely impact air quality.
- Roadway improvement projects would not increase the long-term adverse impacts on air quality, but new roadways, intersections and associated new traffic would impact air quality.

Noise:
- Projects such as airfield operations, aviation training, ground-based training, and/or traffic have the potential to generate operational noise levels that may be incompatible with human activity in the vicinity. The impact would be localized.

Airspace:
- Airport or airfield improvements reflect a planned increase in air traffic with potential adverse impact on airspace.
- Tall facilities that are subject to FAA approval regarding air navigation safety would have an adverse impact.

Land and Submerged Land Use:
- Projects on DoD land are consistent with base planning.
- All off-base projects were approved by GovGuam elected officials, commissions or agencies; therefore, they are consistent with land use policies and objectives.
- Some land uses may be consistent with planning principles but may have siting challenges, such as landfills, power stations, hospitals, and wind turbines. These projects would have an adverse impact.
- Projects that may restrict public access to a community-valued resource would have an adverse impact.
Recreational Resources:
- Projects that create new recreational facilities, such as a new hotel with a golf course, would have a beneficial impact because they expand leisure opportunities and would reduce crowding at other facilities.
- Projects that are population inducing would increase the number of potential users of recreational sites. This is not an adverse impact unless it would lead to overcrowding that exceeds the site’s carrying capacity and enjoyment; however, that level of detail for the projects listed is not available. All population inducing projects would adversely impact recreation assets. Projects that would adversely impact recreational resources include, new subdivisions or workforce housing, new hotels, and new or expanded military missions.

Terrestrial Biological Resources:
- Loss or conversion of native habitat would reduce the potential recovery and survival of ESA-listed species creating an adverse impact.
- Restoration or enhancement of degraded habitat would increase the potential for native species recovery and survival, particularly ESA- and Guam-listed species, and would have a beneficial impact.
- Reductions and management activities (i.e., fencing, removal) of invasive species and/or feral ungulates or their access to habitat would have a beneficial impact.
- Projects involving ground disturbance, such as construction of housing or new and widened roadways, would contribute to an adverse cumulative effect. Projects that are renovations or improvements to existing facilities within the existing facility footprint would have no impact on terrestrial biological resources, such as resurfacing a roadway.

Marine Biological Resources:
- Stormwater and erosion control BMPs would be implemented for all inland projects. There would be minimal direct impact of a cumulative project to the marine environment.
- LID measures, described in Section 4.1.2.2 of this SEIS, would be implemented in accordance with the DoD UFC LID (UFC 3-210-10) and Section 438 of the EISA, and would minimize potential impacts to downstream development, sensitive water resources, and ecology.
- Coastal or nearshore development would have an adverse direct or indirect impact.
- Development on streams or rivers that flow to the ocean would have an adverse impact; however, projects that appear to be corrective actions would have a beneficial impact on the resource.
- Wastewater improvement projects would have a beneficial impact on the resource.
- Population growth-inducing projects would have an adverse impact through recreational pressure and increase demand on wastewater infrastructure. Residential development projects and resort projects would imply an increase in on-island permanent or transient population.
- Changes to submerged land use that would adversely impact species recovery would be an adverse impact.

Cultural Resources:
- Projects that result in adverse effects to historic properties can lead to a cumulative loss of the archaeological and built-historical record that could contribute to an adverse cumulative impact.
- Projects that damage culturally important natural resources can lead to an adverse cumulative impact.
o Projects that lead to reduced access to cultural sites can lead to an adverse cumulative impact.

- Visual Resources:
  o Large new construction that potentially impacts scenic views or vistas would have an adverse impact.
  o Loss of open space is not assumed to be an adverse impact, but large-scale projects would alter the familiar landscape and are potentially adverse.
  o Development on campuses or military bases would not have a visual impact because base planners have reviewed the plans. The exception is projects that are identified as being on the perimeter of a multi-building development.
  o Landfills, wind turbines and other large infrastructure projects would have adverse visual impacts.
  o Restoration of open space or reforestation would have beneficial impacts.

- Ground Transportation:
  o A project that causes LOS to change from acceptable operating conditions to unacceptable conditions (i.e., from LOS A, B, C, D, or E, to LOS F) would contribute to the adverse impact.
  o The following types of projects contribute to deteriorating LOS: new housing projects; public and institutional facilities such as power plants, health clinics, and schools; hotel and tourism-related structures; and projects in existing congested areas.
  o Road improvement projects would provide a beneficial cumulative effect on traffic LOS.

- Marine Transportation:
  o Projects that repair existing port facilities would have a beneficial impact because it is assumed it would allow the facility to operate more effectively or efficiently thereby increasing capacity.
  o Projects that expand port capacity, directly or indirectly, would have a beneficial impact.
  o More vessels do not equate to an adverse impact. If demand exceeds capacity to accommodate vessels, market forces or government action would respond accordingly.
  o Projects that facilitate an increase in on-island population would have an adverse impact on marine transportation.

- Utilities:
  o New development is subject to GovGuam agency building permit review. Projects would not be approved unless their utility requirements can be met.
  o Recently completed and present projects would have already been approved or conditionally approved. The utility capacity to support the projects was presumably deemed adequate.
  o Recently completed, present, and reasonably foreseeable utility improvement projects would be beneficial impacts.
  o Reasonably foreseeable population inducing plans or programs would have an indirect adverse impact on utility capacity. The Utilities direct and indirect impact analysis on infrastructure capacity addresses population growth and planned DoD projects through 2028; therefore, there may be an overestimate of the potential for cumulative impact on utilities in this chapter.

- Socioeconomics and General Services:
  o A project is considered to have an adverse cumulative effect if: it has the potential to add 2% or more at any point in time to expected population or economic levels; it would cause
substantial increases in staffing, new or physically altered facilities, and/or equipment/vehicles; or it affects public safety or order.
- Projects that preserve or enhance the social fabric would have a beneficial cumulative effect.
- The following types of projects would provide a beneficial cumulative effect: housing projects; public and institutional facilities such as power plants, health clinics, and schools; and hotel and tourism-related structures.

- **Hazardous Materials and Waste:**
  - Hazardous material, hazardous waste and POL storage, use and transport are heavily regulated; therefore, most recent, present of future development projects would not have a significant adverse impact on hazardous material management.
  - Projects that would introduce a new type of material requiring special handling or on Guam would result in a potential adverse impact.
  - New industrial uses or relocation of industrial uses would have an adverse impact.
  - Remedial actions or repair of storage facilities would have a beneficial impact.
  - Demolition projects may generate lead, asbestos or PCB waste resulting in an increase in the quantity of these materials to be managed on island. This would be a potential adverse impact for non-DoD projects. DoD has sufficient demolition waste capacity and regulated; therefore, no impact would result from DoD demolition projects.
  - Projects that characterize potentially contaminated sites would have a beneficial impact because the site would be better managed with this information.
  - Projects that would increase the volume of hazardous material or POL transported to/on Guam or the amount of waste to be managed would have an adverse impact.

- **Public Health and Safety:**
  - Projects that would adversely affect regional traffic, noise, and water quality.
  - Projects that would result in a perception that increasing the military presence on Guam causes the island to be a more likely target for terrorist threat.
  - Projects that would subject the public to increased or decreased risk of contracting a disease or experiencing personal injury.
  - Projects with the potential to increase or decrease the occurrence of notifiable diseases would result resulting in an adverse impact to Guam health care services.
  - The following types of projects provide a beneficial cumulative effect: road, power, sewer, water infrastructure improvements, and hospitals and clinics.

- **Environmental Justice and the Protection of Children:**
  - Non-luxury housing projects and resorts would provide a beneficial cumulative effect for the low-income population by increasing the total supply of housing and creating additional, non-specialized jobs.
  - Projects that improve public services and infrastructure would have a beneficial impact.
  - Renovation/remodeling projects on military bases would not impact environmental justice populations, but growth-inducing mission changes would.

The results of the assessment are presented in Table 7.6-1, which contains the same list of projects that were presented in Table 7.5-1, but the resource column headings have replaced the project description information headings. The total number of projects (i.e., recently completed, present, and reasonably foreseeable) that could contribute to the cumulative effect is tallied and reported in the last rows of Table 7.6-1.
The resources most likely to be adversely affected by projects are terrestrial biology and cultural. This is largely due to the fact that most projects would result in ground disturbance and potential for removal or disturbance of habitat and cultural resources.

The resource areas that benefit most from the projects listed are ground transportation, utilities, socioeconomics and general services, public health and safety and environmental justice. This is because many of the GovGuam projects are capital improvement projects designed to support the health and safety of the community.

A nearly equal number of projects have adverse (marked as X in the Table) and beneficial impacts (shown as B) were identified for geological and soil resources, and water resources. Air quality, noise, airspace land use, recreational resources and marine transportation resource areas are impacted by fewer projects than other resource areas, either beneficially or adversely.

Number of recently completed projects potentially contributing to cumulative effects (X/B): 76

Number of present projects potentially contributing to cumulative effects (X/B): 95

Number of reasonably foreseeable projects potentially contributing to cumulative effects (X/B): 18

Total number of projects contributing to cumulative effects (X/B): 188
7.6.2 Step 6B: Cumulative Impact Analysis of Recently Completed, Present, and Reasonably Foreseeable Future Projects in Conjunction with Collective Action Alternatives

Based on Table 7.6-1, every resource area was or would potentially be impacted by the recently completed, present, and reasonably foreseeable future projects. Table 7.6-2 summarizes the SEIS collective action alternatives (Cantonment/Family Housing + LFTRC + Additive Actions + 2010 ROD-Related Action) impacts from Table 7.4-1. The impacts are simplified to the highest level of significance identified for any criteria under each resource. For example, significant impacts (SI) were identified for geological and soil resources due to the permanent alteration of topography for all alternatives.

The second to the last row of Table 7.6-2 indicates whether the collective action alternatives in combination with the recently completed, present, and reasonably foreseeable future projects could affect the health of the resource or trend associated with the resource. In other words, is there a potential for a cumulative effect? For all resources, if the finding is “yes” there is potential for cumulative effect.

The final row of Table 7.6-2 indicates the magnitude of the cumulative effect (e.g., strong, moderate or low). The magnitude is a function of the current health of the resource, the potential for the resource to sustain its current health if stressed, the geographic extent of the impact, the duration of the impact and a demonstration of cause and effect. The magnitude of the cumulative effect on a specific resource is not necessarily the sum of the effects of all actions, because there may be no cause and effect relationship. For example, a noise level that exceeds the established thresholds for significance in one geographic area would not cause an additive noise impact to a similar noise impact in another geographic area. In contrast, the recovery of a threatened and endangered species could be affected by incremental permanent losses in total available suitable habitat.

The assessment is based on long-term impacts of the proposed action (or collective action) on a resource. The assessment of magnitude is complicated by the consideration of both adverse and beneficial impacts. This is especially true for complex resources with multiple criteria like socioeconomics and environmental justice. The following are general descriptions of strong, moderate and low magnitudes, but the rationale varies with each resource:

- A “Strong” magnitude is applicable to resources where the present and reasonably foreseeable actions plus the collective action alternatives are likely to have an additive significant adverse impact on a resource. These are resources that warrant the establishment of thresholds for their protection or have an island-wide geographic extent. “Strong” is applicable when additive impacts would be impossible to reverse over time, such as the loss of a cultural site.
- A “Moderate” magnitude is assigned when the significant adverse impacts due to the present and reasonably foreseeable actions plus the collective action alternatives are not Guam-wide but could adversely impact a region or community. There may be regulatory thresholds that are exceeded, but they are specific to a location. The long-term impacts could be reversed or mitigated with appropriate resources (i.e., finances, time, expertise). An example is utilities infrastructure where the additive electrical demand could exceed the supply, but infrastructure upgrades would reverse the impact and specific projects have been programmed to eliminate the adverse impact.
- A “Low” magnitude of additive impact is assigned when there is no threshold established for the health of the resource, the threshold is very high or the resource is healthy and resilient to stressors. There is no nexus between the impacts of the proposed action and the impacts of the present and reasonably foreseeable actions. For example, the proposed action may limit public access to GovGuam land and result in a significant direct impact, but present and reasonably
foreseeable projects may not restrict access, so the additive impact among the actions would be low. Generally, the impacts are localized and readily reversible when the project is no longer operational. Impacts on ambient air quality would be considered low, except within a non-attainment area or if the project results in a new non-attainment area.

Table 7.6-2 summarizes the magnitude for each resource and the rationale is presented in the subsequent resource sections under *Potential Cumulative Effects*.
### Table 7.6-2. Potential for Cumulative Effects

|-----------------------------------|---------------------------|----------------|------------|-------|----------|-----------------------------|------------------------|-----------------------------|-----------------------------|-----------------|----------------|-----------------------------|---------------------|-----------------------------|-------------------------------------------------|-----------------|----------------------|---------------------------------|

Does the collective action alternative (SEIS + Additive Actions + 2010 ROD-Related Action) in combination with past, present and reasonably foreseeable projects impact the health of the resource? i.e., is there a potential cumulative effect? Yes [Y] / No [N]

| Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |

What is the magnitude of the additive impact of the collective action in conjunction with past, present, and reasonably foreseeable projects? S - strong; M - moderate; L - low

| L | S | L | L | L | M | S | L | S | L | S | L | M | M | L |

Legend: NI = No impact; LSI = Less than significant impact; SI = Significant impact; SI-M = Significant and mitigable to less than significant. Cantonment/family housing alternatives: A= Finegayan, B= Finegayan and South Finegayan, C = AAFB, D = Barragada. LFTRC alternatives: 1 = Route 15; 2, 3, and 4 = NAVMAG alternatives; 5 = NWF; Blue shading = Preferred Alternative; red font = SI or SI-M.
7.7 **Steps 7 and 8: Report Results and Identify Mitigation**

The primary purpose of this section is to report the results of the various steps of the cumulative effect analysis. The 2010 Final EIS (Volume 7, Chapter 4: Cumulative Effects, Section 4.3.5: Cumulative Effect Assessment, pages 4-33 to 4-87) summarizes the results by resource with the following subsections:

- Current Health and Historical Context (Step 3 results)
- Direct and Indirect Impacts of the Preferred Alternative that might Contribute to a Cumulative Effect (Step 4 results)
- Reasonably Foreseeable Actions that Affect the Resource (Step 5 results)
- Potential Cumulative Effects (Step 6)
- Assess the Need for Mitigation (Step 8)

A similar format is used in this SEIS. However, the current health and historical context (Step 3) is updated with new information and instead of the preferred alternative all collective action alternatives are assessed.

**Mitigation for DoD Projects**

The DoD strives to avoid and minimize impacts during the initial alternatives evaluation and design phase of project development. BMPs, SOPs, and typical permit conditions are also implemented to mitigate impacts. BMPs are a type of mitigation measure but because they are SOPs for the DoD and not project-specific they are considered to be part of the proposed action. Potential project-specific mitigation measures are proposed in this SEIS (Tables 4.7-1 and 5.7-1) and include those resulting from ESA section 7 consultation and cultural resources review. Further, the 2011 PA provides a process for the mitigation of adverse effects to historic properties and impacts to other cultural resources.

The SEIS ROD would identify the mitigation measures that DoD commits to implementing. Mitigation measures can be classified as one of the following two types:

1. **Within DoD control** - DoD has statutory authority to implement actions taking place on lands under its control. DoD has limited statutory authority to implement natural and cultural resources mitigation measures on non-federal land.

2. **Outside of DoD control** - Except for the limited authority applicable to natural and cultural resources identified above, DoD does not have statutory authority to undertake mitigation measures on non-federal land.

Both types of mitigation serve to avoid, minimize, replace, or compensate for impacts if implemented by DoD or non-DoD agencies.

**7.7.1 Geological and Soil Resources**

*Current Health and Historical Context.* As summarized in Sections 3.1, 4.1.1.1, 4.2.1, 5.5.1 of this SEIS and in detail in the 2010 Final EIS (Volume 2, Chapter 3: Geological and Soil Resources, Section 3.1: Affected Environment, pages 3-1 to 3-30), Guam’s geological and soil resources have been most affected by human populations in the past century. Of particular note, are impacts associated with WWII, during which time much of Guam’s foliage was lost to bombings as the U.S. regained control of the island from Japan in 1944.

Subsequent to WWII, soil loss due to erosion is largely attributed to human-induced wildfires; construction and development with inadequate erosion control systems; recreation with off-road vehicles;
and introduced mammals. The occurrence of wildfires has increased over time. Between 1979 and 2001, over 99,000 acres (40,000 ha) of vegetation burned and Guam lost nearly a quarter of its total tree cover. The burn areas are often invaded by non-native grasses or become barren. The replacement of forest with savanna vegetation contributes to elevated soil loss, as erosion in savanna areas may be 100 times higher than in scrub forest. Popular use of off-road vehicles for recreation is also believed to be a major contributor to the development and persistence of erosion-prone cover types.

Construction often requires grading and filling, which may reduce soil quality that, in turn, may affect plant growth and runoff. Topography can be permanently altered in areas of steep slope. Vegetation removal can lead to loss of soils as windborne dust if not properly managed and/or controlled. Compaction also typically occurs at construction sites and can also increase erosion potential. Impervious surfaces (i.e., rooftops, sidewalks, roads, and parking lots) can accelerate water flows and lead to further soil loss and erosion if appropriate stormwater controls are not implemented. These are addressed in the water resource sections. Sinkholes are sensitive to both sediment input from grading activities and changes in hydrology.

Most recently, as in the case of the recently completed and present projects, the more stringent construction permit conditions and BMPs minimize the impact on the geological and soil resources. There is greater awareness of erosion control principles. Although there has been substantial degradation of the resource over time that may not be recoverable; the trend in the decline resource health has slowed. There may be occasional permit violations, but there are also revegetation and ungulate control programs that improve resource resiliency.

There are 21 recently completed projects identified with the potential to contribute to a cumulative effect to geological and soil resources on Guam (see Table 7.6-1), 10 beneficially and 11 adversely. Projects that could contribute to a beneficial impact include GovGuam Route 2 Culverts and Slide Repair (S-1) and Talofofo/Togcha Bridge Rehabilitation (S-2) because the projects may stabilize soils. In contrast, Amusement Park-Tumon (C-12) is a large project that will have a long term adverse impact on topography.

There are 25 present projects identified with the potential to contribute to a cumulative effect to geological and soil resources on Guam (see Table 7.6-1), 16 of which have a beneficial impact on this resource. Two beneficial projects are Agfayan Bridge Replacement (S-19) and Reforestation of Masso Reservoir (AH-2). Emerald Ocean View Park (C-21) would have long-term impact adverse impact on topography.

**Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect.** As summarized in Tables 7.4-1 and 7.6-2 a significant impact on this resource would result under each of the collective action alternatives, except A-2, B-2, C-2, D-2, and E-2 that would have a less than significant impact. This significant impact is due to the long-term adverse topographic impacts associated with the grading required to develop the LFTRCs and the 2010 ROD-Related Actions. Less than significant impacts were identified for impacts on soils, sinkholes and geologic hazards for each of the collective action alternatives with the implementation of BMPs.

**Reasonably Foreseeable Actions that Affect Geological and Soil Resources.** There are two reasonably foreseeable projects identified with the potential to adversely impact topography including Sigua Highlands (C-47). Eight potentially beneficial projects include roadway improvement projects because they could reduce erosion associated with degraded pavement, such as Asan and Aguada Bridge Rehabilitation (AH-9).
Potential Cumulative Effects. Anticipated long-term impacts associated with collective action operations would not have an adverse cumulative effect when combined with the recently completed, present, and reasonably foreseeable actions on Guam identified above. Moreover, several activities and projects would have a beneficial impact on geology and soil resources both now and in the future. Uncontrolled human uses and natural events (e.g., typhoons, tropical storms, earthquakes, tsunamis) would continue to have an adverse impact on geological and soil resources. The significant impact identified for the collective action alternatives was related to topography. There are no thresholds established for the acceptable level for changes in topography. The magnitude of additive impact resulting from the collective action alternatives and recently completed, present, and reasonably foreseeable actions is considered to be low and would not appreciably impact the resiliency of geological resources on Guam over time (see Table 7.6-2).

Need for Mitigation. Potential mitigation measures proposed for avoiding or reducing impacts to resources are listed in Tables 4.7-1 and 5.7-1. No additional mitigation measures for cumulative effects are proposed.

7.7.2 Water Resources

Current Health and Historical Context. The historical context of surface water, groundwater, nearshore water, and wetlands on Guam is summarized in Sections 3.2, 4.2.2, 5.5.2, and in the 2010 Final EIS (Volume 7, Chapter 4: Cumulative Effects, Section 4.3.5.1: Guam Cumulative Effects Assessment, page 4-33). Soil erosion and stormwater runoff are largely responsible for degradation of surface and nearshore waters. As described above under Geological and Soil Resources, the introductions and increases of domesticated animals (water buffalo, pigs, goats, and deer) and farm crops likely denuded soils and contributed to erosion from vegetation loss and trampling. During WWII, much of Guam’s foliage was lost to bombings. When the U.S. retook control of the island from Japan in 1944, tangantangan (native to the Americas) was planted to control erosion.

As described under Section 7.7.1, Geological and Soil Resources, wildfires and off-road vehicles contribute to soil erosion. The result is increased sedimentation/siltation of surface water. Eroded silt from these burn areas also destroys marine life in reefs around the island. In addition the loading of sediments in freshwater streams increases the turbidity in sources of drinking water, which can reduce the performance of treatment processes such as chlorine disinfection.

Once construction is complete, the addition of impervious surfaces (i.e., rooftops, sidewalks, roads, and parking lots) can accelerate water flows and lead to further soil loss and erosion if appropriate stormwater controls are not implemented. Past construction and development on Guam has resulted in the addition of approximately 12,280 acres (4,970 ha) of developed impervious surface area, representing approximately 1% of the island’s total land area; there remains sufficient pervious surfaces for groundwater recharge.

Threats to surface water would continue to be monitored by federal and Guam agencies, and appropriate regulatory action would continue to occur to maximize surface water quality and availability. In time, with the implementation of stormwater BMPs during construction and operation, surface water resource impacts due to new projects would slow the decline of water quality. Monitoring and enforcement of permit conditions may be limited due to lack of funding but there is an increase in public awareness of the effects of erosion on water quality that could lead to greater reporting of permit violations. This would not correct the historical adverse impacts but could result in less of an impact due to future projects.

The nearshore water quality concerns for the marine waters of Guam include copper, aluminum, nickel, enterococci bacteria, total residual chlorine, biochemical oxygen demand, and total suspended solids. The non-point sources of these water quality concerns are difficult to address, but the planned improvements
to wastewater infrastructure, required upgrades of WWTPs treatment systems (as required by current NPDES permits), and the implementation of BMPs to address stormwater are expected to slow down the degradation of nearshore water quality due to man-made activities.

Threats to groundwater availability and quality (e.g., saltwater intrusion, leaky septic systems, and sewage spills) would continue to exist. A recently developed numerical groundwater model and an updated and expanded network of wells to monitor groundwater level and water quality would be used by the GWRDG to manage the NGLA. The improved management and monitoring of the NGLA and fewer septic systems in use (as anticipated in the future) are expected to ensure that a dependable and safe supply of groundwater would be maintained for Guam. In time, groundwater quality would be expected to slowly improve on Guam as point and non-point sources of pollution are identified, and pollution loading to surface waters is reduced, all within the framework of improved management and monitoring of the NGLA. In addition, the mission of the GWRDG (including DoD, GWA, GEPA, Consolidated Commission on Utilities, GDPW, and WERI) is to protect Guam’s water supply for quantity, quality, reliability, sustainability, and availability for all of Guam - present and future.

Wetlands are impacted by soil erosion and physical removal and wetlands have been reduced or compromised overtime. These threats to wetland areas are monitored by federal and Guam agencies. Appropriate regulatory action would continue to occur to protect wetland areas. While the federal regulation focuses on a principle of no overall net loss to wetlands, there has been a historical loss of wetlands prior to regulatory control that would not be remedied. The non-point sources of pollution on Guam are not fully characterized and would continue to adversely impact wetlands. The implementation of BMPs described above for erosion control would reduce the rate at which wetlands degrade. In the future, it is anticipated that surface water, groundwater, nearshore and wetland quality would continue to decline, but the regulatory controls are expected to slow the rate of decline.

Fifty-two recently completed projects with the potential to contribute to a cumulative effect to water resources on Guam were identified (see Table 7.6-1). Nineteen of the projects would have a beneficial impact on water resources such as: Masso River Bridge Embankment (AH-3) and Togcha Bridge Rehabilitation (S-2), because they would potentially reduce erosion in surface waters. The new Dandan Landfill project (S-3) is heavily regulated and routinely monitored and stabilizes the badlands at the site. The adverse impacts associated with the projects are due to the increase in impervious surface and potential to impact stormwater. These varied projects include the Amusement Park (C-12) and residential development such as Hemlani Apartments (C-34). There is insufficient information on the projects to describe potential impacts to wetlands.

Ninety-six present projects with the potential to contribute to a cumulative effect on water resources on Guam were identified (see Table 7.6-1). Forty projects are potentially beneficial to water resources, because they are utility improvements or roadway improvements or rehabilitation projects that would likely minimize long-term sedimentation of surface water. These projects include: Deep Well Rehabilitation (G-17), Rehabilitation of Asan Springs (C-30), Reforestation of Masso Reservoir (AH-2), Hagåtña Sewage Treatment Plant (STP) Improvements (C-42), Northern District WWTP Phases 1-3 (N-32) and WWTP Priority 1 Upgrades (G-21). The new construction projects that would increase the amount of impervious surface could have an adverse impact, the largest of which include: Emerald Ocean View Park (C-21), and Sigua Highlands / near Leopalace (C-47). There is insufficient information on the projects to describe potential impacts to wetlands.
Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect. As summarized in Tables 7.4-1 and 7.6-2 less than significant impacts to surface waters are anticipated for the NAVMAG LFTRC alternatives and no impact was identified for the others.

Short-term, localized significant-mitigable impacts to the affected basin within the NGLA but less than significant impacts to the overall NGLA were identified for all collective action alternatives due to long-term increase in annual groundwater production of 1.7 MGd (6.4 MLd) from the NGLA. This impact is the same for all collective action alternatives. This assessment assumes BMPs are effective at controlling soil erosion, pollutants of concern, and stormwater flow. The collective action alternatives would increase the impervious surface on Guam by approximately 176 acres (71 ha) for the cantonment/housing and LFTRC alone, representing an increase of approximately 1.4% of total development-related impervious surface area on the island. The 2010 ROD-Related Actions would result in additional impervious surface. Increases in impervious area would be managed through the implementation of an appropriate and comprehensive stormwater management plan utilizing a LID approach as described in Section 4.1.2.2 of this SEIS.

Groundwater production rates would slightly increase, and the implementation of sustainability practices would reduce the amount of groundwater needed per capita, which would help minimize impacts to groundwater availability. The resulting total annual groundwater production would be substantially less than the sustainable yield. Improved management and monitoring of the NGLA aquifer by the GWA and DoD would ensure increased pumping does not adversely affect sources of drinking water on Guam.

Significant and mitigable impacts were identified for all cantonment alternatives due to potential increases in the rate of sewage spills associated with the induced civilian growth and construction/DoD workforce would result in significant indirect impacts to groundwater quality. A potential mitigation measures includes DoD assisting GovGuam in identifying funding to upgrade the sewer lines.

Significant and mitigable impacts were identified for all cantonment alternatives due to an increase in wastewater discharge from the Northern District WWTP and for Alternative D also having an increase in wastewater discharge from the Agaña WWTP, which are both currently non-compliant with their current NPDES permits. Potential mitigation measures includes DoD assisting GovGuam in upgrading the Northern District WWTP treatment systems (as required by current NPDES permits) and in identifying additional sources of funding to construct treatment facility improvements at the Agaña WWTP. Once the WWTPs are in compliance, the long-term nearshore water quality is expected to improve.

Significant mitigating impact on wetlands would result with the three collective action alternatives that propose LFTRCs at NAVMAG. Specifically, the alternatives are: A-2, A-3, A-4; B-2, B-3, B-4; C-2, C-3, C-4; D-2, D-3, D-4; and E-2, E-3, E-4. In addition, the cantonment alternative at Barrigada could have a long-term indirect impact to approximately 0.1 acre (0.04 ha) of wetlands. The wetland impacts at NAVMAG range from 17.7 acres (7 ha) for the East/West LFTRC to 36.9 acres (15 ha) for the North/South LFTRC. No wetlands were identified for the 2010 ROD-Related Actions and the additive impacts of Section 6.1. The collective action alternatives that include Barrigada for cantonment and NAVMAG for LFTRC (i.e., D-2, D-3, D-4) would have a slightly greater impact on wetlands than the other collective action alternatives. Potential mitigation measures would be developed during the Section 404 permit application review.

Reasonably Foreseeable Actions that Affect Water Resources. Fifteen reasonably foreseeable projects are anticipated to contribute to a cumulative effect on water resources on Guam (see Table 7.6-1). Ten of the projects are presumably beneficial because they are roadway rehabilitation projects that improve pavement integrity resulting in less erosion potential, such as: Route 10A, Rehabilitation & Widening.
Sunset Blvd. to Route 16 (C-37), Asan and Aguada Bridge Rehabilitation (AH-9). The remaining projects include development of various sizes throughout the island that would contribute to an increase in impervious surface, such as Guam Regional Medical City (N-38). Additionally, development projects are likely to increase the demand on Guam’s groundwater resources, particularly the NGLA.

**Potential Cumulative Effects.** Recently completed, present, and reasonably foreseeable future projects would involve construction activities that would result in the potential for a temporary increase in stormwater runoff, erosion, and sedimentation. For projects disturbing more than 1 acre (0.4 ha) during construction (including the collective action alternatives), a Construction General Permit would be obtained and followed, and a SWPPP would be prepared and implemented to minimize temporary increases in runoff and pollutant loading related to construction activities. There is an existing DPRI Construction Program final Comprehensive SWPPP for the 2010 ROD-Related Actions that are included in the collective action impacts.

In addition, recently completed, present, and reasonably foreseeable future projects would result in an increase in impervious surface area in urban and industrial settings, resulting in a corresponding increase in stormwater runoff that has the potential to have elevated levels of contaminants, such as sediments, nutrients, heavy metals, organic and inorganic compounds, and detrimental microorganisms in water resources. Many of these projects especially, if they are new construction, are likely to increase the impervious surfaces that would result in an associated increase in stormwater discharge intensities and volume. New projects are subject to GovGuam review which includes a review of drainage and stormwater control.

In addition, cumulative actions would be expected to increase the amount of POLs, hazardous waste, pesticides, and fertilizers being stored, transported, and utilized. Increasing the storage, transportation, and use of these substances would increase the potential for releases to water resources. Implementation of BMPs associated with addressing site- and activity-specific water resource protection needs, provisions of facility-specific SWPPPs, and SPCC Plans would minimize potential impacts from facility operations, to include the transportation, storage, and use of fuel, on all water resources. In addition, adherence to surface water quality and volume control measures would also reduce pollutant loading to groundwater basins, nearshore waters, and wetlands. Many of the projects could potentially impact water resources. The cantonment/family housing and LFTRC would increase the total existing development-related impervious surface area on Guam by approximately 1.4%; however, the implementation of BMPs and LID measures would ensure no off-site transport of excess stormwater runoff. The additive effect of the collective action in conjunction with the cumulative actions is expected to be low.

Recently completed, present, and reasonably foreseeable future projects include connections to wastewater collection, treatment, and disposal systems. Short-term, direct impacts from increased wastewater discharge from the Northern District WWTP would be non-compliant with the 2013 NPDES permit that requires treatment system upgrades. There are a large number of projects, including other DoD projects, in the northern part of Guam. Four of the five cantonment alternatives also are proposed in the northern part of Guam. There is potential for a strong cumulative impact on nearshore water quality associated with increased service loads at the Northern District WWTP, which is not in compliance with NPDES permit requirements. Once upgrades to address the permit conditions have been completed there would be an improvement to nearshore water quality. This cumulative effect to nearshore water is not expected for other geographic areas of Guam.

Projects that would reduce and/or ensure less reliance on septic systems for wastewater disposal; thereby resulting in a benefit to groundwater resources. Furthermore, identified sustainability measures associated
with the collective action alternatives (e.g., conserving water), when combined with similar measures for applicable cumulative actions, would benefit groundwater resources. These measures would also benefit nearshore waters by reducing the nutrient and bacteria load. The collective action would not have a cumulative effect on these beneficial impacts, except as described for the Northern District WWTP improvements as described in the previous paragraph.

Average daily groundwater production rates are estimated to increase due to the collective action by 1.7 MGD (6.4 MLD). In addition to potable water demand generated under Alternative A, organic civilian population growth independent of the proposed action is estimated to result in an average daily long-term increase in water demand of 3.5 MGD (13.2 MLD). The demand from organic civilian growth would be satisfied by the GWA system, primarily from the NGLA, but also from surface water in southern Guam. The forecast water demand increases steadily through year 2028 due to the impact of induced and organic civilian growth. Total average daily water extraction from the NGLA from all sources (DoD water system, GWA water system, and a few private wells) is estimated to be 47.0 MGD (177.9 MLD) in year 2028 but would be less than the sustainable yield of 80.5 MGD (304.7 MLD). Management of the NGLA would be improved through the use of the numerical groundwater model and an updated and expanded network of monitoring wells. The magnitude of the additive cumulative effect of the collective action on ground water in conjunction with the cumulative actions is strong.

2010 ROD-Related Actions and non-DoD projects involving construction in Apra Harbor would have the potential for cumulative effects to nearshore waters. However, these projects would require Section 404(b) and Section 10 of the Rivers and Harbors Act permits from the USACE, and Water Quality Certification from the GEPA. Permit conditions mitigate the impacts on surface water. The additive effect would be low in magnitude.

There is the potential for the recently completed, present, and reasonably foreseeable future projects to have direct and indirect impacts to wetland areas possibly resulting in the loss of wetland area and/or function. The collective action alternatives that include NAVMAG LFTRCs would impact wetlands. Per USACE regulations, activities that are proposed in wetlands or that could potentially reduce wetland area or function must be permitted and potentially mitigated to compensate for impacts to wetland areas. Therefore, any loss of wetland area or functionality would be potentially mitigated at a project and site-specific ratio, which would likely include creating or enhancing existing wetland habitat elsewhere on Guam. Indirect impacts to wetland areas (e.g., runoff, sediment loading) would be addressed on a project-specific level, and would likely be lessened with BMPs and associated short- and long-term stormwater runoff management measures. There is insufficient information on the recently completed, present, and reasonably foreseeable future projects to assess the potential for cumulative effect on wetlands; however, the assumption is GovGuam agencies would not approve projects that have a direct impact on wetlands. While the collective action may have a significant mitigable impact on wetlands, the additive effect is considered low in magnitude.

In summary, implementation of the collective action alternatives, when considered in conjunction with specific projects on Guam, would have a cumulative effect on water resources. The additive effect of each collective action alternative would be strong (see Table 7.6-2) specifically as it relates to the nearshore waters of northern Guam and the Northern District WWTP and groundwater.

Need for Mitigation. Potential mitigation measures proposed for avoiding or reducing impacts to resources are listed in Tables 4.7-1 and 5.7-1. GovGuam reviews private and commercial development proposals for potential impacts to water resources. There are ongoing local and federal conservation and
restoration efforts to improve water quality. No additional mitigation measures for cumulative effects are proposed.

### 7.7.3 Air Quality

**Current Health and Historical Context.** Guam’s air quality is described in detail in the 2010 Final EIS (Volume 2, Chapter 5: Air Quality, Section 5.1: Affected Environment, pages 5-1 to 5-14). There are no comprehensive ambient background air quality levels from recent monitoring available for Guam. Guam’s existing background air quality conditions can be defined based on the current ambient air quality attainment status applicable to Guam, which is:

- Attainment for all criteria pollutants except SO$_2$.
- Two SO$_2$ nonattainment areas within a 2.1-mile (3.5-km) radius around Piti and Tanguisson power plants.

Except for power generating facilities, there are no significant stationary sources of air emissions on Guam. It can be assumed that prior to the non-attainment designation in the 1970s; historical ambient air quality was good before and after WWII.

Four recently completed projects were identified with the potential to contribute to a cumulative effect to air quality (see Table 7.6-1). Three projects with potential adverse impacts, including Route 8/10/16 Tri-intersection (C-16), could contribute to the exhaust from idling vehicles. The Ungulate Fencing project (N-24) is likely to have a beneficial impact by promoting the growth of more vegetation to absorb air quality particles.

Eight present projects with the potential to contribute to a cumulative effect to air quality on Guam were identified (see Table 7.6-1). The wind turbines (C-32) are expected to have a beneficial impact by offsetting the increased use of fossil fuels for power generation, while the Pacific Airpower Resiliency (N-26) is likely to have an adverse impact due to an increase in air traffic and use of fossil fuels.

**Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect.** The collective action alternatives would result in less than significant and mitigable impacts to Guam’s air quality, as summarized in Table 7.4-1 and 7.6-2. Operational air emissions originate from stationary and mobile sources. The basis of the air impact analysis was a significance criterion of 250 tons per year for air pollutants. Air emissions associated with both construction and operation of the collective action alternatives would be well below the significance criteria of 250 tons per year for all air pollutants. It is the on and off-base vehicle traffic that could exceed the 250 tons per year threshold of significance for CO. These impacts, however, would be temporary and localized at intersections. Construction and operational phase off-base roadway hot spot particulate matter, carbon monoxide, and mobile source air toxics impact conclusion will be provided after the analysis is completed. The cantonment/family housing and LFTRC pairings, the additive impacts of Section 6.1 and 2010 ROD-Related Actions would all contribute to the less than significant impacts of the collective action alternatives.

**Reasonably Foreseeable Actions that Affect Air Quality.** One reasonably foreseeable project is anticipated to contribute to a cumulative effect to air quality on Guam (see Table 7.6-1). The 60 MW Power Plant (G-6) is the project likely to have an adverse impact because of increased fossil fuel use and expanded flight capacity.

The future traffic growth would likely result in an increase in mobile source emissions on Guam. However, the reduction of mobile source engine emissions in the future, per CAA requirements, would contribute to a reduction of the overall mobile source and greenhouse gas emissions. Therefore, the air
quality conditions affected by mobile source operations would likely remain the same or improve slightly, as compared to the existing conditions.

**Potential Cumulative Effects.** Current projects on Guam consist primarily of building developments, infrastructure upgrades and improvements, and military projects that would contribute to man-made air emissions. Activities that increase emissions in the non-attainment areas are likely to have a greater cumulative effect. However, there are projects that are expected to reduce air emissions, such as the port improvements. The GEPA has adopted the USEPA-established stationary source regulations discussed previously, and acts as the administrator to enforce stationary source air pollution control regulations on Guam. Current air quality regulations are applied to air emissions from new sources for the protection of human health. The recently completed, present, and reasonably foreseeable future projects would not necessarily result in increases in island-wide traffic and air emissions, but new destinations would shift the emissions from mobile sources.

There will be cumulative effects associated with the collective action alternatives and the actions of other federal agencies, local governments, and the private sector on air quality on Guam. The degree of additive impact resulting from the collective action alternatives is considered to be low, in part because the collective action alternatives are not located in the non-attainment area and would not exceed air quality thresholds. The cumulative effect would not appreciably impact the quality of the ambient air over time (see Table 7.6-2).

**Need for Mitigation.** Potential mitigation measures proposed for avoiding or reducing impacts to resources are listed in Tables 4.7-1 and 5.7-1. No additional mitigation measures for cumulative effects are proposed.

### 7.7.4 Noise

**Current Health and Historical Context.** Guam’s noise environment is discussed in detail in the 2010 Final EIS (Volume 2, Chapter 6: Noise, Section 6.1: Affected Environment, pages 6-1 to 6-20). WWII bombings and air operations may represent the loudest period on Guam’s history; however, those noise impacts were not long-term. Existing sources that contribute to ambient noise include the commercial airport, AAFB airfield, industrial facilities, military training range activities, and traffic. Most of these noise impacts are intermittent. Industrial noise, such as power generation, would emit noise for longer periods, but is subject to OSHA regulations to protect the hearing of sensitive receptors, specifically workers. There is no island-wide noise level monitoring, and trends in noise are not documented island-wide. The cumulative effects would be geographically limited.

Two recently completed actions with the potential to contribute to cumulative effects on noise on Guam were identified (see Table 7.6-1): MIRC (G-2) and Naval Hospital Replacement (C-8), both of which would involve air traffic that generates noise. They are not in the same geographic location.

Four present projects with the potential to contribute to a cumulative effect to ambient noise on Guam are located at AAFB, including the PRTC RH Airfield Operations (N-49).

**Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect.** As summarized in Tables 7.4-1 and 7.6-2, there would be a significant mitigable impact on ambient noise due to the LFTRC at Route 15 that is a component of the following collective action alternatives: A-1, B-1, C-1, D-1, and E-1. Civilian residences were identified within the Zone 2 noise contour. Potential mitigation measures are summarized in Table 5.7-1. All other collective action alternatives would have a less than significant impact on noise due to cantonment traffic, 2010 ROD-Related Actions (i.e., airfield operations).
Reasonably Foreseeable Actions that Affect Noise. One reasonably foreseeable future project involving air operations that is anticipated to contribute an adverse noise impact on Guam (see Table 7.6-1) is Guam Airport Projects (C-35). The adverse impact is based on presumption that the improvements could facilitate more air traffic-related noise.

Potential Cumulative Effects. Operations of all the recently completed, present, and reasonably foreseeable future projects would generate some level of noise, but none are likely to exceed federal or local noise level thresholds for compatible land uses beyond the property boundary. Military mission changes, changes to commercial air traffic and increases in roadway traffic would likely have the most impact on ambient noise levels. Cumulative effects would result when these localized impacts overlap and impact the same sensitive receptors.

The significant mitigable noise impacts associated with the LFTRC at Route 15 would be in the vicinity of Guam International Raceway, which also generates noise. There would be no cumulative effect because the collective action alternative precludes the operation of the raceway. Besides traffic and quarry operations (N-17), no other significant noise generators were identified in the vicinity that could contribute to a cumulative effect. Cumulative noise effects were not identified in the geographic area of the NAVMAG LFTRCs.

The air combat element of the 2010 ROD-Related Action would contribute to the noise generated from other recently completed, present, and reasonably foreseeable actions at the AAFB airfield. However, no additive impact was identified on the civilian community outside of the installation. The existing noise contour that encumbers the community would not expand.

There would be noise impacts associated with the NWF LFTRC collective action alternatives and there are ongoing training activities at NWF that contribute to the noise levels in the vicinity. However, no additive impact was identified on the private residences outside of AAFB. An additive noise impact on terrestrial biological resources was identified, as described in Section 7.7.8.

There would be impacts associated with the collective action alternatives and the actions of other federal agencies, local governments, and the private sector on ambient noise on Guam; however, the effects would not be concentrated in one geographic area. The collective action alternatives would have a low additive cumulative effect, because the affected areas are geographically limited and the impacts are reversible when operations cease (see Table 7.6-2).

Need for Mitigation. Potential mitigation measures proposed for avoiding or reducing impacts to resources are listed in Tables 4.7-1 and 5.7-1. No additional mitigation measures for cumulative effects are proposed.

7.7.5 Airspace

Current Health and Historical Context. As summarized in Sections 3.5, 4.2.5, 5.5.5, and in the 2010 Final EIS (Volume 7, Chapter 4: Cumulative Effects, Section 4.3.5.1: Guam Cumulative Effects Assessment, page 4-40), SUA is designed to alert users about areas of military activity, unusual flight hazards, or national security needs, and to segregate that activity from other airspace users to enhance safety. The commercial air traffic fluctuates based on tourism levels, and military use at AAFB is mission-dependent. Training activities are addressed in the MIRC Airspace Environmental Assessment/Overseas Environmental Assessment and MITT EIS/OEIS (discussed in Section 7.5). Construction activities rarely impact airspace, but airspace may be impacted by operations on the ground. Because there are multiple, and sometimes competing, demands, the FAA considers all aviation airspace requirements in relation to airport operations, federal airways, jet routes, military flight training activities, and other special needs to
determine how the National Airspace System can best be structured to satisfy all user requirements. Significant impacts are avoided prior to FAA approval. While there is a trend toward an increase in air traffic or ground-based activity that may potentially impact air navigation, significant impacts are avoided through regulatory oversight. Since the 2010 Final EIS, there have been no substantive changes to the quantity and quality of airspace Guam-wide and there have been no substantive changes to laws, regulations or policies relative to airspace.

There are two recently completed projects that have the potential to contribute to a cumulative effect to airspace on Guam: Naval Hospital Replacement (C-8), because there is a helicopter landing site and Air Freight Terminal Complex (N-23), because it could represent an increase in air traffic (see Table 7.6-1). However, the existing SUAs described in the affected environment sections of this SEIS represent the cumulative effects on airspace to date.

Eight present projects have potential to contribute to a cumulative effect. Two of these are wind turbine projects (S-4 and C-32) that would likely be subject to FAA approval prior to construction, if they were to occur near a runway, to ensure there was no air navigation hazard. No cumulative effect would be associated with these projects. Pacific Air Power Resiliency (N-26), MIRC Airspace (G-3), MITT (G-23) and Terminal High Altitude Area Defense (N-39) would impact military air traffic. As these projects are reviewed by FAA, they are incorporated into the airspace existing condition.

Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect. All of the collective action alternatives have potential to result in a significant mitigable direct impact on airspace. The impact on commercial air traffic is distinct from military air traffic. Significant mitigable impacts on civilian air traffic were identified for collective action alternatives, except those that included NWF LFTRC (see Tables 7.4-1 and 7.6-2). The NWF LFTRC collective action alternatives (i.e., A-5, B-5, C-5, D-5, and E-5) would have a less than significant impact on civilian air traffic because they would be located a greater distance from the Guam International Airport airspace. These collective action alternatives affecting NWF would have a significant mitigable impact on military air traffic, while the other alternatives would have no impact on military air traffic.

The cantonment/family housing component of the collective action alternative would have would have no impact on airspace. There would be an increase in the total aircraft under the 2010 ROD-Related Actions, but the existing SUA would be used.

Reasonably Foreseeable Actions that Affect Airspace. There is one reasonably foreseeable project that could potentially contribute to a cumulative airspace impact on Guam, Guam Airport Project (C-35), because airport improvements could increase the air traffic capability or require changes to airspace (see Table 7.6-1).

Potential Cumulative Effects. FAA manages the cumulative effect of air traffic and SUA to ensure there are no significant impacts to airspace. There is a potential additive impact between the collective action alternatives and the recently completed, present, and reasonably foreseeable future projects, resulting in modifications to and additional SUAs over time. The degree of additive adverse impact on air traffic resulting from the collective action alternatives is considered to be low, primarily due to FAA regulatory control (see Table 7.6-2). The effects would be reversible if air traffic is reduced and live-fire training stopped.

Need for Mitigation. As summarized in Table 7.6-2, the military and civilian air traffic significant impacts would be further studied through the DON/FAA consultation process and measures would be identified through this consultation process to minimize the potential impacts associated with the proposed action.
The FAA consultation process is applicable to recently completed, present and future projects. No additional mitigation is warranted.

### 7.7.6 Land and Submerged Land Use

**Current Health and Historical Context.** In the 1950s, Guam land use zoning was adopted to manage non-federally controlled land development. Submerged lands ownership has not changed substantially since 1975. As lands were released through BRAC, adjacent submerged lands were not released. There have and will continue to be zoning variances, conditional use permits, and changes to the zoning map. Historically, these were granted excessively, without consistent long range planning. The recent past, current and future trend is for increased management of land use to be consistent with community and master plans; however, it is difficult to correct historical zoning decisions. The development that is inconsistent with zoning is occurring at a less rapid rate. Public access restrictions to federal land and submerged lands have historically been and continue to be a land use issue. The amount of federal land has decreased substantially since WWII.

Access to fishing areas and other recreational areas has declined over time due to designated military training areas and the GovGuam designation of Marine Protected Areas, as shown on Figure 3.6.1-1. The restricted areas are spread out along Guam’s coast and offshore waters. The training events and tempo are not continuous and notice to mariners is provided in advance of the training event. The prime fishing areas are not contiguous. Favorable ocean conditions suitable for fishing or other recreation activities are not constant or predictable and also contribute to submerged lands inaccessibility. There are some areas such as the northern and eastern submerged lands that tend to be rough water most of the year, which increases the demand for submerged land access to western and southern submerged lands. Homeland Security guidelines include maintaining a minimum of 100-yards (91 m) distance from and maintaining minimal speed within 500 yards (457 m) of a U.S. naval vessel. The recreational vessels must detour around naval traffic. All of these factors contribute to the cumulative limitations of public access to prime fishing/recreational submerged land areas.

There are fish aggregating devices and shallow water moorings that facilitate access to submerged lands for recreational use; however, they require maintenance pending available funding and some are no longer useable. Access to the offshore fishing areas on the eastern and northern Guam coast is limited by minimal wharf/pier infrastructure and generally unfavorable ocean conditions. Although there are no regulatory thresholds for measuring these types of land use impacts, the public access to submerged lands is likely to continue to be constrained by natural and anthropogenic factors.

Six recently completed projects with the potential to contribute to a cumulative effect to land and submerged land use on Guam were identified (see Table 7.6-1) and two of these could be beneficial, including Upgrade of Existing 14 Megavolt Ampere Power Transformer to 30 Megavolt Ampere and Underground Line (G-5) and Release a Guam Land Use Plan 77 Parcel Near South Finegayan (N-15). The former minimizes land use restrictions by undergrounding a utility line and the latter reduces federal land. Large development projects have potential to adversely impact adjacent land uses, including Amusement Park-Tumon (C-12). The MIRC EIS (G-2) proposed increases in training tempos on various ranges on and around Guam that potentially adversely impact public access to submerged lands.

Nine present projects with the potential to contribute to a cumulative effect to land and submerged land use on Guam were identified (see Table 7.6-2) and five are potentially adverse, including UOG Wind Turbine (C-32); 15 MW GovGuam Solar/Wind Turbine (S-4); Guam Regional Medical City (N-38) and MITT (G-23). Wind turbines and large medical facilities may have land use siting/compatibility issues. Lateral Conversion of Power Lines to Underground Lines (G-11) could have a beneficial impact on land...
Use. MITT would have an adverse impact on submerged land public access to recreational activities, including fishing.

Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect. All collective action alternatives would result in significant impacts to land or submerged land use, except collective action alternatives involving the NAVMAG North/South LFTRC (i.e., A-3, B-3, C-3 and D-3), which were described as having less than significant impacts on land use. The significant impacts are due to new or an increased level of restrictions on public access to areas that are important to the community. Primarily, the impact is related to LFTRC land acquisition and the encumbrance of submerged lands by the SDZs, both of which restrict public access.

The collective action alternatives that include the Route 15 LFTRC (i.e., A-1, B-1, C-1, D-1, and E-1) have additional impacts associated with incompatibility with existing and future residential land uses that contribute to the significant impact, such as the closure of Guam International Raceway and residential uses within the noise Zone 2 and 3 contours.

The NAVMAG East/West and NAVMAG L-Shaped LFTRC (Alternative 2 and 4, respectively) would potentially impact the use of the Bolanos Conservation Area.

The 2010 ROD-Related Actions (Section 6.2) and the additive impacts (Section 6.1) do not contribute to the level of land/submerged land impacts.

Reasonably Foreseeable Actions that Affect Land and Submerged Land Use. Two reasonably foreseeable future projects are anticipated to contribute to a cumulative effect to land and submerged land use on Guam (see Table 7.6-1). For example, GovGuam proposes a prison (G-10) and a new 60 MW power plant (G-6) that may have siting/land use compatibility issues.

Potential Cumulative Effects. The military training projects would continue to the current level of or increase the public access restriction to submerged lands during training events. The proposed collective action alternatives with LFTRC SDZs that extend into submerged lands, including the preferred alternative, would have a significant impact on submerged land use. GovGuam review of projects would ensure that the non-DoD projects are compatible with existing and future land uses.

Public access to submerged lands for fishing and other recreational activities has declined over time due to a variety of natural and anthropogenic factors. The additive impact of the proposed collective action alternatives (those with LFTRC SDZs in submerged lands) in conjunction with the declining “health” of submerged land public access would result in a cumulative moderate magnitude of adverse impact. The impact is reversible with changes in military training tempo and decreased submerged land regulation; however, there are no plans to reduce these restrictions. There will always be uncontrollable natural conditions such as stormwater runoff and unfavorable weather that would also contribute to reduced public access to submerged lands.

Need for Mitigation. DoD would work with GDAWR and the GFCA in their ongoing efforts to install and maintain fish aggregating devices and shallow water moorings to improve submerged land access for private and military use. Other potential mitigation measures proposed for avoiding or reducing impacts to resources are listed in Tables 4.7-1 and 5.7-1.

7.7.7 Recreational Resources

Current Health and Historical Context. Sections 3.7, 4.2.7, 5.5.7, and in detail in the 2010 Final EIS (Volumes 2, 4, and 5, Section 9.2; Volume 6, Section 11.2), summarize the historical context of recreational resource uses. The boom in the tourist industry in the early 1990s likely resulted in an
increase in conflicts among recreational users and physical deterioration of resources. Other human and natural factors, such as typhoons, coral bleaching, illegal harvesting of coral and fish, non-point source pollution, and insufficient funding for resource management, would continue to adversely impact recreational resources.

Nine recently completed projects with the potential to contribute to a cumulative effect to recreational resources on Guam were identified (see Table 7.6-1). Seven projects could add to the potential number of recreational users and thus have the potential to adversely impact, including Workforce Housing (N-10) and a new hotel (C-4), Talo Verde Estates (C-2), and Hemlani Apartments (C-34). Two projects could have a beneficial impact because they add diversity and/or create recreational opportunities. This includes the recent completion of the Amusement Park in Tumon by Tagada Guam (C-12) and the new GovGuam Student Center (C-13).

Sixteen present projects have the potential to contribute to a cumulative effect to recreational resources on Guam (see Table 7.6-1). Five projects could have a beneficial impact to recreational resources by adding to the diversity and quantity of options for recreation, such as swimming pools, tennis, and/or golf. Gregorio D. Perez Marina Renovation & Site Improvement Project (C-39) and Gregorio D. Perez Marina Dock C Repairs (C-40) would improve the marinas used by recreational boaters. However, the majority of projects could adversely impact recreational resources because they could increase the resident population. Projects that increase housing and accommodations (C-21), and new residential style housing (N-36) could create more individuals seeking leisure and recreational activities.

**Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect.** As summarized in Tables 7.4-1 and 7.6-2, the impact on recreational resources would be significant for all of the collective action alternatives. Within the vicinity of the proposed NWF LFTRC (Alternative 5), there are a number of recreational opportunities, including beaches, picnic sites, camping areas, water sport sites, fishing and game sports, nature activities, scenic drives and overlooks, interpretive centers and parks, particularly the Guam NWR. The SDZs for the LFTRC extend over many of the aforementioned ocean and shoreline recreational resources. Operations would impact 147 acres (57 ha) of the Ritidian Point Unit of the Guam NWR and 240 acres (97 ha) of beachfront may be restricted during training exercises as described in Section 5.5.7.2. Access to much of this area is already restricted for natural resources conservation purposes.

The Guam International Raceway would be precluded by the collective action alternatives involving the LFTRC at Route 15 resulting in the loss of a valued recreational resource. The NAVMAG LFTRCs would have significant impacts on the ambient noise levels at recreational resources in the vicinity.

The cantonment components, 2010 ROD-Related Actions (Section 6.2) and the additive actions (Section 6.2) would have less than significant impacts on recreational resources due to an anticipated increase in the use of recreational facilities throughout Guam than impacts to specific recreational resources.

**Reasonably Foreseeable Actions that Affect Recreational Resources.** One reasonably foreseeable project has the potential to contribute to a cumulative effect to recreational resources on Guam, Sigua Highlands (C-47) because the project is growth inducing for that area (see Table 7.6-1).

**Potential Cumulative Effects.** Several of the listed projects appear to have a recreational component that would create new recreational opportunities or increase capacity. The collective action alternative would have an additive cumulative impact on recreational resources in conjunction with increased tourism and other DOD mission changes because they would increase the on-island population. Increases in recreational resources use would likely occur at beaches and parks, scenic points, historic and cultural
sites, dive spots, trails, day use resorts, golf courses, sailing venues, on installations, and the rest of the island alike. Guam’s tropical weather encourages year-round use of recreational resources by residents and visitors. Foreseeable impacts include inadequate or overly crowded facilities such as parking, picnic shelters, restrooms, showers, and boat mooring facilities. Moreover, an eroded sense of enjoyment, due to increased competition for opportunities among users, would result at most recreational facilities (e.g., golf courses on installations, and popular dive spots). Lastly, an increase in the number of users could accelerate deterioration of existing facilities.

There will be cumulative effects associated with the collective action alternatives and the actions of other federal agencies, local governments, and the private sector on recreational resources on Guam. The magnitude of the effect is moderate (see Table 7.6-2) because there may be thresholds of recreational resource health but they are for specific recreational sites or activities. The pressure on recreational resources could be adaptively managed. Long-term impacts could be reversed if there are appropriate resources.

Need for Mitigation. Potential mitigation measures proposed for avoiding or reducing impacts to resources are listed in Tables 4.7-1 and 5.7-1. No additional mitigation measures for cumulative effects are proposed.

7.7.8 Terrestrial Biological Resources

Current Health and Historical Context. As summarized in Chapters 3, 4, and 5 of this SEIS, and in detail in the 2010 Final EIS, the terrestrial biological health on Guam is declining. The effect of pre-colonial activities on the current health of Guam’s terrestrial biological resources is unknown. During the Spanish Period (1668-1899) there were introductions and an increase of domesticated animals (i.e., water buffalo, pigs, goats, and deer). Introduced ungulates have significantly impacted native forests by consuming seeds, fruits and foliage and trampling plants. Feral pigs also cause additional damage by wallowing and rooting.

WWII physically destroyed extensive areas of habitat (due to war actions and construction) along with continued clearings associated with agriculture (i.e., crops and grazing). Shortly after WWII, the brown treesnake was inadvertently introduced to the island and by the late 1960s had spread throughout Guam (Section 1.3.3).

Existing stressors (e.g., tropical storms, typhoons, invasive species, diseases, wildfires, development, and poaching) continue to degrade habitat quality, population resiliency, and contribute to the trend of declining health of terrestrial biological resources. Ongoing efforts to manage terrestrial resources on military lands and non-federally controlled lands would continue to reduce the rate of decline.

Fewer than 1,000 threatened Mariana fruit bats were believed to occur on Guam in 1972 and less than 100 bats from 1974 to 1977. The most recent surveys suggest that fewer than 50 bats remain on Guam. Hunting pressure is largely responsible for the decline. Although hunting is illegal, it remains a threat.

The endangered Guam rail and Guam Micronesian kingfisher are believed to have been extirpated in the wild by 1985 and 1988, respectively. Both species were close to becoming extinct along with the majority of Guam’s other avifauna as a direct result of predation by the introduced brown treesnake. The Guam rail exists primarily in captivity on Guam and in mainland zoos. Guam rails were introduced onto Rota, CNMI in 1989 and onto Cocos Island, off the southern coast of Guam, in 2011. The Guam Micronesian kingfisher is now found only in captivity on Guam and at mainland zoos. Research and management efforts continue so that wild populations of Guam rails and Guam Micronesian kingfishers may eventually be reestablished on Guam.
Historically on Guam, the endangered Mariana crow was found throughout forested areas, and was considered common into the early 1960s. As of 2012, the Mariana crow is considered extirpated in the wild on Guam. The closest population of crows is on the island of Rota, north of Guam. Predation by brown tree snakes, rats, and monitor lizards prevents recovery.

Fifty-eight recently completed projects have the potential to contribute to adverse cumulative effect to terrestrial biological resources on Guam (see Table 7.6-1). The primary impact from these projects would be the potential loss of native habitat and the increased potential for the spread of invasive species. One project may have a beneficial impact, Ungulate Fencing (N-24).

Sixty-seven present projects have the potential to contribute to an adverse cumulative effect to terrestrial biological resources on Guam (see Table 7.6-1). This would be primarily due to the potential loss of native habitat and the increased potential for the spread of invasive species. Reforestation of Masso Reservoir (AH-2) could have a beneficial impact on terrestrial biology.

Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect. As summarized in Tables 7.4-1 and 7.6-2, the impact on terrestrial biological resources would be significant and mitigable for all of the collective action alternatives. All five resource areas assessed (e.g., vegetation, terrestrial conservation areas, native wildlife, federal special-status species, Guam special-status species) would be significantly impacted by the direct and indirect impacts of the LFTRC and cantonment pairings, except there would be a less than significant impact on native vegetation for all pairings. The adverse impacts would occur during construction and operations phases. Significant potentially mitigable impacts were also identified for the 2010 ROD-Related Actions (Section 6.2). The additive impact associated with the proposed IT/COMM infrastructure was determined to be less than significant (Section 6.1).

All collective action alternatives convert limestone forest to developed area and the greatest acreage affected is associated with the cantonment components and 2010 ROD-Related Actions. Overlay refuge areas would be adversely affected under all collective action alternatives. Federal special-status species that would be impacted include the Mariana fruit bat, Mariana crow, Guam Micronesian kingfisher, the Guam rail and the Serianthes tree. The impact on individual species varies among the collective action alternatives.

Reasonably Foreseeable Actions that Affect Terrestrial Biological Resources. Fifteen reasonably foreseeable projects have the potential to contribute to an adverse cumulative effect to terrestrial biological resources on Guam (Table 7.6-1). This would be primarily due to the potential loss of native habitat and the increased potential for the spread of invasive species. Examples of projects with potential adverse impacts include Sigua Highlands (C-47), Route 4 Curve Widening (S-28), and 60 MW power Plant (G-6).

Potential Cumulative Effects. All new development requiring vegetation clearing has potential to impact terrestrial biological resources. There are federally and locally established habitat conservation areas and increases in human population or other noise generating activities near these areas can disturb the populations of species that are to be protected in the conservation areas.

There would be cumulative effects associated with the collective action alternatives in conjunction with recently completed, present, and reasonably foreseeable actions. The additive impact of would be strong (see Table 7.6-2) because the impacts could be long-term and difficult to reverse. Many of these projects, developments, and actions, and their impacts on terrestrial biological resources cannot be determined with specificity at this time. Most of the projects require ground disturbance, and the assumption is that
terrestrial biological resources would be affected. The terrestrial biological resource health on Guam would continue to decline, and threatened and endangered species would continue to be vulnerable to natural and anthropogenic stressors. Because the development area of the collective action alternatives is presumably larger than that of the recently completed, present, and reasonably foreseeable actions, the additive cumulative impacts are primarily due to the direct impacts of the collective action alternatives.

Need for Mitigation. Potential mitigation measures for the impacts due to the collective action alternatives are proposed in Tables 4.7-1 and 5.7-1. GovGuam reviews public, private, and commercial development proposals for potential impacts to terrestrial biological resources. The USFWS monitors GovGuam, private, and commercial development proposals and periodically adjusts the acreage of available recovery habitat island-wide. This adjustment is used to determine the impact of federal development proposals that must comply with section 7 of the ESA and may result in mitigation for federal development proposals. The USFWS and GovGuam review DoD and other federal development proposals and mitigation is developed through the consultation process. There are local and federal initiatives and protocols to prevent the introduction of non-native species. There are local and federal conservation and restoration efforts. No additional mitigation is proposed for cumulative effects to terrestrial biological resources.

As part of the ESA section 7 consultation process, the DON and the USFWS entered into an MOA, which would, if the preferred alternative is chosen, facilitate kingfisher conservation goals. In the MOA, the DON agreed to designate approximately 5,234 acres (2,118 ha) under the custody and control of the DoD in northern Guam to a status that will provide durable habitat protection needed to support native habitat restoration and land management for the survival and recovery of the kingfisher. Consistent with the JRM INRMP developed in accordance with Section 101 of the Sikes Act, the DON agreed to actively restore native habitat and manage, in collaboration with the USFWS, the 5,234 acres (2,118 ha) consistent with DoD’s obligations under ESA section 7(a) and the Sikes Act to benefit the survival and recovery of the kingfisher. The DON would work cooperatively with the USFWS to identify, develop and implement specific management activities and projects on these 5,234 acres (2,118 ha) to support the reintroduction and recovery of the kingfisher.

These 5,234 acres (2,118 ha) have been identified by the USFWS as habitat for the kingfisher and needed to offset impacts of the proposed action. The DON and USFWS recognize that the designation of the 5,234 acres (2,118 ha) may also provide a conservation benefit to other ESA-listed species with similar habitat requirements (e.g., Mariana crow, Mariana fruit bat).

7.7.9 Marine Biological Resources

Current Health and Historical Context. As summarized in Sections 3.9, 4.2.9, 5.5.9, and in this section, the overall health of Guam’s reefs has declined over time, with impacts from global and local stressors contributing to a significant decline over recent decades. The average live coral cover was approximately 50% in the 1960s, but dwindled to less than 25% by the 1990s, with only a few areas having over 50% live cover. In the past, however, Guam’s reefs have recovered after drastic declines. For example, an outbreak of the crown-of-thorns starfish in the early 1970s reduced coral cover in some areas from 50-60% to less than 1%, but 12 years later, live coral cover was restored to pre-1970s conditions. The more common trend, however, is the decline of Guam’s reefs over the past 40 years, consistent with a general global decline of this resource.

Prior to Spanish conquest, the Chamorro and other Pacific societies retained property rights within the family that extended out to sea. While fishing occurred, it was likely done at sustainable levels. Harvesting of sea turtles and their eggs also occurred. The effect of pre-WWII events on the current
health of Guam’s marine biological resources is unknown. There was likely coral damage due to storm and wave events, but low levels of human-induced stress because population and industry levels were much lower than today.

The creation of Inner and Outer Apra Harbor during WWII required extensive dredge and fill. The navigational approach to Inner Apra Harbor was dredged. In addition to the direct physical impact on marine resources due to the war, indirect impacts resulted from an increase in soil erosion as described under the terrestrial biological resources section. The sediment load in the coastal waters likely had an impact on the health of the reefs. Post-WWII dredging in Apra Harbor resulted in a decline of coral communities and compensatory mitigation proposals are being implemented to restore the ecosystem function in other watersheds.

Since WWII, the health of marine biological resources has been affected by an increasing population, and associated recreational, industrial and commercial operations that impact the natural environment. More recently, the most serious threats to Guam’s reef health have been identified as sedimentation (from illegal wildfires, improper development, and upland erosion), stormwater runoff and associated pollutants such as fertilizers and oil (from inadequate protections during coastal development and insufficient stormwater management practices and infrastructure), and overfishing.

A variety of land-based activities have contributed to nutrient input to nearshore waters. A 2010 assessment by GEPA determined that while most of the 24 assessed bays met water quality guidelines for recreational activities and harvesting, 11 of the bays were impaired. Over 700 swimming advisories due to bacterial counts in marine waters were issued in 2009, likely stemming from faulty septic tanks and non-compliance by treatment facilities with NPDES regulations for various parameters. In 2009, two treatment plants that had previously been the source of untreated sewage into nearshore waters were renovated to repair the leaks and extend the outfall pipes further offshore.

Adding to these stressors are the more recent emergences of crown of thorns outbreaks, coral disease, and coral bleaching. There are six coral diseases that affect Guam’s reefs, with over 10% of corals observed in one study, affected by at least one disease.

A total of nine special-status species potentially occur within the nearshore waters of Guam: three fish, three sea turtles, and three coral species (Tables 3.9.1-1 and 3.9.1-2). In April 2013, NMFS found that the Indo-West Pacific Distinct Population Segment of the scalloped hammerhead shark be listed as threatened (NMFS 2014a) under the ESA. Information on the distribution of scalloped hammerhead sharks around Guam is limited, but Guam’s Outer Apra Harbor has been noted for neonate and juvenile aggregations. The humphead wrasse and bumphead parrotfish are NMFS Species of Concern. NMFS announced in November 2012 that the bumphead parrotfish did not warrant listing as threatened or endangered under the ESA following a status review (NMFS 2012a). NMFS also found in September 2014 that the humphead wrasse did not warrant listing as threatened or endangered under the ESA following a status review, but it is virtually extinct from the waters around Guam (NMFS 2014b). The ESA-listed green and hawksbill sea turtles are threatened by direct harvesting of eggs or adults, beach cleaning and replenishment, recreational activities, debris, incidental take from fishing, and seagrass degradation.

In August 2014, NMFS found three species of coral occurring in the waters surrounding Guam (Acropora globiceps, Acropora retusa, and Seriatopora aculeata) merited listing as threatened under the ESA (NMFS 2014c). The conclusion of a recent State of the Coral Reef Ecosystem on Guam assessment was that the health of Guam’s coral reefs varies significantly. Reefs unaffected by sediment and nutrient loading, such as those in the northern part of the island and some coastal areas in the south, have healthy coral communities. Guam’s reefs have been spared from large-scale bleaching events and coral diseases.
which are prevalent in so many parts of the world. A number of Guam’s reefs are impacted by land-based sources of pollution and over-fishing. Guam identified land-based sources of pollution as its number one priority focus area in 2002. Sedimentation, algal overgrowth due to decreased fish stocks, and low recruitment rates of both corals and fish are important issues that must also be addressed. Big Blue Reef in Apra Harbor is considered one of the healthiest reefs in the harbor due to the reef’s protection from water quality factors associated with Inner Apra Harbor and ship-induced sediment resuspension that impact other reef systems in the harbor. Reefs off Dry Dock Island, which was artificially created during WWII, are considered to also be among the healthiest reefs in the harbor, primarily due to protection from stressors. In contrast, the coral reef along Polaris Point, which was also constructed during WWII, is of marginal quality and has the greatest signs of stress, including high levels of total suspended solids likely derived from watershed discharge. Recreational activities result in physical damage to coral reefs, and fish feeding by snorkelers and divers can alter fish behavior. Recent studies conducted in support of this SEIS identify evidence of anchor and/or anchor chain damage to coral in Apra Harbor, including the formation of a rubble field on the southern side of the floating dry dock. Movement of mooring chains on the southern side of the floating dry dock has produced a significant rubble field, although mooring chains on the northern (outer) side of the floating dry dock do not appear to have caused similar damage.

On a more global scale, the nine most important threats to reef-building corals include: ocean warming (high), disease (high), ocean acidification (medium-high), trophic impacts of fishing (medium), sedimentation (low-medium), nutrients (low-medium), sea-level rise (low-medium), predation (low), and collection and trade (low), as stated by the Coral Biological Review Team assembled to complete comprehensive status reviews of the 82 species of reef-building coral initial proposed for ESA-listing. Potential impacts from these threats to coral are related to the intensity and duration of the threat over time and space, and nearly all are expected to increase over the long term. Ocean warming, disease, and ocean acidification are discussed more under the “Potential Cumulative Effects” section below.

Sixteen recently completed projects have the potential to contribute to cumulative effects to marine biological resources on Guam (see Table 7.6-1). Nine of these projects could have a beneficial impact because they reduce erosion or improve infrastructure, such as, Northern District WWTP (N-32) and Construction of Golf Pier Pipeline Replacement (AH-16). Projects with potential adverse impacts are coastal projects: Gregorio D. Perez Dock A&B Steel Pile Extension and Water Blasting (C-19), and Kilo Wharf (AH-4).

Thirty present projects were identified and 23 of these could have a beneficial impact because they are infrastructure improvements, such as: Wastewater System Planning (G-12), Facilities Plan/Design for WWTP (G-13), Marine and Port Security Operations Center (AH-13), Old Agat Wastewater Collection (Phase II) (S-10), Hagåtña Sewage Treatment Plant Improvements and Effluent WWPS (C-42), Facilities Plan For Hagåtña STP Improvements and Effluent WWPS (C-41), and Modernization Program for Port Reconfiguration, Maintenance, and Repair (AH-11), and Northern District WWTP (N-32), Agaña Water Treatment Plant Interim Measures (C-43), and Wastewater Collection System Replacement/Rehabilitation Program (G-19). Projects with a potential adverse impact include new or improved wharves and piers, such as Gregorio D. Perez Marina Dock C repairs (C-40), military training ranges (MITT [G-23]) and port modernization program (AH-11).

Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Impact. As summarized in Tables 7.4-1 and 7.6-2, all of the collective action alternatives would result in less than significant long-term impacts to marine biological resources. These impacts are indirect and tend to be associated with the proposed population increase, which would increase pressure on marine
recreational resources around the island and increase the volume of wastewater effluent. With planned GovGuam improvements to wastewater treatment plants, there would be no impact on marine resources due to wastewater effluent in the long-term. There may be impacts to marine conservation areas that are adjacent to the cantonment alternatives but this would not apply to the Barrigada cantonment (Alternative D). Similarly, there would be no impact associated with the operations of the LFTRC alternatives at NAVMAG (Alternatives 2, 3, 4) because they are not affecting submerged lands. The less than significant impacts identified for these coastal LFTRCs are related to the remote chance that there would be rounds of ammunition that end up in the ocean. No training exercises in the water are planned; therefore, no direct impact to marine resources is anticipated.

The restricted public access to the NWF LFTRC SDZ could be viewed as a beneficial impact to marine resources because there would be reduced impacts on marine resources associated with recreational use. The 2010 ROD-Related Actions (Section 6.2) and the additive actions (Section 6.1) would have less than significant or no impact on marine biological resources. There would be direct short-term localized construction-related impacts associated with the Apra Harbor wharf improvements, but the impacts would not have a long-term impact on the health of the resource.

Reasonably Foreseeable Actions that Affect Marine Biological Resources. Two reasonably foreseeable future projects are anticipated to contribute to a cumulative effect to marine biological resources on Guam (see Table 7.6-1). X-Ray Wharf Improvements (AH-10) may have short-term adverse impacts to marine biological resources because there is in-water work. The Umatac-Merizo STP Replacement (S-18) would have a beneficial impact because it is in infrastructure improvement.

Potential Cumulative Effects. The collective action alternative impacts on marine biological resources are indirect and less than significant, and primarily associated with the proposed increase in island population. Two collective action alternatives have SDZs over water and there is slight potential for direct impact to individuals of a species but there would be no impact to the overall health of the population. Most of the recently completed, present, and reasonably foreseeable projects would have a beneficial impact on marine biology because they are sewer infrastructure improvement projects. MITT is an exception.

There would be a low additive cumulative effect (see Table 7.6-2) because the waterfront projects identified are few, the direct impacts would be localized, and there are regulatory controls to mitigate the impacts. The collective action alternatives would not impact the resiliency of marine biological resource health in responding to future stressors.

Need for Mitigation. Potential mitigation measures proposed for avoiding or reducing impacts to resources are listed in Tables 4.7-1 and 5.7-1. Additional mitigation measures may be considered based on consultations with regulatory agencies and will be discussed in the ROD, as appropriate.

7.7.10 Cultural Resources

Current Health and Historical Context. As summarized in Sections 3.10, 4.2.10, 5.5.10, and in detail in the 2010 Final EIS (Volume 2, Section 12.1: Affected Environment, pages 12-1 to 12-38), cultural resources include Pre-Contact and Post-Contact archaeological resources, architectural resources and traditional cultural properties. The main Mariana Islands were settled before 1500 B.C. The Pre-Latte period was from 1500 B.C. to 1000 A.D.; evidence of residency and community composition is difficult to identify. The Latte Period (1000 A.D. to 1300 A.D.) is distinguished by the presence of latte stone structures. The Post-Contact period begins in 1521 A.D. with Magellan’s landing. Subsequently, disease and war decimated the local population, reducing it from 40,000 in 1668 to 1,800 in 1690. In the 19th
century, Guam was ceded to the U.S. by Spain. Between 1898 and 1941, Guam served as a coaling and fueling station for Naval ships and as a landing place for the Pan-American transpacific air clippers. In 1941, Japan attacked Guam and in 1944, the U.S. commenced an intensive bombardment. After the U.S. captured the island there was a massive build-up of military forces, including construction of five new airfields. Since the 1960s, tourism has been an important industry.

Since 1966, most potential impacts to cultural resources as defined under NEPA have been evaluated consistent with NHPA and the Criteria of Adverse Effect set forth at 36 CFR 800.5. Overall the health of cultural resources can be impacted as a result of inadvertent disturbance, construction activities, and natural degradation and damage due to erosion. On Guam, for example, prior to the enactment of NHPA and NEPA, activities related to WWII resulted in a general degradation of the health of cultural resources. Today, while some areas have been heavily impacted, there are other areas that remain where cultural resources are significantly intact. In consideration of this, the overall health of cultural resources is moderate.

Sixty-one recently completed projects with the potential to contribute to a cumulative effect to cultural resources on Guam were identified (see Table 7.6-1). Any project that results in ground disturbance could contribute to a cumulative effect on cultural resources, such as Ukudu Workforce Village (e.g., N-28), roadway construction or improvements (e.g., Route 25 [C-6]), or structures like the Veterans Clinic (C-3) and the Bayview 5 Luxury Hotel (C-4). No projects were identified that would have a beneficial effect on cultural resources.

Sixty-eight present projects with the potential to contribute to a cumulative effect on cultural resources on Guam were identified (see Table 7.6-1). Many of these projects are residential construction (e.g., Emerald Ocean View Park [C-21]) or roadway construction or improvements (e.g., Route 4, Togcha River to Ipan beach park [S-20]), but there are a variety of other activities that could have an adverse cumulative effect on the resources, such as Lateral Conversion of Powerlines to Underground Lines (G-11). One project, the new Guam Museum (C-24) would have a beneficial impact on cultural education.

Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect. All collective action alternatives would result in significant mitigable impacts to Guam’s cultural resources as a result of the cantonment/family housing and LFTRC component, as summarized in Tables 7.4-1 and 7.6-2. The exception is the significant impact identified for the collective action alternatives that involve the NWF LFTRC (A-5, B-5, C-5, D-5, and E-5), due to the restriction of public access to a NRHP-eligible site at Ritidian Unit of the Guam NWR. Table 6.2.4-2 summarizes the collective action impacts, including the numbers of historic properties affected. Direct construction impacts alone would result in adverse effects to a minimum of 20 known historic properties under collective action alternative D-1 and a maximum of 49 historic properties for collective action alternative A-5. In addition, there are undetermined effects to historic properties and archaeological sites that have not been evaluated and impacts to culturally important natural resources. The ROD-Related Actions contribute to the impact on cultural resources, but the majority of the impact would be related to the cantonment/housing and LFTRC development.

Each of the collective action alternatives would contribute to the decline in preservation of cultural resources. Other factors unrelated to the project, such as vandalism and weathering, would continue to adversely impact cultural resources.

Reasonably Foreseeable Actions that Affect Cultural Resources. Fourteen reasonably foreseeable projects are anticipated to contribute to a cumulative effect to cultural resources on Guam (see Table 7.6-1)
because they are likely to involve ground disturbance. These projects include road construction (e.g., Route 17 Rehabilitation & Widening [S-27]), and Sigua Highlands (C-47).

**Potential Cumulative Effects.** There would be cumulative effects associated with the collective action alternatives and the recently completed, present, and reasonably foreseeable actions of other federal agencies, local governments, and the private sector on cultural resources on Guam. These impacts may be linked to projects, developments, and actions that do not meet the criteria for a federal undertaking as defined in the NHPA. The impacts of these actions cannot be determined with specificity at this time.

Implementation of the collective action alternatives in conjunction with recently completed, present, and reasonably foreseeable actions would have a cumulative effect on cultural resources. The magnitude of the impact would be strong because the impacts are long-term and generally irreversible. Disturbance or destruction of these cultural resources would further diminish the regional historic record, thus decreasing the potential of its overall research contribution. Reduced access to cultural sites, whether for cultural practices or academic study, would also diminish the cultural resources of Guam.

**Need for Mitigation.** Potential mitigation for the impacts of the collective action alternatives is described in Section 6.2 of this SEIS. To the degree possible, impacts to historic properties and other significant cultural resources would be avoided or minimized during the planning process. If avoidance is not possible, potential mitigation measures to resolve adverse impacts to historic properties and reduce adverse impacts to cultural resources resulting from the implementation of collective actions would include the following:

- support Guam SHPO’s update of the Guam Historic Preservation Plan (GHPP);
- beginning in 2017, update the Guam Synthesis with information from DoD studies in concert with the GHPP;
- nominate two or more historic properties on DoD land per year for listing in the NRHP;
- In accordance with the 2011 PA, support construction of a Guam Cultural Repository and seek congressional authorization to transfer DoD funding for the construction. The $12,000,000 appropriated under the FY 2012 Consolidated Appropriations Act (Public Law 112-74) for a Guam Cultural Repository facility remains in place. The appropriation provides funding for a repository for curation of archaeological collections on Guam and to serve as a source of information on Guam history and culture; and
- advocate to other federal agencies to provide funding for the Guam Museum Complex.

With the implementation of these measures and processes as outlined in the 2011 PA, it is expected that significant cumulative impacts would be partially mitigated but not to a less than significant level.

No additional mitigation measures are proposed for cumulative effects on cultural resources.

**7.7.11 Visual Resources**

**Current Health and Historical Context.** As summarized in Sections 3.11, 4.2.11, 5.5.11, and in this section, the visual quality of Guam prior to WWII was presumably high due to the prevalence of open space. Urban development and introduction of invasive species are likely the most notable cause for change in visual environments; the physical characteristics of a development as well as location, influence the resulting visual impact. Natural disasters, such as typhoons and earthquakes, contribute to the degradation of the appearance of existing developments. Some developments are abandoned and fall into disrepair with an adverse impact on visual resources. When the economy is good, there is a tendency for increased development or property improvement. Conversely, during hard economic times, buildings are not maintained or are abandoned. The visual resources trend over time is not linear, but is influenced by
critical events. In general, there is a trend toward increased development. GovGuam reviews development proposals to verify they are consistent with zoning objectives with respect to density and do not interfere with valued scenic views. There is no regulatory threshold regarding visual health of Guam.

Eleven recently completed projects that affect visual resources on Guam are identified in Table 7.6. Those with potential adverse impacts include: Workforce Housing (N-10), Talo Verde Estates (C-2), Bayview 5 Hotel (C-4), and Amusement Park (C-12). These are all projects that alter the visual experience from adjacent roadways relative to what was previously on the various sites. Layon Landfill (S-3) affects an area that was formerly open space; however, there is little traffic in the area. One project could have a beneficial visual impact: Upgrade of Existing 14 Megavolt Ampere Power Transformer to 30 Megavolt Ampere and Underground Line (G-5).

Nineteen present projects that affect visual resources on Guam are identified in Table 7.6. Two of these projects could have a beneficial impact because it involves the lateral conversion of power lines to underground lines (G-11) and Reforestation of Masso Reservoir (AH-2). GovGuam and UoG Wind Turbines (S-4 and C-32) are tall features that are visible from a distance and may impact views. Anti-terrorism/Force Protection Perimeter Fencing is an example of a military base project that would be visible to the community.

Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect. As summarized in Tables 7.4 and 7.6, collective action alternatives would have impacts on visual resources that range from less than significant to significant. The adverse impacts are related to the LFTRC component of the collective action alternatives. The collective action alternatives A-5, B-5, C-5, D-5, E-5, A-2, B-2, C-2, D-2, and E-2 would have less than significant impacts on visual resources due to large-scale development with limited public views. The significant impacts associated with the remaining alternatives include two of the NAVMAG LFTRC alternatives that would be visible from Jumullong Manglo Overlook and Mount Lamalam and their associated hiking trails to two of NAVMAG LFTRC (LFTRC Alternatives 3 and 4). Significant mitigable direct impacts would be due to alteration of the views from Route 15 to the proposed LFTRC (Alternative 1) Potential mitigation measures are proposed to restore/maintain natural vegetation to the extent practical. Less than significant impacts would be associated with all collective action alternatives due to increased building density for cantonment/family housing. The development would be designed to be consistent with the 2011 Installation Insurance Plan. While the base would not be accessible to the public, some features would be publicly-visible including the entrance gates, perimeter fencing and peripheral landscaping and vertical infrastructure such as light posts and water tanks. These, and the remaining features of the new base, would present a united design template as outlined in the Installation Insurance Plan. No significant impacts to visual resources were identified for the 2010 ROD-Related Actions (Section 6.2) and the additive impacts (Section 6.1). The collective action alternatives would not contribute appreciably to the declining trend in visual resources. Other factors unrelated to the project, such as natural disasters and economic downturns, would continue to adversely impact visual resources.

Reasonably Foreseeable Actions that Affect Visual Resources. Three reasonably foreseeable future projects are anticipated to contribute to a cumulative effect to visual resources on Guam (see Table 7.6). The one public utility project that might adversely impact open space is the GovGuam 60 MW Power Plant (G-6). The remaining projects include large development proposals that could impact open space, such as: Sigua Highlands (C-47), and the Territorial Prison (G-10).

Potential Cumulative Effects. There would be cumulative effects associated with the collective action alternatives in conjunction with recently completed, present, and reasonably foreseeable actions of other
federal agencies, local governments, and the private sector on visual resources on Guam. The implementation of any development project would likely remove open space and potentially result in an adverse impact. Some projects may replace abandoned or deteriorated buildings that would result in an improvement to visual resources. The GovGuam reviews development proposals and impacts to valued scenic viewpoints would be identified and considered in the permit application process.

Visual impacts are geographically limited. The recently completed, present, and reasonably foreseeable actions in the southern part of Guam (Figure 7.5-4) are unlikely to contribute to a cumulative impact in conjunction with the NAVMAG collective action alternatives in the south. There would be no cumulative impact associated with the 2010 ROD-Related Actions in Inner Apra Harbor. The Barrigada cantonment (Alternative D) is located in central Guam (Figure 7.5-2) and open space would be reduced, but most of the actions identified in the area are low profile road improvement projects; therefore, no cumulative impact is anticipated on the visual resources in Central Guam. Northern Guam has the greatest potential for cumulative impacts due to the number of recently completed, present, and reasonably foreseeable actions and the potential for both the cantonment, LFTRC and the Air Combat Element of the 2010 ROD-Related Actions to be located in the north. However, most of the visual impact of the collective action alternatives in the north would occur within the installation boundary and would not be visible to the public.

For these reasons, there would be a low additive cumulative effect between the collective action alternatives that would be located within DoD installations and the recently completed, present, and reasonably foreseeable future projects with respect to impacts on visual resources (see Table 7.6-2). The low additive impact would be limited to the northern part of Guam. No additive impact is anticipated to other areas of Guam.

Need for Mitigation. Potential mitigation measures proposed for avoiding or reducing impacts to resources are listed in Tables 4.7-1 and 5.7-1. No additional mitigation measures for cumulative effects are proposed.

7.7.12 Ground Transportation

Current Health and Historical Context. Sections 3.12, 4.2.12, 5.5.12 provide information on current health of the resource. Periodic master plans and roadway studies have been prepared by GovGuam to assess roadway and traffic conditions to identify and prioritize roadway and traffic improvement projects. The most recent comprehensive planning effort is the 2030 Guam Transportation Plan, published in December 2008. Forecasts for population and employment through the year 2030 were used to develop an integrated strategy for a multimodal (e.g., vehicle, pedestrian, mass transit) transportation system. The roadway conditions vary from acceptable (no major safety issues), to poor (minor safety issues) to unacceptable. There is a bus system that includes a fixed route, and service for the handicapped; however, there are concerns with scheduling that result in poor ridership. Outside of military installations, designated bicycle lanes are not available and sidewalks are limited to main routes in urbanized areas.

The traffic on roadways is driven by island population and employment related to land use development. Roadway condition is a function of construction material, age, vehicle type, traffic volume, and natural influences such as climate, typhoons, and earthquakes. Since 1950, the population has continued to increase on Guam. The future trends in population growth are expected to increase and continue through 2030; however, the Guam Transportation Plan considered increases related to the military relocation. The roads serving Dededo and Tamuning are currently the most congested because they serve major residential and employment centers. Roadway improvements were identified to address projected 2030 traffic issues, and projects would be implemented as funds become available. Sections 4.2.12 and 5.5.12
describe the baseline conditions for the specific roadways that would be affected by the collective action alternatives, assuming the improvements identified in the Plan are implemented. Island-wide there are an estimated 12 intersections in 2014 and 24 in 2030 that would have the poorest LOS. Although some projects are programmed for funding, traffic conditions are projected to deteriorate on Guam. The natural influences on roadway conditions would continue into the future.

There are private shopping and tour buses that operate among Micronesian Mall, KMART, Guam Premier Outlets and other destinations. The recently established GRTA is responsible for public transit functions. It approved the Guam Transit Business Plan in January 2010, which includes purchasing new buses, constructing a bus maintenance facility, and modifying the bus schedule. Pending funding, a future trend is for improvements to bus service. Guam Public Law requires the consideration and construction of bicycle and pedestrian paths with all new road construction projects. The 2030 Guam Transportation Plan also identifies a plan for bicycle and pedestrian facilities. New developments and roadway projects would include pedestrian and bicycle facilities and improve pedestrian and bicycle options; however, without adequate funding, the existing deficiencies in facilities are likely to continue. The FHWA and other federal transit funding can be used for bicycle lanes.

Twenty-nine recently completed projects with the potential to contribute to a cumulative effect to roadways on Guam were identified (see Table 7.6-1). Most (20) of these projects would have a beneficial impact because they are roadway improvement projects that would improve traffic LOS, including Route 25 (C-6) and Route 8/10/16 Tri-intersection (C-16). Residential construction (e.g., N-10) and hotel development (e.g., C-4) would have an adverse impact to roadways because they induce traffic.

Thirty-two present projects with the potential to contribute to a cumulative effect to roadways on Guam were identified (see Table 7.6-1) and 17 are likely to have a beneficial impact. These beneficial projects include, Route 1-8 Intersection Improvements & Agaña Bridges Replacement (C-29). Residential construction (e.g., Sagan Bonita [C-26]) and Guam Regional Medical Centers (e.g., N-38) may have an adverse impact to roadways because they induce traffic.

Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect. As summarized in Section 6.2 of this SEIS, the collective action alternatives would have less than significant impacts on off-base traffic LOS. Less than significant impacts were identified for increased potential for collisions with bicyclists and pedestrians under all collective action alternatives. No long-term impacts were identified to on-base traffic. The 2010 ROD-Related Actions would have less than significant impacts on traffic.

The significant direct impact on LOS is due to the pairing of each LFTRC and cantonment/family housing alternative and most of the impacts are mitigable to less than significant (see Additive Impacts, Section 6.1). Specific roadway improvement projects were identified as potential mitigation for significant impacts identified for Finegayan and Finegayan/South Finegayan cantonment/family housing alternatives (i.e., A-1, A-2, A-3, A-4, A-5; B-1, B-2, B-3, B-4, B-5; E-1, E-2, E-3, E-4, E-5). With implementation of the potential mitigation measures described in Section 6.1, traffic would improve to an acceptable LOS for affected roadways and intersections. The cantonment alternatives include bike lanes that are segregated from vehicle lanes resulting in a beneficial impact on multimodal traffic and safety. Potential mitigation measures were not identified for the significant impacts at the remaining alternatives, involving cantonment at AAFB or Barrigada.

Reasonably Foreseeable Actions that Affect Ground Transportation. Eleven out of 12 reasonably foreseeable projects are anticipated to have a beneficial impact on ground transportation, because they are roadway improvement projects (see Table 7.6-1). Examples of beneficial projects include: Route 26/25
Intersection Improvements (C-31), Route 10A, Route 1/Tiyun Intersection and Route 5 Rehabilitation & Widening (S-29). The Sigua Highlands project (C-47) would have an adverse impact on traffic because it would induce more traffic into the area.

**Potential Cumulative Effects.** There would be cumulative ground transportation effects associated with the collective action alternatives in conjunction with recently completed, present, and reasonably foreseeable projects that induce traffic. Very few growth-inducing projects were identified among the recently completed, present, and reasonably foreseeable projects. The adverse effects are adaptively managed through roadway improvement projects. A large number of roadway improvement projects throughout the island are already planned by GovGuam DPW to address LOS deficiencies, but these are subject to funding availability. The magnitude of additive impact resulting from every collective action alternatives would be strong (see Table 7.6-2) because the infrastructure improvement projects are subject to funding availability and there may be a lag time before the improvement projects are constructed.

**Need for Mitigation.** Specific roadway improvement projects are proposed in Chapter 6.1 of this SEIS as potential mitigation measures for the significant impacts due to the collective action alternatives. GovGuam continues to update their transportation program to address existing LOS deficiencies. No additional mitigation measures are proposed for cumulative effects.

### 7.7.13 Marine Transportation

**Current Health and Historical Context.** As summarized in Chapters 3, 4 and 5, and in the 2010 Final EIS, during WWII, port capacity was greatly expanded. As new military ships are brought to Guam and military missions change, there is always the potential for an increase in military marine traffic. The commercial traffic is a function of population and general economic health of the island. The number of non-military vessels visiting the Port of Guam would continue to reflect the need to service the population and economic growth.

Three out of five recently completed projects have the potential to contribute to a beneficial cumulative effect to marine transportation on Guam (see Table 7.6-1) because they are port improvement projects, including Kilo Wharf Extension (AH-4). Population inducing projects may increase the shipping of goods, including PRTC Warrior Barracks (N-12).

Six out of 11 present projects have the potential to contribute to a beneficial cumulative effect to marine transportation on Guam (see Table 7.6-1), including Romeo Wharf Improvements (AH-21), Guam Port Modernization Projects (AH-11), and GovGuam Agat Marina Dock A Repair & Renovation (S-16). Projects with potential to increase shipping of goods include, Pacific Air Power Resiliency (N-26).

**Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect.** As summarized in Tables 7.4-1 and 7.6-2, each of the collective action alternatives would result in less than significant impacts to Guam’s marine transportation. There would be an increase in vessel traffic to the Port of Guam that would be the same for each of the collective action alternatives. This increase would not exceed the port’s capacity. There has been a steady and substantial decline in the number of commercial vessels visiting the Port of Guam from 1995 through 2008 (2,924 to 1,022 vessels), the additional traffic that would be associated with the collective action alternatives would be well below the 1995 peak number of vessels visiting the Port of Guam.

**Reasonably Foreseeable Actions that Affect Marine Transportation.** One reasonably foreseeable future project is anticipated to beneficially contribute to a cumulative effect to marine transportation at Guam, X-Ray Wharf (AH-10) (see Table 7.6-1).
Potential Cumulative Effects. There would be an additive impact between the collective action alternatives and the recently completed, present, and reasonably foreseeable future projects, but the magnitude of additive impact resulting from the collective action alternatives would be low (see Table 7.6-2). Although the volume of goods may increase to support the increases in population, the increase in ship traffic is considerably lower than vessel traffic experienced in the late 1990s. The commercial port is not at risk of being unable to meet the anticipated increases in demand.

Need for Mitigation. Potential mitigation measures proposed for avoiding or reducing impacts to resources are listed in Tables 4.7-1 and 5.7-1. No additional mitigation measures for cumulative effects are proposed.

7.7.14 Utilities

Current Health and Historical Context. As summarized in Chapters 3, 4, and 5, and in this section the trends in utility demand are tied to population growth and constructed facility growth that has generally increased over time. Electrical power demand is typically estimated based on the square footage of constructed facilities. Water and wastewater quantities are forecast using population and industrial uses. Solid waste quantities are estimated using population, commercial/industrial operations, and construction activity for C&D debris and green waste.

In the utility studies prepared for this SEIS, the forecast electrical power demand was based on planned DoD projects and their square footage/type of facility. In addition, the analysis forecast the electrical power demand increases for civilian projects based on population growth forecast, both induced growth including construction workforce and organic civilian growth forecast (independent of the proposed Marine Corps Relocation). Based on these estimates, there is sufficient power generation capacity to meet current and forecast demands through the year 2028. GPA may have a different approach to civilian power demand forecasting that could affect their future plans.

The GWA potable water distribution system is identified as poor; it does not meet basic flow and pressure requirements for all customers. GWA is currently operating under a stipulated order last amended in October 2011. A program management consultant has been contracted to manage the required improvement projects, and some projects have been completed while others are in progress. In addition, the leak detection and repair program has yielded results based on GWA observed positive operational characteristics. However, it is too soon to confirm these observations. The recently completed USEPA NEIC Water Inspection Report revealed continued deficiencies in the GWA potable water system.

The GWA wastewater infrastructure has had a legacy of deferred maintenance and minimal capital improvements causing the systems to deteriorate over the years and resulting in violations of NPDES permit limits at WWTPs. The wastewater systems would continue to degrade until capital improvements are made. The current major wastewater compliance requirements for GWA are covered under the 2011 Court Order, significant findings for wastewater from a USEPA NEIC inspection conducted in 2012, and 2013 NPDES permits requiring treatment system upgrades for the Northern District WWTP and Agaña WWTP.

In the years since the 2010 Final EIS, the GWA has made progress in complying with the 2011 Court Order, including addressing significant findings from the 2012 USEPA NEIC inspection. However, implementation of capital improvement projects and improvements to the operation and maintenance of the existing GWA wastewater infrastructure are in the initial stages and will require several years and significant funding to achieve full compliance. A program management consultant has been contracted by the GWA to assist in the management of the required court ordered projects. Some projects have been
completed while others are in progress. The Northern District WWTP and the Agaña WWTP primary treatment capabilities have been improved subsequent to the 2010 Final EIS through chemically enhanced treatment. The effluent today is of better quality than in 2010. However, USEPA issued the 2013 permits requiring effluent quality be consistent with secondary treatment and Guam Water Quality Standards, including those for nutrients. The 2013 NPDES permits for the Northern District WWTP and Agaña WWTP require upgrading these plants to achieve compliance. These upgrades are required whether or not the proposed action proceeds and will result in improved effluent and receiving water quality.

The DON proposes to explore ways to resolve key solid waste issues, specifically the status of the Naval Base Guam Landfill permit and handling of special wastes not accepted at Layon Landfill, through the Solid Waste Working Group that was established with USEPA and GEPA on July 24, 2014. During the September 19, 2014 meeting of the Solid Waste Working Group, GEPA indicated that they will formally respond to DON correspondence with regards to issues relative to the Naval Base Guam Landfill. The Layon Landfill and the permitted private hardfill facilities are operating within their regulatory requirements. The proposed action would be in compliance with all applicable GEPA solid waste permit terms and conditions that routinely include specific measures to protect human health and the environment. All other projects on Guam would utilize permitted solid waste management and disposal facilities.

Of 19 recently completed projects (see Table 7.6-1), 15 would have a beneficial impact on utilities because they are infrastructure improvement projects, such as: Fiber Optic Installation (C-20), Deep Well Rehabilitation (G-17), Implement Groundwater Rule (G-16), Ugum Water Treatment Plant Refurbishment (S-6), and South Ramp Utilities Phase 2 (N-11). Population inducing projects may increase the demand on utilities, including PRTC Warrior Barracks (N-12).

Of the 31 identified present projects involving utility improvements (see Table 7.6-1), 29 could have a beneficial impact on utilities, including: Baza Gardens STP replacement (S-14), Wind Turbines (C-32, S-4), Wastewater Collection System Replacement/Rehabilitation Program (G-19), Hagåtña STP Improvements (C-41), Northern District WWTP (N-32), and Water Booster Pump Station (G-15). Projects with potential to increase demand on utilities include Pacific Air Power Resiliency (N-26).

Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect. As summarized in Tables 7.4-1 and 7.6-2, less than significant direct impacts were identified for power, solid waste and IT/COMM under all collective action alternatives. The Utilities direct and indirect impact analysis on infrastructure capacity addresses population growth and planned DoD projects through 2028; therefore, there may be an overestimate of the potential for cumulative impact on utilities in this section. The collective action alternatives would place a greater demand on these utilities but there is sufficient capacity or the required facilities to meet the demand are included in the proposed action, such as IT/COMM. The new GovGuam Layon Landfill was designed to accommodate the 2010 Final EIS proposed action, which would have a much higher solid waste generation rate. The demands on utilities are directly related to the proposed population growth and induced growth, which would be the same for all collective action alternatives. 2010 ROD-Related Actions contribute a less than significant impact to the collective action impact. The LFTRC would have very little direct or indirect impact on utilities. Significant mitigable impacts were identified for potable water and wastewater.

Potable water: Short-term significant localized impacts to potable water were identified in the NGLA based on a USGS groundwater model (USGS 2013). The impacts are potentially mitigable by DoD through enhanced water conservation measures, adjustment of pumping rates at DoD wells, and reduction in withdraws from the NGLA. In addition, DoD would continue to support the GWRDG. The long-term
impacts to potable water would be less than significant. Eleven additional DoD wells are included in the proposed action.

Wastewater: Significant mitigable impacts on wastewater were identified due to sewage treatment plants requirements to meet 2013 NPDES permits. Direct and indirect wastewater impacts from DoD and organic civilian population growth would be estimated to increase the wastewater flow to approximately 7.8 MGD (29.5 MLd). Performance, permit issues, and the timeframe to implement treatment system upgrades to meet 2013 NPDES permit requirements remains to be resolved for the Northern District WWTP, which is an issue independent of the proposed action. The Agaña WWTP would not receive direct DoD wastewater flows from the proposed action, but would be indirectly affected by the military relocation from wastewater flows from the indirect impacts from the imported construction workforce (during the construction phase only) and induced civilian growth. The estimated increased wastewater flow to the Agaña WWTP due to the proposed action only is 0.04 MGD (0.15 MLd). Similarly, the GWA southern WWTPs (Agat-Santa Rita WWTP, Baza Gardens WWTP, Umatac-Merizo WWTP, and Inarajan WWTP) would not receive direct DoD wastewater flows from the proposed action except for potential and minimal flow to Inarajan WWTP from LFTRC Alternatives 3 and 4 (as an optional but not recommended solution), but would be indirectly affected by the military relocation from indirect wastewater flows from the induced civilian growth as well as organic civilian growth in the region. The increased wastewater flow from indirect impacts from the proposed action to the four southern WWTPs is estimated to total 0.02 MGD (0.075 MLd). The Guam Legislature has recently authorized GWA to finance improvements to its wastewater systems in southern Guam.

Reasonably Foreseeable Actions that Affect Utilities. Three reasonably foreseeable future projects are anticipated to contribute to a cumulative effect to utilities on Guam (see Table 7.6-1). Two of these projects are utility improvement projects with potential beneficial impacts: the 60 MW Power Plant (G-6) and Umatac-Merizo STP Replacement (S-18). The future project that might induce growth or have other indirect impact on utilities include: Sigua Highlands (C-47).

Potential Cumulative Effects. There will be cumulative effects associated with the collective action alternatives and the actions of other federal agencies, local governments, and the private sector on utilities on Guam. Population increases are the cause of direct and indirect impact associated with the collective action alternatives. A few growth-inducing projects were identified from the recently completed, present, and reasonably foreseeable projects; however, there are pre-existing deficiencies that are being corrected, specifically for wastewater. The magnitude of the cumulative effect is moderate because the impacts are regional, the GovGuam building permit review process manages the number of new developments to prevent system failures, and deficiencies in utility service can be addressed by infrastructure improvements, subject to available funding (see Table 7.6-2).

Need for Mitigation. GovGuam has a number of infrastructure improvement projects to address existing deficiencies. Potential mitigation measures proposed for avoiding or reducing impacts to resources are listed in Tables 4.7-1 and 5.7-1. GovGuam reviews development proposals for utility capacity. No additional mitigation measures for cumulative effects are proposed.

7.7.15 Socioeconomics and General Services

Current Health and Historical Context. Guam’s socioeconomic attributes and general services are defined and discussed in detail in the 2010 Final EIS (Volume 2, Chapter 16: Socioeconomics and General Services, Section 16.1: Affected Environment, pages 16-1 to 16-67).
Guam’s population, as of the most recent full U.S. Census of 2010, was 159,358. The island’s population has grown significantly since becoming a U.S. Territory in 1950 - from a pre-war 1940 level of 22,900 (with a military and dependent population of 1,427) to 59,498 (with a military and dependent population of 26,617) in 1950. As of 2010, 42.5% of Guam’s population lived in households on the island’s northern region.

Between 1990 and 2000, the percentage representation of Chamorro and Caucasian ethnicities on Guam’s population declined, while Filipino and “Other” ethnicities (most often composed of other Asian or Pacific Islander ethnicities) increased. Guam’s ethnic makeup changed little from 2000 to 2010. In 2010, 42% of Guam residents were Chamorro or part Chamorro, 25% were Filipino, 8% were other Pacific Islanders, 7% were Caucasian, and 17% were of other races or ethnicities.

Guam’s economy has been volatile. The economy stagnated in the 1970s to early 1980s, partly due to the 1973 oil embargo. Tourism peaked between 1995 and 1997 but ended with the Japanese financial crisis in 1997. Super typhoon Pongsona as well as the September 11, 2001 terrorist attacks on the U.S. also affected the tourism market. From 2001 to 2003, Guam’s economy contracted. In 2005, tourism was the island’s second largest private industry and both the primary Japanese and secondary Korean markets were growing at that time. Many real estate developments were financed and constructed in anticipation of the military buildup as proposed in 2010. Guam’s real estate and tourism market slowed at the end of the decade, however, primarily due to the global economic decline and associated economic conditions. In addition, the reduced scope and longer timeframe associated with the 2012 Roadmap Adjustments (see Chapters 1 and 2 of this SEIS) led to a surplus of some housing types and a lower interest in future development.

Seventeen recently completed projects with the potential to contribute to a beneficial cumulative effect to socioeconomics and general services on Guam were identified (see Table 7.6-1). Many of these involved residential construction (e.g., Hemlani Apartments [C-34]) and other projects that provide a public good, such as the Veterans Clinic (C-3).

Nineteen present projects with the potential to contribute to a beneficial cumulative effect to socioeconomic conditions and general services on Guam were identified (see Table 7.6-1). Many of these involve residential construction ranging from worker and low-income housing (e.g., Sagan Bonita [C-26]) to luxury (e.g., C-21) and multi-unit buildings (e.g., Paradise Meadows [N-36]). Others involve commercial development (N-29), and medical facilities (e.g., G-7).

**Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect.** As summarized in Tables 7.4-1 and 7.6-2, there would be significant impacts related to an anticipated greater than 2% population growth and the anticipated strain on public service staffing under all collective action alternatives. The significant impacts to public services would be mitigable. Less than significant impacts on economic activity and sociocultural issues were identified for all alternatives. Beneficial impacts could include increased employment and standards of living, and some increase in construction-related business travel. The type and magnitude of the impacts are population dependent and similar for all collective action alternatives. No additive (Section 6.1) or 2010 ROD-Related Action (Section 6.2) impact on socioeconomics and general services was identified.

**Reasonably Foreseeable Actions that Affect Socioeconomics and General Services.** Four reasonably foreseeable future projects are anticipated to contribute to a beneficial cumulative effect to socioeconomic conditions and general services on Guam (see Table 7.6-1), including the Territorial Prison (G-10) and a 60-MW Power Plant (G-6).
**Potential Cumulative Effects.** Assessing the potential cumulative effects related to socioeconomics and general services is complicated by the inherent balance of adverse and beneficial impacts for each of the criteria: population change, economic activity, public service, sociocultural, and land acquisition (sociocultural and economic). The socioeconomic impacts are potentially Guam-wide. There are no regulatory thresholds that dictate the economic or sociocultural health; however, there are recognized stressors or threats, such as influx of immigrant populations, ex-migration of a significant employer, land acquisition by the federal government, and decreases in tourism. In general, these adverse impacts are reversible over time. The sociocultural adverse impacts of projects are more difficult to address, but very few of the recently completed, present or reasonably foreseeable projects would have a sociocultural impact. The sociocultural impact of the collective action alternatives is limited to land acquisition (less than significant) and the influx of population (significant). For these reasons, the cumulative effects of the collective action alternatives in conjunction with the recently completed, present, and reasonably foreseeable projects is moderate (see Table 7.6-2).

**Need for Mitigation.** Potential mitigation measures proposed for avoiding or reducing impacts to resources are listed in Tables 4.7-1 and 5.7-1. No additional mitigation measures for cumulative effects are proposed.

### 7.7.16 Hazardous Materials and Waste

**Current Health and Historical Context.** As summarized in Chapters 3, 4, and 5 of this SEIS, and in the 2010 Final EIS, hazardous material, toxic substance, and hazardous waste handling are collectively referred to as hazardous substances. WWII established a high baseline of environmental releases; but overall, the trend in hazardous substance use is associated with increases in population and industrial activity. During the 1970s, there were numerous local and federal environmental regulations enacted to protect human health and the environment and to closely control and regulate the transport, storage, use, and disposal of hazardous substances. While the trend in use of hazardous substances is expected to increase over time, regulations currently in place minimize the risk of release to the environment as well as the risk to human health. This trend would continue at a more gradual rate of increase. Since the 2010 Final EIS there have been no substantive changes to the quantity of hazardous materials and waste Guam-wide as there has been no increase in the number of regulated facilities (USEPA 2013). Additionally, there have been no substantive changes to law, regulations or policies pertaining to the management of hazardous materials and waste (Section 3.16.2). The impacts are largely related to human activities, but natural events such as typhoons and earthquakes can result in inadvertent releases of regulated hazardous substances.

Twelve recently completed projects have the potential to contribute to hazardous materials and waste cumulative effects on Guam (see Table 7.6-1). Nine of these could contribute adversely, whereas three could be beneficial such as replacement of the Gas Cylinder Storage Facility (C-7) and the Naval Hospital (C-8). The beneficial impacts are based on the presumption that newer, more efficient facilities could potentially use less hazardous materials and produce less hazardous waste. A new industry or industrial facility has potential to adversely impact hazardous materials because they could increase the on-island management of hazardous materials and waste, such as MIRC EIS/OEIS (G-2) and Kilo Wharf Extension (AH-4).

Eleven present projects have potential to contribute to cumulative hazardous material impact (see Table 7.6-1). Five of these could contribute adversely by increasing the amount of materials and waste on island, such as Fuel System Maintenance Hangar (N-51). However, six projects could have a beneficial impact on potential cumulative effects, including POL System Hardened Structures (N-47), General
Purpose Hangar (N-52), PRTC SF Fire Rescue Emergency Management (N-50), and Upgrade JP-8 Receipt Pipeline (C-44) by increasing capacity or repairing existing infrastructure that is associated with the management of hazardous materials and waste.

Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect. As summarized in Tables 7.4-1 and 7.6-2, the collective action alternatives would result in less than significant impacts to hazardous materials management, hazardous waste management, existing contaminated sites and toxic substances. The impacts would be the same for all of the alternatives. The impacts would be associated with an increase in the management of hazardous materials and waste managed. The impacts would be less than significant because the transportation, storage, handling, use, and disposal of these substances is heavily documented, controlled, and regulated at the federal and local level in a “cradle to grave” comprehensive manner. The potential for radon intrusion in new construction would be addressed in facility design. Existing contaminated sites were identified at the NWF LFTRC and these would be avoided to the extent practicable for a less than significant impact.

Reasonably Foreseeable Actions that Affect Hazardous Materials and Wastes. Two reasonably foreseeable projects could contribute to hazardous substances and waste cumulative effects. These projects include the 60 MW Power Plant (G-6).

Potential Cumulative Effects. There will be cumulative effects associated with the collective action alternatives and the actions of other federal agencies, local governments, and the private sector on hazardous materials on Guam. The degree of cumulative effect resulting from the collective action alternatives is considered to be low (see Table 7.6-2) because the existing environmental laws and regulations and associated BMPs and SOPs require that hazardous substances are handled, used, and disposed of in a comprehensive “cradle to grave” manner that inherently reduces the overall risk to human health and the environment. This projection is based on the assumption that existing hazardous materials, toxic substances, and hazardous waste transportation, handling, storage, use, and disposal procedures and protocols are properly implemented and modified as appropriate to address the increased hazardous substances demand. Most of the recently completed, present, and reasonably foreseeable future projects would increase the management and capacity to handle regulated hazardous substances on Guam. However, these impacts would not contribute appreciably to the increasing trend in the volume of regulated hazardous substances already being handled and managed on Guam.

Need for Mitigation. Potential mitigation measures proposed for avoiding or reducing impacts to resources are listed in Tables 4.7-1 and 5.7-1. GovGuam reviews development proposals for proper use and management of hazardous materials. No additional mitigation measures for cumulative effects are proposed.

7.7.17 Public Health and Safety

Current Health and Historical Context. As summarized in Sections 3.17, 4.2.17, 5.5.17, and in detail in the 2010 Final EIS (Volume 2, Section 18.1: Affected Environment, pages 18-1 to 18-12), the historical trends in public health and safety are difficult to determine. WWII is the most damaging recent event on Guam’s history impacting human health and safety. The trends in public health and safety are a function of changes in population and operations, or industries that involve dangerous materials (e.g., hazardous substances, live ammunition, electromagnetic energy, radiological substances). The socioeconomics section describes changes in population over time. From 1970 to 2000, the population on Guam increased, but declined in subsequent years. The number of occupational and traffic accidents has
increased gradually over the years. The trend in notifiable diseases is increasing gradually, but is related to population. The increase in construction and ground-disturbing activities would increase the risk of uncovering UXO; live ammunition is largely a military activity and changes with the military mission. Guam health and public services (i.e., lack of skilled professionals and lack of up-to-date equipment) are sub-standard due to lack of funding; this trend is likely to continue in the absence of economic development.

Thirty-nine recently completed projects were identified that could result in cumulative public health and safety impacts. Thirty-six would likely have a beneficial impact because they would improve traffic safety (e.g., S-1) or health services (e.g., C-3).

Fifty-seven present projects were identified that could result in cumulative public health and safety impacts. Fifty-two projects may be beneficial because they involve road improvements (e.g., Route 1-8 Intersection Improvements & Agaña Bridges Replacement[C-29]), utility improvements (e.g., S-8), or health care improvements (e.g., N-38). Some military development projects (e.g., N-48, N-39) would have an adverse impact because they could contribute to the perception of Guam becoming a terrorist target.

**Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effects.** As summarized in Tables 7.4-1 and 7.6-2, the collective action alternatives would result in less than significant impacts to public health and safety on Guam for the following categories:

- Healthcare services (notifiable diseases/mental illness)
- Operational safety
- Environmental health (water quality, hazardous substances)
- Traffic incidents

Significant impacts were identified for the collective action alternatives that include cantonment at AAFB (Alternatives C-1, C-2, C-3, C-4, and C-5). During operations, in the event of a munitions transport incident or explosives incident at the North Gate, a significant direct impact related to explosive safety could occur. A less than significant impact was identified for all other collective action alternatives.

**Reasonably Foreseeable Actions that Affect Public Health and Safety.** Sixteen reasonably foreseeable projects are anticipated to contribute to a cumulative public health and safety impact, 14 of which may have beneficial impacts, such as the Territorial Prison (G-10).

**Potential Cumulative Effects.** Anticipated impacts to public health and safety would have a cumulative effect when combined with recently completed, present, and reasonably foreseeable actions on Guam identified above. The impact is not quantifiable. There are no regulatory thresholds for public health and safety. The degree of additive impact resulting from the collective action alternatives would be considered to be moderate (see Table 7.6-2) because the cumulative effect is based largely on population increases and available resources, and is island-wide.

**Need for Mitigation.** Potential mitigation measures proposed for avoiding or reducing impacts to resources are listed in Tables 4.7-1 and 5.7-1. GovGuam reviews development proposals and advocates for public health and safety. No additional mitigation measures for cumulative effects are proposed.

### 7.7.18 Environmental Justice and the Protection of Children

**Current Status and Historical Context.** As summarized in Chapters 3, 4, and 5 of this SEIS, and in the 2010 Final EIS (Volume 2, Section 19.1: Affected Environment, pages 19-1 to 19-8), Environmental Justice is an important concept that was introduced in 1994 by EO 12898. It applies to federal actions.
Guam has a higher percentage of racial minorities, low-income populations, and children, when compared with the continental U.S. Much of the island’s population would likely continue to struggle with poverty and access to basic community services, especially when the social and health services are inadequate for the existing population. The existing inadequate roads and utilities would likely continue to deteriorate, having an adverse and disproportionate impact on disadvantaged residents of Guam. It is noted that the collective action alternatives would improve various roads and highways affected by the collective action alternatives.

Forty-three of 46 recently completed projects could contribute to a beneficial environmental justice and protection of children impact on Guam, including Road Safety Improvements (G-1), housing projects such as Paradise Estates (N-2) and Lada Estates (N-31), and public infrastructure projects, such as Layon Landfill (S-3) (see Table 7.6-1).

Sixty-three of 66 present projects could beneficially contribute to environmental justice and protection of children on Guam (see Table 7.6-1). The beneficial projects include residential construction, particularly for low-income housing (e.g., Sagan Bonita [C-26]), a Health Clinic (G-7), and Guam Regional Medical City (N-38). Potential adverse impacts are associated with increases in island population, such as the Pacific Airpower Resiliency (N-26).

Direct and Indirect Impacts of the Collective Action Alternatives that might Contribute to a Cumulative Effect. As summarized in Tables 7.4-1 and 7.6-2, significant impacts were identified for all collective action alternatives. The significant impact is associated with (1) the greater than 2% increase of on-island population that would have an impact on existing public safety staffing levels, and (2) disproportionate socioeconomic impacts on low-income populations. The type and magnitude of the impacts would be similar under each of the collective action alternatives. Less than significant impacts to environmental justice populations were identified operational safety and noise levels, and recreation for all collective action alternatives. Land acquisition would have a less than significant impact on environmental justice populations, except for alternatives that include a LFTRC at AAFB NWF (i.e., A-5, B-5, C-5, D-5, E-5), in which case there is no land acquisition proposed. No additive impacts (Section 6.1) were identified. Less than significant impacts construction phase impacts related to health care service were identified for the 2010 ROD-Related Action (Section 6.2).

Reasonably Foreseeable Actions that Affect Environmental Justice and the Protection of Children. Fifteen reasonably foreseeable projects are anticipated to contribute to a cumulative impact, none of which would like have an adverse impact. Infrastructure improvement projects (e.g., Route 26/25 Intersection Improvements) and public service infrastructure (e.g., Territorial Prison G-10) would likely have a beneficial cumulative effect.

Potential Cumulative Effects. There will be cumulative effects associated with the collective action alternatives and the actions of other federal agencies, local governments, and the private sector on environmental justice and the protection of children on Guam. There are no specific thresholds to measure the cumulative effects of all the projects being considered. The degree of additive impact resulting from the collective action alternatives would be considered to be strong (see Table 7.6-2) because the current status of the population is not resilient to additional stress and the impacts are island-wide.

Need for Mitigation. Potential mitigation measures proposed for avoiding or reducing impacts to resources are listed in Tables 4.7-1 and 5.7-1. No additional mitigation measures for cumulative effects are proposed.
7.8 CLIMATE CHANGE AND GLOBAL WARMING

This section is largely as presented in the 2010 Final EIS (Volume 7, Chapter 4: Cumulative Effects, Section 4.4: Climate Change and Global Warming, pages 4-87 to 4-94) but was updated with new information. The effect of greenhouse gases on climate change and global warming from the collective action alternatives and the associated regulatory framework remain the same as detailed in the 2010 Final EIS.

The 2010 Final EIS-predicted construction and operational greenhouse gas described in terms of total annual emissions from island-wide activities. As indicated by the air quality modeling results presented in Sections 4.1.3, 5.1.3, and 6.1 of this SEIS, and because of the overall reduced scale of construction and population change for the Marine Corps relocation under the 2012 Roadmap Adjustments, the operational greenhouse gas emissions for the SEIS proposed action would be lower than those analyzed in the 2010 Final EIS. Therefore, cumulative air quality impacts in terms of proposed construction and facility operations associated with this SEIS would be less than those described in the 2010 Final EIS.

The collective action alternatives discussed in this SEIS are unlikely to vary substantially in the quantity of CO₂-e emissions. For example, the same amount of construction activities would occur regardless of the different locations (alternatives), resulting in essentially the same amount of greenhouse gas emissions. Therefore, the greenhouse gas emissions for the different alternatives would be similar to those of the collective action alternatives.

The change in climate conditions caused by greenhouse gas resulting from the burning of fossil fuels from the proposed alternatives is a global effect, and requires that the emissions be assessed on a global scale. The collective action alternatives mainly involve the relocation of the military operations that are already occurring in the West Pacific region; therefore, fossil fuel burning activities in the West Pacific region are unlikely to change significantly. Consequently, overall global greenhouse gas emissions are unlikely to change on a regional or global scale as a result of the collective action alternatives, resulting in an insignificant cumulative effect to global climate change. No potential specific greenhouse gas emission mitigation measures are proposed.

7.8.1 Climate Change Adaptation

Climate change is a global issue for DoD. As is outlined in the Quadrennial Defense Review of February 2010, DoD needs to adjust to the impacts of climate change in military facilities and military capabilities. The DoD already provides environmental stewardship at hundreds of DoD installations throughout the U.S. and around the world, working diligently to meet resource efficiency and sustainability goals as set by relevant laws and executive orders. Although the U.S. has significant capacity to adapt to climate change, it will pose challenges for civil society and DoD alike, particularly in light of the nation’s extensive coastal infrastructure. In 2008, the National Intelligence Council judged that more than 30 U.S. military installations were already facing elevated levels of risk from rising sea levels. DoD’s operational readiness hinges on continued access to land, air, and sea training and test space. Consequently, the DoD must complete a comprehensive assessment of all installations to assess the potential impacts of climate change on its missions and adapt as required.

The Quadrennial Defense Review goes on to illustrate that DoD will work to foster efforts to assess, adapt to, and mitigate the impacts of climate change. Domestically, the Department will leverage the Strategic Environmental Research and Development Program, a joint effort among DoD, the Department of Energy, and the USEPA, to develop climate change assessment tools. Abroad, the Department will increase its investment in the Defense Environmental International Cooperation
Program not only to promote cooperation on environmental security issues, but also to augment international adaptation efforts. The DON operational side published the *Task Force Climate Change Roadmap* on May 21, 2010, which builds off the Quadrennial Defense Review and focuses on the naval operational challenges of a changing climate. Although the document does not address compliance issues, the roadmap also recognizes the need to address sea level rise impacts on infrastructure and real estate through strategic investments and installation adaptation strategies to address water resource challenges.

Guam would have some unique adaptation issues to evaluate and consider. The U.S. Global Climate Research Program report, “Global Climate Change Impacts in the U.S.” reviewed the unique impacts of Climate Change on Islands. According to the report, climate change presents U.S.-affiliated islands with unique challenges. Small and low elevation islands are vulnerable to sea-level rise, coastal erosion, extreme weather events, coral reef bleaching, ocean acidification, and contamination of freshwater resources with saltwater. The islands have experienced rising temperatures and sea level in recent decades. Projections for the rest of this century suggest continued increases in air and ocean surface temperatures in both the Pacific and Caribbean, an overall decrease in rainfall in the Caribbean, an increased frequency of heavy downpours nearly everywhere, and increased rainfall during the summer months (rather than the normal rainy season in the winter months) for the Pacific islands. Hurricane wind speeds and rainfall rates are likely to increase with continued warming. Island coasts would be at increased risk of inundation due to sea-level rise and storm surge with major implications for coastal communities, infrastructure, natural habitats, and resources.

### 7.8.1.1 Climate Change and Impacts on Waterfront Facilities

Until 1900, there was little change in sea level, but during the last century, sea level rose gradually and is currently rising at an increased rate. The average rate of sea level rise measured by tide gauges from 1961 to 2003 was 0.071 ± 0.02 inches (0.18 ± 0.05 cm) per year, with an annual increase of 0.12 ± 0.03 inch (0.31 ± 0.07 cm) seen between 1993 and 2003, and a total increase of 6.7 ± 2 inches (17 ± 5 cm) during the 20th century. This increase is due to thermal expansion (indicating increased heat content) and the exchange of water between oceans and other reservoirs (i.e., glaciers and ice). By the end of this century, sea level is predicted to rise 7-23 inches (18-59 cm), with an additional 4-8 inches (10-20 cm) rise possible due to the melting of land ice sheets in Greenland (Intergovernmental Panel on Climate Change 2007).

Projections made for Guam indicate that sea level rises of up to 39 inches (100 cm) would result in a few low lying areas of Apra Harbor being inundated. The DON acknowledges there is the potential for existing and future coastal facilities to be adversely affected by sea level rise, inundations from more extreme storm events, and other consequences of climate change. However, predictive models on future sea level rise are subject to variability, due in part to unknown future greenhouse gas emissions. The variability increases with the period of time being assessed. Risk assessment methodologies and technologies are being developed to predict the potential impacts of climate change on existing DON coastal facilities. As new design criteria relevant to climate change are adopted by the DON, they will be incorporated into project designs. Harbor projects on Guam are designed to include tsunami, typhoon, wind, and earthquake conditions.

The waterfront activities of the collective action alternatives are limited to the wharf improvements at Inner Apra Harbor. These improvements include repair and maintenance of existing wharves and construction of support facilities. The Inner Apra Harbor wharf improvements do not alter the original
wharf design; the elevations are not altered. As new design criteria are adopted by the DON, they will be incorporated into programmed projects.

7.8.1.2 Climate Change and Impacts on Aquifers

The availability of freshwater is likely to be reduced, with significant implications for island communities, economies, and resources. Most island communities in the Pacific and Caribbean have limited sources of freshwater. Many islands depend on surface water and freshwater lenses below the surface, which are recharged by precipitation. Changes in precipitation, like the anticipated increases in summer precipitation and the frequency of heavy rains, would increase on Guam. This would increase the potential to cause more frequent flooding, which could compromise the quality of water supplies. Sea-level rise also affects island water supplies by causing salt water to contaminate the freshwater lens and by causing an increased frequency of flooding due to storm high tides. Water pollution (such as from agriculture or sewage), exacerbated by storms and floods, can contaminate freshwater supplies, affecting public health.

The collective action alternatives, specifically the additional population, could have an additive cumulative effect with climate change impacts on aquifer yield. However, the USGS and WERI have recently developed a groundwater model for Guam that can be used to assist with the management of groundwater production from the NGLA (USGS 2013). The development of this groundwater model included consideration of different climate scenarios, including extended drought. The groundwater model will be used by the GWA and DoD and serve as a tool to assist in estimating the impacts of selected groundwater-pumping and climate scenarios on the water supply.

In addition, the USGS was recently awarded a study under a Strategic Environmental Research and Development Program grant from DoD. The 4-year study Water Resources on Guam: Potential impacts and adaptive response to climate change for DoD Installations would evaluate potential adverse climate-change impacts on DoD installations that rely on Guam’s surface water and groundwater resources and identify the adaptive capacity to minimize the adverse impacts. Potable water demands are projected to increase and the effects of climate change may limit the water resources available to meet these demands. The study will address potential impacts of and adaptations to climate change with the following: (1) evaluation of the accuracy of the Coupled Model Intercomparison Project Phase 5 results and use of the best Coupled Model Intercomparison Project Phase 5 models to generate downscaled climate projections and to quantify changes in tropical cyclone activity; (2) update and expansion of an existing watershed model for southern Guam to evaluate climate driven changes in streamflow captured by Fena Valley Reservoir; (3) analysis of climate change induced modifications in sediment loads and turbidity of water entering Fena Valley Reservoir; (4) refinement of the hydrologic budget of northern Guam to estimate groundwater recharge for current and future conditions; (5) update of the existing numerical groundwater model to incorporate these recharge changes; and (6) establishment of rigorous stakeholder participation. The climate change driven impacts to existing infrastructure and the adaptive capacity to minimize the impacts will be evaluated by (1) showing temporal changes in surface water reservoir storage for climate change scenarios due to modified streamflow, estimating reduced (due to sedimentation) or increased (due to dredging or raised spillway) reservoir storage capacity, and estimating the frequency and volume of high-turbidity events; (2) quantifying changes in groundwater salinity from new recharge and sea-level estimates, and testing adaptive pumping and well design strategies for a range of climate scenarios and projected demand estimates; and (3) investigating the conjunctive use of surface water and groundwater to maximize DoD’s potential for developing water resources.
7.8.1.3 Climate Change and Impacts on Coral Reefs

Climate change and ocean acidification have been identified as the greatest global threats to coral reefs, resulting in mass coral bleaching events, reduced coral growth rates, and potential increases in the frequency and severity of coral disease outbreaks. Coral are particularly sensitive to the impacts of climate change as even small increases in water temperature can cause coral bleaching. As concentrations of atmospheric CO₂ increase, more CO₂ is absorbed at the surface of water bodies. Elevated CO₂ concentrations are resulting in ocean acidification, which changes the chemistry of ocean water, including a decrease in the saturation state of calcium carbonate. Marine calcifiers, such as corals, use calcium carbonate to form shells, skeletons, and other protective structures and reduced availability of it can slow or even halt calcification rates in these organisms.

The collective action alternatives on Guam would increase the levels CO₂ generated on Guam (see Table 7.6-1) and contribute to the climate change impacts on the future health of corals and other marine resources on Guam. In addition to dredging (for the 2010 ROD-Related Actions), there are other potential impacts to marine resources associated with the collective action alternatives (i.e., increased marine recreational use) that would contribute to the cumulative effect; however, potential mitigation measures such as awareness training could offset these impacts to some degree.

7.8.1.4 Conclusions

The collective action alternatives would contribute to climate change. As climate science advances, the DON would regularly reevaluate climate change risks and develop policies and plans to manage any climate change impacts to DON’s operating environment, missions, and facilities. As indicated in Section 7.8.1.2 in this SEIS, a 4-year study is being done that would evaluate potential adverse climate-change impacts on DoD installations that rely on Guam’s surface water and groundwater resources and identify the adaptive capacity to minimize the adverse impacts. Managing the impacts of climate change on national security would require the DON to work collaboratively, through a whole-of-government approach with GovGuam.
CHAPTER 8
ADDITIONAL CONSIDERATIONS REQUIRED BY NEPA

8.1 INTRODUCTION

This chapter addresses additional considerations required by NEPA, which includes consistency with other federal, state, and local land use plans, policies, and controls; required permits and approvals; irreversible and irretrievable commitment of resources; the relationship between short-term use of the environment and long-term productivity; and sustainability and smart growth.

8.2 CONSISTENCY WITH OTHER FEDERAL, STATE, AND LOCAL LAND USE PLANS, POLICIES, AND CONTROLS

The proposed action alternatives as outlined in this SEIS have been developed to ensure consistency with land use guidelines for the project areas and with the objectives of federal, regional, state, and local land use plans, policies, and controls. The DON does not have zoning laws or codes, but there are ideal functional relationships among land uses that guide installation development. Naval Base Guam and AAFB have land use plans that currently guide land use planning for those installations. The Regional Commander, in consultation with base planners, would direct future development to be consistent with the objectives of the land use plan. Other relevant planning documents that would affect future development include Regional Shore Infrastructure Plans and UFC documents that provide planning, design, construction, sustainment, restoration, and modernization criteria. The proposed action alternatives discussed in this SEIS would follow these guidelines. In addition, these alternatives have been developed in consultation with base planners and approved by the Regional Commander; therefore, all of the proposed action components would also be in compliance with COMNAV Marianas Instruction 3500.4, Marianas Training Handbook (DoD 2000) and MCO P3550.10 (DON 2005).

AAFB identified a number of land use compatibility issues associated with the proposed NWF LFTRC; these are summarized in Table 8.2-1. The Army National Guard also identified potential impacts associated with Alternative D (cantonment and family housing at Barrigada) to include: delays in their ongoing processes to acquire additional acreage north or east of the existing Army National Guard compound; a potential reduction in access to training areas that the Army National Guard currently uses in the Barrigada area; and a potential for increased traffic impacts associated with the Army National Guard’s plans for future development near their main entrance. The Territory of Guam Master Plan that was prepared for the Territorial Planning Commission in 1966 is the adopted land use plan for Guam. Other plans have been developed such as the 1978 Guam Comprehensive Development Plan (Bureau of Plan 1978) and 1994 I Tano’-ta: The Land Use Plan for Guam (Territorial Planning Council 1994). The 1978 Plan was valid for a planning period up to 2000. The I Tano’-ta was adopted in the Guam Land Use and Zoning Law in 1999, but subsequently suspended and the 1966 zoning and zoning law is the prevailing regulation (Bureau of Statistics and Plans 2008). These plans provide valuable information on existing and planned land uses at points in time. The Bureau of Statistics and Plans recently prepared the North and Central Guam Land Use Plan. Although the plan was adopted, the associated changes to zoning codes are pending. The assumption is that the land use plan represents the general direction of GovGuam and the community with respect to guiding future land use development in the central and northern areas of Guam. There are no such plans for the southern portion of Guam. It is also likely that rezoning of property in the surrounding community would occur in response to DoD development. The
North and Central Plan guides development decisions generally but refinement or more precise expression of land use occurs through Guam Land Use Commission actions that may or may not follow the general plan. The DoD has no direct control or authority over this process except to attempt to mitigate effects of incompatible land uses near installations. Additionally, the DoD assists communities to plan for “outside the fence” land use and economic impact through the OEA.

### 8.3 REQUIRED PERMITS AND APPROVALS

A list of federal and local permits that may be required for implementation of any of the alternatives is provided in Table 3.1-1 of the 2010 Final EIS (Volume 8, Chapter 3: Required Permits and Approvals, pages 3-1 through 3-5). Permits and approvals for the proposed action are expected to be the same as for the 2010 Final EIS for the NEPA EIS review as well as project design, construction, and operation phases. While some regulations require permits, many serve only as guidance. DoD-proposed actions would be implemented in accordance with all applicable regulatory mandates.

Federal regulations that are or may be applicable to the proposed action include, but are not limited to:

- Archeological and Historic Resources Preservation Act
- ARPA
- CAA
- CWA
- Coastal Zone Management Act
- Comprehensive Environmental Response, Compensation, and Liability Act
- Department of Transportation Regulations
- National Wildlife Refuge System Administration Act
- Migratory Bird Treaty Act
- NHPA
- Noise Control Act
- Oil Pollution Act
- OSHA
- Pollution Prevention Act
- Resource Conservation and Recovery Act
Guam regulations that are or may be applicable to the proposed action include, but are not limited to:

- Guam Coastal Nonpoint Pollution Control Program
- Guam Air Pollution Control Standards and Regulations
- Guam Environmental Protection Act
- Guam Hazardous Waste Management Program
- Guam Primary Drinking Water Regulations
- Guam Seashore Protection Act and Permit System
- Guam Soil Erosion and Sedimentation Control Regulations/Permits
- Guam Water Quality Standards
- Test Boring and Dewatering Permit
- Guam CWA Section 401 Water Quality Certification
- Guam Water Resources Development and Operating Regulations

8.4 **Irreversible and Irretrievable Commitment of Resources**

NEPA § 1012(c)(iv) requires a detailed statement on any irreversible and irretrievable commitments of resources that would be involved in the proposed action should it be implemented. Irreversible and irretrievable resource commitments are related to the use of non-renewable resources and the effects that the use of those resources have on future generations. Irreversible commitments of resources are those that cannot be reversed except over an extremely long period of time. These irreversible effects primarily result from destruction of a specific resource (e.g., energy and minerals) that cannot be replaced within a reasonable timeframe. Irretrievable resource commitments involve the loss in value of an affected resource that cannot be restored as a result of the action (e.g., extinction of a threatened or endangered species or the disturbance of a cultural site).

The proposed action would constitute an irreversible or irretrievable commitment of non-renewable or depletable resources, for the materials, time, money, and energy expended during activities required for implementing the proposed action. Irreversible and irretrievable commitments of resources would occur under all alternatives. Particular irreversible and/or irretrievable impacts that would result are noted below. These impacts are similar to those described in the 2010 Final EIS (Volume 8, Chapter 4, Irreversible and Irretrievable Commitment of Resources, pages 4-1 through 4-2).
Irreversible and irretrievable commitment of resources related to the construction and operation of the proposed cantonment/family housing includes consumption of fossil fuels and energy for construction equipment, materials for construction of new facilities and associated private-sector economic and population growth, and physically altering land with construction and committing land associated with the project to a new use for the foreseeable future. Construction and operation of the proposed LFTRC would result in an irreversible and irretrievable commitment of fossil fuels and materials as well as a commitment of land and airspace for training activities associated with LFTRC operations.

Materials and energy consumed for the project represents a permanent and non-renewable commitment of these resources. Construction and maintenance activities are considered a long-term, non-renewable investment of these resources. Land that would be physically altered by construction would be committed to the new use for the foreseeable future, and would represent a permanent commitment of the land for the life of the project to a developed use, decreasing the amount of open land available for other uses. Access to the developed lands would be limited to authorized personnel.

Compared to the 2010 Final EIS, the proposed action addressed in this SEIS comprises a smaller Marine Corps cantonment/family housing area, a similarly-sized LFTRC that has a smaller SDZ footprint (based on the SDZ reduction achieved by applying the probabilistic methodology to the MPMG range), and reduced-scale infrastructure requirements to support a reduced number of relocating Marines and dependents than originally planned. Therefore, there would be a reduction in the irreversible and irretrievable commitment of resources based on the proposed action described in this SEIS compared to the 2010 Final EIS, primarily with respect to the cantonment/family housing area and reduced-scale infrastructure requirements.

Under the No-Action Alternative, the DON would implement projects identified in the September 2010 ROD (see Section 2.1 of this SEIS). The decision to construct and operate the LFTRC would remain deferred, and the DON would establish a cantonment/family housing area for approximately 8,600 Marines and 9,000 dependents on federally controlled lands at Finegayan and South Finegayan and by acquiring land known as the former FAA parcel. Therefore, under the No-Action Alternative there would also be irreversible and irretrievable commitments of resources. Irreversible and irretrievable commitments of resources as described in the 2010 Final EIS (Volume 8, Chapter 4: Irreversible and Irretrievable Commitment of Resources, pages 4-1 through 4-2) would be the same, although there would be slightly less commitment of land resources and consumption of fossil fuels and energy for construction and operation of the LFTRC.

8.5 **Relationship Between Short-Term Use of the Environment and Long-Term Productivity**

Section 102(2)(C)(iv) of NEPA requires an analysis of the relationship between a project’s short-term impacts on the environment and of the effects that these impacts may have on the maintenance and enhancement of the long-term productivity of the affected environment (i.e., ability to obtain or generate desired goods, services, or benefits in the future). Impacts that narrow the range of beneficial uses of the environment are of particular concern. This refers to the possibility that choosing one development option reduces future flexibility in pursuing other options, or that designating a parcel of land or other resource for a certain use eliminates the possibility of other uses being performed at the site.

Short-term uses of the environment associated with the proposed action include changes to the physical environment and energy and utility use during the construction of facilities associated with all alternatives. Construction would involve short-term increases in fugitive emissions and construction-
generated noise and would increase the use of fossil fuels to provide power to equipment. In addition, expenditures of public funds and the use of labor would be required.

Long-term changes would include alterations to land use on Guam that would exist for the life of the new facilities. For the purposes of this section, the “lifespan” of the proposed action is undefined but would end whenever the use of the proposed cantonment, LFTRC, and/or family housing areas are no longer needed by the DoD.

There are numerous BMPs, plans, procedures, protocols, regulations, and laws that have been established to protect human health and the environment. Compliance with regulatory mandates, permit conditions and protective measures by the DoD and its contractors would reduce both short-term and long-term impacts. In addition, by minimizing these impacts, the relationship between short-term use of the environment and long-term productivity would not be adversely affected because the range of options for future beneficial uses would not be diminished, allowing for more flexibility in long-term use options.

8.5.1 Geological and Soil Resources

Construction of the proposed action would require cut and fill, grading and contouring with long-term changes to topography. These alterations would persist beyond the life of the project. Future land uses could restore the topography - if warranted.

There would be a larger area of the island where soil is disturbed from its natural condition and identified as Urban Land Complex due to the proposed action. Slope stability would not be altered. Engineering controls implemented during project design and construction, as well as stormwater control measures implemented during operations, would control drainage and runoff and minimize the risk of soil erosion. The potential for erosion due to live-fire range activities would be minimized through range maintenance and management activities.

For any sinkholes discovered before or during construction, BMPs would include compliance with the requirements of 22 GAR Chapter 10 § 10106F; therefore, the proposed action would not result in significant impacts to sinkholes. The proposed action would not increase the risk associated with earthquakes, fault rupture, slope instability, tsunamis and liquefaction.

Use of geology and soils for implementation of the proposed action would not reduce the range of options for future beneficial uses and less than significant impacts to long-term productivity are expected.

8.5.2 Water Resources

There would be an increase in the amount of impervious surface resulting from implementation of the proposed action. With the application of BMPs, LID, sustainable measures, and compliance with federal and GovGuam guidelines, water quality on Guam would be protected from impacts resulting from the proposed action. Long-term beneficial impacts to nearshore water quality would occur through mitigation by assisting the GWA in identifying funding from federal agencies to upgrade the Northern District WWTP.

The potential for leachate from MECs affecting surface water or groundwater would be minimized through range maintenance BMPs and management activities.

The proposed action would not increase the risk of flood hazards and would result in either no impacts to wetlands or less than significant impacts to wetlands through mitigation, depending upon the alternatives selected.
The proposed action would not reduce the range of options for future beneficial uses and less than significant impacts to long-term productivity are expected.

8.5.3 Air Quality

Construction and operational air quality impacts associated with the proposed action would not exceed significance thresholds.

Administration, maintenance, housing, and quality of life operations would receive power from existing stationary utility sources and include installations of various emergency generators on Navy and other critical DoD/Marine Corps facilities. However, the affected existing stationary utility sources would be operated below their currently permitted capacity under the proposed action. Therefore, operating these affected existing power sources would be in compliance with the applicable NAAQS, resulting in a less than significant impact. For anticipated installations of emergency generators at critical DoD facilities, if required under the CAA and/or GEPA permit regulations, applicable existing facility air permits would be modified or new air permits would be obtained at new facilities during the design phase of the project. This would ensure that these new emergency generators would be operated in compliance with applicable air regulations, resulting in a less than significant impact.

Stationary source air emissions due to the proposed action are not expected to violate air quality regulations designed to protect human health and the environment, and therefore would not degrade the long-term productivity of the ambient air environment. The proposed action would not reduce the range of options for future beneficial uses and less than significant impacts to long-term productivity are expected.

8.5.4 Noise

Construction and operational noise impacts associated with the proposed action would not exceed impact assessment criteria thresholds. There are no sensitive receptors that would be within the Zone II contour for the LFTRC. The steady-state noise generating activities at Finegayan would be primarily due to traffic and the impact would be less than significant.

Noise generated by the proposed action would cease at the end of the life of the project with no long-term impacts on ambient noise levels. The proposed action would not reduce the range of options for future beneficial uses and less than significant impacts to long-term productivity are expected.

8.5.5 Airspace

The proposed action, specifically the LFTRC, would have the potential for significant impacts to aviation. The potential impacts associated with the proposed action would be further studied through the DON, Air Force, and FAA consultation process and measures would be identified through this consultation process to minimize the potential effects. In addition, impacts to airspace generated by the operation of the proposed action would not permanently alter the airspace. FAA could revisit relevant airspace parameters and designations and restore the airspace to existing conditions at the end of the life of the proposed action. The proposed action would not reduce the range of options for future beneficial uses and less than significant impacts to long-term productivity are expected.

8.5.6 Land and Submerged Land Use

There are federal and GovGuam submerged lands that would be impacted by the LFTRC SDZs. The LFTRCs would result in new public access restrictions for health and safety reasons. At the end of the
The proposed action would change the current land uses of existing federal lands, and prior to implementation of the proposed action, any on-base land use compatibility issues will have been resolved. NWR land, currently managed by USFWS for conservation and education, would be within the LFTRC SDZs. USFWS administrative and visitor facilities would be relocated to the remaining area of the NWR. Public access would be restricted to portions of the NWR that overlap with the SDZs. The USFWS mission would be able to adapt to coexist with the change in land use and access restrictions. At the end of the lifespan of the proposed action, the access restrictions could be removed.

The short-term use of the land would have adverse impacts, but most of the impacts could be reversed to current conditions at the end of the lifespan of the proposed action. Current land use and access could be restored with no long-term loss of productivity and no impact on the range of options for future beneficial uses.

Land use changes outside the military installation would likely result from the economic growth associated with the additional population, potential development and activities that are created by the increased short-term spending associated with the proposed action, and over the longer term due to a more productive use of land than is taking place at present. This is similar to the induced growth that may be created as a consequence of improvements, particularly expansions, in transportation or other infrastructure that makes land more accessible and so increases the likelihood that this land would be developed or redeveloped. This land development and activities associated with induced growth could then contribute to both beneficial and adverse impacts on land use. Non-DoD land use development is subject to GovGuam agency approvals. The approval process considers the development proposal’s consistency with established land use planning objectives and would minimize the adverse impacts of new development on land use.

### 8.5.7 Recreational Resources

The proposed action would result in adverse impacts to marine and terrestrial recreational uses at South Finegayan, and within the land and submerged land affected by the LFTRC. At the end of the life of the proposed action, these uses could be resumed. There is a potential that the restricted or managed recreational use during the life of the proposed action could beneficially impact recreational resource health. There would be a beneficial impact under the restricted access imposed by the LFTRC SDZs extending over ocean bottom fisheries areas. Short- and long-term beneficial impacts to recreation would occur from a healthier fishery by increasing fish landings when the range is not in use and when the range no longer exists.

The increase in island population (direct, indirect, and induced) could result in the overuse of existing recreational resources in other island locations. Foreseeable impacts include inadequate or overcrowded facilities, such as parking, picnic shelters, restrooms, showers, boat mooring facilities, etc. Moreover, a decreased sense of enjoyment due to increased competition for opportunities among users would result at most recreational facilities (e.g., more people on trails, crowding at popular dive spots). An increase in the number of users would accelerate the deterioration of existing facilities. Furthermore, over the long-term, recreational resources would see a reduction in productivity due to increased use from population growth from both military relocation and from organic growth, unless these resources are properly maintained.

There would be long-term impacts on recreational resource productivity. Depending on the extent of the impact to recreational resource health, it is possible for the resources to recover at some point in the future.
after the lifespan of the proposed action has ended, and the range of options for future beneficial uses would be less than significantly affected.

### 8.5.8 Terrestrial Biological Resources

With implementation of the proposed action, large areas of primary and secondary native limestone forest would be removed, primarily associated with Overlay Refuge lands. Development of this limestone forest habitat within Overlay Refuge lands would represent a significant loss of recovery habitat for ESA-listed species including Mariana fruit bat, Mariana crow, Guam rail, Guam Micronesian kingfisher, and *Serianthes* tree.

Operational impacts would include noise, lighting, and other disturbance impacts on special-status species. Other long-term impacts could reduce habitat quality, such as the increased potential for fire and spread of non-native species. These would be balanced by the application of plans and procedures for wildland fire control and biosecurity, native forest enhancement, and by enlarging or creating new ERAs. Implementation of these plans would improve the overall quality of targeted habitat over current conditions by implementing ungulate management, control of invasive species, rodent and cat control, and restoration of native forests.

Potential effects on the Ritidian Unit of the Guam NWR and restricted access to lands within the SDZs could result in reduced access for monitoring, inventory surveys, habitat enhancement and restoration, and outreach activities.

The impacts of construction and operational activities of the proposed action would result in a loss of long-term productivity of terrestrial biological resources by limiting the range of future beneficial uses for these resources.

### 8.5.9 Marine Biological Resources

No in-water construction work is proposed for implementation of the proposed action. With the application of BMPs and LID plans, direct impacts on marine biological resources are expected to be less than significant. Reduced public access to submerged lands associated with the LFTRC SDZs would have a beneficial impact on marine biological resources.

The infrequency of bullets reaching the ocean and the reduced speed of the ricochet would result in less than significant direct impacts to marine animals within the SDZ. There would be long-term localized accumulation of small arms (no explosives) expended materials in the benthic habitat from the firing range operations. The rapid sinking rate of such munitions is expected to preclude ingestion by marine organisms. The operational impact of the LFTRC on marine resources would be less than significant, and no loss of long-term productivity for marine biological resources is expected. The proposed action would not reduce the range of options for future beneficial uses.

A beneficial impact on bottom fisheries would potentially occur due to restricted access under the Alternative 5 SDZ at NWF, thereby leading to a healthier fishery with increased fish yields when the range is not in use.

### 8.5.10 Cultural Resources

The proposed action would result in the direct loss and disturbance of NRHP-eligible sites. The potential for direct effects within the SDZ would be limited to the risk of strikes from stray rounds during range operations. The risk of such effects occurring is extremely low. The range would be designed to contain live fire inside the range itself to minimize the probability of rounds landing in the SDZ. Additionally, if a
stray round were to escape the range, the chance of it hitting a historic property is remote, given the size of the SDZ, natural topography, and dispersal of historic properties. For these reasons, the potential for direct adverse effects as a result of range operations is *de minimis*. There is potential for inadvertent or accidental damage to at least one NRHP-eligible site due to an increase in population in the area. The removal of limestone forest where culturally important natural resources may be located would also be required. With implementation of the processes and procedures in the 2011 PA, including data recovery, cultural awareness orientation briefs, and additional identification efforts, there would be a long-term benefit from the increase in knowledge of the past and the distribution of this knowledge to the public. However, at the end of the lifespan of the proposed action, the long-term productivity of cultural resources could be diminished, and the range of options for future beneficial uses may be affected.

8.5.11 Visual Resources

The proposed action would not substantially alter the views or scenic quality of significant and/or publicly recognized vistas, viewsheds, overlooks, or features; change the light, glare, or shadows within a given area; or affect sensitive receptors. At the end of the lifespan of the proposed action, facilities could be demolished and the built landscape altered. There would be no long-term loss of visual resource productivity, and the proposed action would not reduce the range of options for future beneficial uses.

8.5.12 Ground Transportation

There would be short-term adverse impacts on traffic associated with the proposed action and off-base roadway improvements are proposed that would benefit the civilian community. This benefit would extend beyond the life of the proposed action, for a positive long-term impact on ground transportation. The proposed action would not reduce the range of options for future beneficial uses and less than significant impacts to long-term productivity are expected.

8.5.13 Marine Transportation

The proposed action may affect marine transportation by impacting the military, commercial, and recreational navigational usage of Apra Harbor through the increased number of vessels. The impact was determined to be less than significant.

The LFTRC SDZ impacts a designated shipping lane used by all vessels traveling from Hawaii to Guam; however, this is considered a less than significant impact. The LFTRC SDZ would affect recreational and commercial tour navigation between Hagåtña Marina and areas north and east of Guam. The impact to navigation is considered less than significant because vessels can transit around the SDZ and through the SDZ when the range is not in operation.

At the end of the lifespan of the proposed action, the impacts of the proposed action would cease and there would be no long-term impacts on marine transportation capabilities. The proposed action would not reduce the range of options for future beneficial uses and less than significant impacts to long-term productivity are expected.

8.5.14 Utilities

Electrical power, potable water, and wastewater utility upgrades are required to support the proposed action. Some of the improvements to the GovGuam systems would benefit the community. This benefit would extend beyond the life of the proposed action, for a long-term positive impact on utility infrastructure. In addition, adding a substantial and reliable customer for wastewater, electrical power, and solid waste disposal services would provide GovGuam with needed long-term revenue to fund additional future upgrades to their utility infrastructure. The proposed action would not reduce the range
of options for future beneficial uses and less than significant impacts to long-term productivity are expected.

8.5.15 Socioeconomics and General Services

Beneficial impacts, adverse impacts, and significant impacts of a mixed nature are identified for the proposed action; however, the generalized conclusion for Population Change, Economic Activity, Public Services, and Sociocultural Issues categories is that there would not be major adverse changes to Guam’s existing socioeconomic infrastructure. The population change associated with the proposed action would not likely put excessive strain on most of Guam’s public services agencies, and the estimated increases in GovGuam tax revenues would likely compensate for any increased demand that would occur. The economic impacts would be beneficial, leading to increased employment and standards of living, and impacts to Guam’s housing stock and availability would not bring about reactionary development, which could have otherwise lead to dislocations in the housing market. Impacts to GovGuam public services are identified; impacts to some public service agencies are considered significant. These impacts are related to additional staffing required to meet demands from additional population that would be associated with the proposed action.

Once implementation of the proposed action is completed, the population would be reduced, with no long-term loss to the socioeconomic infrastructure. The proposed action would not reduce the range of options for future beneficial uses and less than significant impacts to long-term productivity are expected.

8.5.16 Hazardous Materials and Waste

The proposed action would result in the increased transportation, handling, use, and disposal of hazardous materials (e.g., POLs/fuels) and hazardous wastes (pesticides, herbicides, solvents, lubricants, heavy metals). However, through the use of various BMPs and SOPs, operational impacts would be minimal. At the end of the lifespan of the proposed action, there would be a net increase in the use, generation and disposal of hazardous materials and waste over current baseline conditions; however, continued adherence to BMPs and SOPs with regards to their management and continued efforts to minimize the use and generation of hazardous materials and waste during operations would reduce potential adverse impacts to less than significant. The proposed action would not reduce the range of options for future beneficial uses and less than significant impacts to long-term productivity are expected.

8.5.17 Public Health and Safety

The proposed action would result in an increased on-island population; however, no significant long-term risks to health, safety, or the general welfare of the public were identified.

At the end of the lifespan of the proposed action, there would be no residual impact to public health and safety. The proposed action would not reduce the range of options for future beneficial uses and less than significant impacts to long-term productivity are expected.

8.5.18 Environmental Justice and the Protection of Children

Environmental justice examines the potential for adverse impacts to disproportionately affect socially disadvantaged groups, including racial minorities, low-income populations, and children. There likely would be disproportionate significant public health services effects on low-income populations. Guam’s public health services would not be able to handle potential increases in illnesses of the medically underserved and low income at the current levels of staffing. Access to public health and social services would be additionally strained by an increase in uninsured and underinsured workers coming to Guam.
At the end of the lifespan of the proposed action, there would be no residual long-term impact to public health and safety. The proposed action would not reduce the range of options for future beneficial uses and less than significant impacts to long-term productivity are expected.

### 8.6 Sustainability and Smart Growth

DoD policy is to address sustainability concepts in acquisition and procurement processes and in planning and managing its installations. For every DoD program, the Department actively seeks opportunities to continually improve its activities, and continues to develop and improve methodologies to ensure systematic analysis, informed decision-making, and appropriate budgets to address sustainability in accordance with the 2012 DoD Strategic Sustainability Performance Plan. Marine Corps policy on sustainability, presented in the 2011 U.S. Marine Corps Sustainability Plan, aligns with the priorities, direction, and scope of the DoD Strategic Sustainability Performance Plan.

DoD has implemented sustainability measures on Guam, such as solar photovoltaic arrays and solar water heating. Ongoing energy efficiency efforts include smart metering and controls (building and utility control systems, peak load monitoring, etc.), solar street lights and parking/playground lighting, low flow fixtures, and new and retrofitted buildings to LEED Silver (or equivalent) design standards.

The 2010 Final EIS (Volume 8, Chapter 6, Sustainability and Smart Growth) provides a summary of sustainability goals, including an overview (laws, regulations and guidance, and the DON’s energy policy), implementation strategies, and anticipated results (e.g., reductions in water use, energy use, greenhouse gas emissions, vehicle miles traveled, and plans to implement renewable energy). Those sustainability goals and potential strategies were identified based on studies conducted for the 2010 Final EIS. The studies were shaped by smart growth and sustainability workshops for DoD stakeholders to identify specific elements to be included in the concept plan for the proposed action, with a primary focus on the preferred cantonment/family housing area in the 2010 Final EIS.

The DON conducted a new sustainability analysis for the 2012 Roadmap Adjustments SEIS. The new analysis addressed the smaller force, reduction in size of the cantonment and family housing areas, and locations of the cantonment and family housing alternatives. The study identified strategies for each primary system - water, energy (building, district, renewable and public realm), green building/LEED and transportation. Plans for each primary system were adjusted to achieve environmental benefit in a cost-effective manner. Identified strategies will be incorporated, as appropriate, into the design and implementation phases to support meeting federal sustainability mandates.

For the proposed action, DoD has identified potential sustainability strategies and measures to meet federal mandates and to achieve the following target goals set for 2020: 30% energy use reduction, 26% water use reduction, 30% reduction of petroleum use in fleet vehicles, 18.3% of total energy from renewable sources, 34% reduction in greenhouse gas emissions, and diversion of 50% of non-hazardous solid waste and 60% of construction and demolition debris from the waste stream. DoD’s goal is to meet federal sustainability mandates for the new Marine Corps installation on Guam. The Marine Corps has developed goals in their 2011 Sustainability Plan to meet these mandates: Goal 1 - Improve energy and water resources management and reduce greenhouse gases; Goal 2 - Minimize waste and prevent pollution; and Goal 3 - Improve integration of sustainability practices across all missions areas.

High Performance and Sustainable Building Requirements (UFC 1-200-02) the U.S. Green Building Council LEED Reference Guide for Green Building Design and Construction, and LEED New Construction Rating System are included in the DON’s design and construction contracts to meet federal
sustainability mandates. The Guiding Principles for Sustainable New Construction and Major Renovation
provides guidance on employing integrated design principles, optimizing energy performance, protecting
and conserving water, enhancing indoor environmental quality, and reducing environmental impact of
materials. For new construction, reduction of energy and water usage is compared to the baseline building
performance per established performance standards and requirements. Sustainability strategies for
building energy reduction, renewable energy opportunities, water conservation measures, greenhouse gas
reduction, and waste reduction are summarized below. Based on these strategies, the new Marine Corps
installation on Guam will strive to meet sustainability mandates and DoD goals, including the net-zero
energy installation goal (an installation that produces as much energy on site as it uses, over the course of
a year).

8.6.1 Energy Reduction

The sustainability strategy for energy reduction is to implement energy conservation measures on
appropriate buildings under the proposed action. These include: building control systems for lighting,
light emitting diode exterior lighting, highly efficient windows, thermal insulation, more efficient fans
and pumps, other technologies to reduce the cooling load of buildings, and the use of energy star
appliances. In addition, industrial control systems, advanced meters, utility and building control systems,
industrial control systems infrastructure (hardware, software, communication pathways), smart meters,
direct digital control, and other Smart Grid components would be implemented to provide power, to allow
monitoring and control systems for more efficient energy usage and to enable energy management.

8.6.2 Renewable Energy

On-site renewable energy would be provided when lifecycle cost is cost-effective and technically feasible
in accordance with DoD guidance. For the proposed Marine Corps installation on Guam, combined
building-mounted renewables and/or ground-mounted solar photovoltaic arrays are being considered and
will be installed based on results of the feasibility study that the DON is currently conducting to
determine if rooftop, adhered photovoltaic systems are economically viable and capable of withstanding
typhoon conditions in Guam’s corrosive environment. The proposed Marine Corps installation would
partner with JRM to achieve renewable energy mandates through either an installation or regional
approach using large-scale solar photovoltaic, wind, and/or other renewable resources. A portion of the
power demand would be satisfied by power generated from renewable energy sources, to include
photovoltaic solar panels on rooftops and approximately 20 acres (8 ha) within the cantonment and/or
family housing footprints proposed for ground-mounted photovoltaic panels. JRM has initiated a regional
approach to achieve renewable/alternative energy goals and would cooperate with GPA to further develop
the island-wide energy demand side management and energy efficiency via renewable energy project(s)
on DON-controlled land (DON 2014).

8.6.3 Water Conservation Measures

DoD would implement water conservation measures to meet indoor water use reduction mandates. Water
conservation measures include low-flow water fixtures and dual flush toilets. Other potential strategies
may include rain water harvesting, condensate collection from heating, ventilation, and air conditioning
units and grey water collection in cisterns for additional water supply. Outdoor water conservation
measures are also being considered such as reduction or elimination of irrigation systems, and use of
native plants for landscaping.
8.6.4 Transportation

Potential strategies to reduce vehicle miles traveled and greenhouse gas emissions include the following:

- Use of more fuel-efficient or alternative-fuel vehicles with a fuel efficiency of at least 28.7 mpg (12.2 km/liter) or higher.
- Reduction in the number of employee commuting vehicle trips through carpooling incentives, and live-where-you work community design.
- Consider establishing a shuttle bus system to reduce traffic and improve circulation if deemed necessary.
- Design a transportation network with special consideration for pedestrians and bicyclists.
- Use of mass transit by UDP (rotational) personnel instead of privately-owned vehicles.
- Selection of the cantonment/family housing and LFTRC alternatives combination that would result in reduced travel distances.

8.6.5 Waste

The waste reduction mandates would be met through implementation of the following strategies:

- Maintenance and expansion of installation or regional recycling programs throughout the proposed Marine Corps cantonment/family housing.
- Construction of new recycling and transfer facilities at the proposed cantonment/family housing.
- Adequate laydown and processing areas in contract specifications to allow diversion of green waste (including composting), concrete, and asphalt rubble from landfill disposal.
- Requirement in the contract specifications to meet federal mandates for waste diversion during construction, including submittal of a waste management plan and reporting of waste diversion.

http://guambuildupnews.com/Real-Estate/Guams-Largest-Workforce-Housing-Complex-Opens-
January 8, 2013.

9.5.16 Hazardous Materials and Waste

9.5.17 Public Health and Safety

9.5.18 Environmental Justice and the Protection of Children

9.6 CHAPTER 5

9.6.1 Geological and Soil Resources

NRCS. 2006. Soil survey area GIS data for the Territory of Guam. Downloaded from the NRCS Soil Data Mart. Tabular version dated December 31.

WERI. 2001. GIS Data for Sinkholes and Depressions on Guam.

9.6.2 Water Resources

WERI. 2001. GIS Data for Sinkholes and Depressions on Guam.

9.6.3 Air Quality

9.6.4 Noise

NAVFC PACIFIC. 2013. GIS Data provided by NAVFC PACIFIC via email. May 2013.

9.6.5 Airspace

9.6.6 Land and Submerged Land Use

9.6.7 Recreational Resources

9.6.8 Terrestrial Biological Resources

NAVFAC Pacific. 2013c. GIS Data provided by NAVFAC Pacific via email. May.

USFWS. 1990. Mariana Fruit Bat (Guam Population) and Little Mariana Fruit Bat Recovery Plan. Region 1, Portland, OR. November 2.

USFWS. 2009a. Draft Revised Recovery Plan for the Mariana Fruit Bat or Fanihi (Pteropus mariannus mariannus). Portland, OR.

USFWS. 2014c. Property Record for Ritidian Unit, Guam National Wildlife Refuge. Provided by the Chief of Division of Realty, USFWS. December 4.

### 9.6.9 Marine Biological Resources

NOAA. 2005b. Guam Coastal Atlas. Maps prepared by David Burdick, the 2004-2006 NOAA Pacific Islands Assistant for Guam, under the supervision of Terry Donaldson, Ph.D., and Barry Smith, M.Sc., of the University of Guam Marine Laboratory and with the support of the Guam Coastal Management Program and the NOAA Pacific Services Center. November.

### 9.6.10 Cultural Resources

### 9.6.11 Visual Resources

AECOM. 2009. View looking east across NAVMAG near the top of the Lamlam Trail.

AECOM. 2010a. View of the existing Route 15 northbound.

AECOM. 2010b. View of the existing Route 15 southbound.

AECOM. 2010c. View of Route 3A descending to the Guam NWR Nature Center at Ritidian Point - NWF.

### 9.6.12 Ground Transportation

### 9.6.13 Marine Transportation

No references cited in this section.

### 9.6.14 Utilities

No references cited in this section.

### 9.6.15 Socioeconomics and General Services

9.6.16 Hazardous Materials and Waste

9.6.17 Public Health and Safety

9.6.18 Environmental Justice and the Protection of Children

No references cited in this section.

9.7 CHAPTER 6

Hunter-Anderson, R. 2002. An Archaeological Study of the Togcha Beach, Agat Burial Recovery Trench, the Tycom Cable Station and Regional Operating Center in Piti and a Report on the Archaeological Monitoring of Cable Trenching along Marine Drive, Route 2A and Route 2 from Piti to Biyae, Agat, and At Cable Landing Sites in Piti and Agat. Prepared for M.A. Mortenson Company. Minneapolis, Minnesota.

Kurashina, H., T. McGrath, and H. Manner. 1987. Archaeological Survey of Areas 1, 2, 1A, and 2A at Northwest Field, Andersen Air Force Base and Naval Communication Area Master Station Western Pacific, Finegayan, Guam, Marianas Islands. Prepared for NAVFAC Pacific by University of Guam, Mangilao and B.P. Bishop Museum, Honolulu, HI.

Olmo, R., T. Mangieri, D. Welch, and T. Dye. 2000. Phase II Archaeological Survey and Detailed Recording at Commander, U.S. Naval Forces Marianas (COMNAVMARIANAS), Communications Annex (Formerly Naval Computer and Telecommunications Area Master Station, Western Pacific [NCTAMS WESTPAC]), Territory of Guam, Marianas Islands. Prepared for the NAVFAC Pacific, Pearl Harbor, HI, by the International Archaeological Research Institute, Inc., Honolulu, HI.

9.8 CHAPTER 7

NAVFAC Pacific. 2013c. GIS Data provided by NAVFAC Pacific. May.

9.9 CHAPTER 8

CHAPTER 10
LIST OF PREPARERS

10.1 GOVERNMENT PREPARERS

Albert Borja (Naval Facilities Engineering Command, Marianas), Environmental Compliance Specialist, 
B.A., Biology

Patrick Castello (Marine Forces Pacific), Aviation Training Analyst
Master of Business Administration

J. Dan Cecchini (Assistant Secretary of the Navy - Energy, Installations & Environment; Joint Guam 
Program Office), JGPO Environmental Director 
B.S. Forestry & Wildlife

Coralie Cobb (Naval Facilities Engineering Command, Southwest), Fish and Wildlife Biologist 
B.A., General Biology

Patricia Conte (Naval Facilities Engineering Command, Pacific), Archaeologist 
M.A., Anthropology (Pacific Anthropology)

Jennifer Farley (Naval Facilities Engineering Command, Marianas), Supervisory Fish and Wildlife 
Biologist 
Master of Applied Science, Zoology: Wildlife Biology and Management

Kyle Fujimoto (Naval Facilities Engineering Command, Pacific), Navy Technical Representative 
B.S., Industrial Engineering

Sean Hanser (Naval Facilities Engineering Command, Pacific), Natural Resources Management Specialist 
for Marine Resources 
Ph.D., Ecology 
B.S., Marine Biology

Joel Helm (Naval Facilities Engineering Command, Pacific), Navy Technical Representative 
B.S., Wildlife Biology

Darlene Ige (Naval Facilities Engineering Command, Pacific), Guam Program Management Office 
Environmental Business Line Team Lead

Natalie Latham (Pacific Division, Headquarters Marine Corps Plans, Policies & Operations), Action 
Officer, 
MCP, City Planning and Urban Design

Matthew Lemire (Marine Corps Installation Command) Environmental Specialist 
Post Baccalaureate, Environmental Management 
B.A., Geography

William Manley (Naval Facilities Engineering Command, Headquarters), Senior Advisor on Cultural 
Resources 
M.A. Organizational Leadership 
B.A. American History
Kay Chang-Minami (Naval Facilities Engineering Command, Pacific), Guam Program Management Office Acting Public Works Business Line Team Lead  
M.S. Public Health, Environmental Science/Toxicology

Dean Patterson, Col (Pacific Division, Headquarters Marine Corps Plans, Policies & Operations) Branch Head  
M.A. Education

Michael Paulovich (Marine Corps Installations Command) Future Plans Officer  
Masters of Business Administration

Randel Sablan (Joint Guam Program Office, Assistant Secretary of the Navy - Energy, Installations and Environment), Environmental Director  
B.S., Forest Recreation Resources Management  
M.S., Environmental Management

Jennifer Scarborough (Joint Guam Program Office)  
B.S. Wildlife Management and Forestry

Suni Shrestha (Joint Guam Program Office), Environmental Analyst - Consultant  
B.S., Environmental Analysis and Planning

Bryan Swenson, LtCol (Pacific Division, Headquarters Marine Corps Plans, Policies & Operations) U.S. Marine Corps Training and Aviation Officer  
M.S., Military Studies  
B.S., Mechanical Engineering

10.2 CONTRACTOR PREPARERS

Maggie Bach (Cardno TEC, Inc.), Geology  
B.A., Geology  
Years of Experience: 20

Craig Bloxham (Cardno TEC, Inc.), Project Manager  
M.A., Geography  
Years of Experience: 26

Karen Breitlow (Cardno TEC, Inc.), Marine Biological Resources and Administrative Record  
M.S., Biological Sciences  
Years of Experience: 4

Chris Briskorn (AECOM), Utilities-Communications  
B.S., Engineering  
Years of Experience: 15

Jackie Brownlow (Cardno TEC, Inc.), Technical Editing  
B.S., Business Administration, Management, and Operations  
Years of Experience: 6

Brian Brownworth (AECOM), Air Quality  
M.S., Environmental Engineering  
Years of Experience: 10
Selena Buoni (Cardno TEC, Inc.), Environmental Justice  
Master of Planning (MPL), Sustainable Land Use  
Years of Experience: 9

Jim Campe (Cardno TEC, Inc.), Noise  
B.S., Naval Architecture and Off-Shore Engineering  
Years of Experience: 27

Faith Caplan (Cardno TEC, Inc.), AICP, Land Use  
M.A., Public Health  
Years of Experience: 21

Jeff Chan (AECOM), Transportation-Roads  
M.E., Civil and Environmental Engineering, Transportation Systems Engineering  
Years of Experience: 13

Helen Chernoff (AECOM), Air Quality  
M.S., Biological Sciences  
Years of Experience: 27

J. Scott Coombs (Cardno TEC, Inc.), Water Resources  
M.S., Marine Sciences  
Years of Experience: 15

Christine Davis (Cardno TEC, Inc.), NEPA Analyst  
M.S., Environmental Management  
Years of Experience: 14

Pete Diaz (AECOM), Utilities-Wastewater  
M.S., Civil and Environmental Engineering  
Years of Experience: 7

Robert Forstner (AECOM), Air Quality  
M.E., Civil/Environmental Engineering  
Years of Experience: 14

Erica Fuery (Cardno TEC, Inc.), Hazardous Materials and Waste  
M.S., Environmental Science  
Years of Experience: 14

Christine Granger (AECOM), Technical Editor  
M.S., Technical Communication Management  
Years of Experience: 14

William Halperin, Ph.D. (Cardno TEC, Inc.), Program Director and Quality Assurance/Quality Control  
Ph.D., Geography  
Years of Experience: 29

David Harnsberger (AECOM), GIS  
M.S., Geological Science  
Years of Experience: 3
Renee Harrington (Cardno TEC, Inc.), NEPA Analyst
  *M.S., Marine Science*
  *Years of Experience: 10*

Jason Harshman (Cardno TEC, Inc.), GIS
  *B.A., Geography*
  *Years of Experience: 8*

Landin Johnson (AECOM), Visual
  *Master of Urban and Regional Planning*
  *Years of Experience: 9*

Dave Jury (AECOM), Public Health and Safety
  *B.A., Geography*
  *Years of Experience: 25*

David Kiernan (Cardno TEC, Inc.), Socioeconomics
  *Masters in Urban and Regional Planning*
  *Years of Experience: 12*

Steve Keith (AECOM), Utilities
  *M.S., Civil Engineering*
  *Years of Experience: 41*

Amanda Leahy (AECOM), Transportation-Roads
  *B.A., Geography and Urban Studies*
  *Years of Experience: 6*

James Mansky (AECOM), Transportation-Marine
  *M.S., Zoology/Botany*
  *Years of Experience: 25*

Andrew Martin (AECOM), Transportation-Marine
  *M.S., Ecology*
  *Years of Experience: 12*

Ben Mascardo (AECOM), Utilities-Electrical
  *B.S., Electrical Engineering*
  *Years of Experience: 40*

Kari McManus (AECOM), Technical Editor
  *B.A., Spanish*
  *Years of Experience: 14*

Dan McNair, CAPT (Ret.), Joint Venture Program Manager
  *M.S., Civil Engineering/Environmental*
  *Years of Experience: 28*

Jeff Merz (AECOM), AICP, Recreation and Visual
  *B.S., Urban and Regional Planning/Geography*
  *Years of Experience: 22*
Marian Nakama (AECOM), Utilities-Water
   B.S., Civil Engineering
   Years of Experience: 19

Patrick Ono (AECOM), Utilities-Solid Waste
   M.S., Systems Management
   Years of Experience: 40

Priyal Pandya (AECOM), Air Quality
   M.S., Environmental Engineering
   Years of Experience: 3

Teresa Rudolph (Cardno TEC, Inc.), Cultural Resources
   M.A., Anthropology
   Years of Experience: 34

Jennifer Scheffel (AECOM), Deputy Project Manager
   Master of Applied Geography
   Years of Experience: 13

Rick Spaulding (Cardno TEC, Inc.), Terrestrial Biological Resources
   M.S., Wildlife and Fisheries Science
   Years of Experience: 29

Claudia Tan (Cardno TEC, Inc.), Technical Editor/Production Manager
   A.A., Liberal Arts and Sciences
   Years of Experience: 14

Bob Wardwell (Cardno TEC, Inc.), Technical Reviewer
   M.S., Environmental Science
   Years of Experience: 35

Bill Wear, Col (Ret.), Airspace
   M.A., Public Administration
   Years of Experience: 43

Kerry Wells (Cardno TEC, Inc.), GIS
   B.S., Physics
   Years of Experience: 12

Fang Yang (AECOM), Air Quality
   M.S., Atmospheric Science
   Years of Experience: 24

Julie Zimmerman (AECOM), Public Meetings
   B.A., Environmental Studies and English
   Years of Experience: 7
